Table 15-122. EMIF SDRAM Self-Refresh (continued)

Step	Register/Bit Field/Programming Model	Value
Enable self-refresh mode.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x2

15.3.5.1.2.6 EMIF LPDDR2 (SDRAM or NVM) Power-Down Mode

Table 15-123. EMIF SDRAM Power-Down Mode

Step	Register/Bit Field/Programming Model	Value
Define minimum number of DDR clock cycles from power-down exit to any command other than a read command.	EMIF_SDRAM_TIM_2[30:28] REG_T_XP	0x-
Write the shadow register of EMIF_SDRAM_TIM_2.	EMIF_SDRAM_TIM_2_SHDW	EMIF_SDRAM_TIM_2
Define the number of DDR clock cycles after which the external memory will be put in power-saving mode when the EMIF enters idle mode.	EMIF_PWR_MGMT_CTRL[3:0] REG_CS_TIM	0x-
Enable (enter) power-down mode.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x4

15.3.5.1.2.7 EMIF LPDDR2-SDRAM Deep Power-Down Mode

Table 15-124. EMIF LPDDR2-SDRAM Deep Power-Down Mode

Step	Register/Bit Field/Programming Model	Value
Define minimum number of DDR clock cycles from power-down exit to any command other than a read command.	EMIF_SDRAM_TIM_2[30:28] REG_T_XP	0x-
Write the shadow register of EMIF_SDRAM_TIM_2.	EMIF_SDRAM_TIM_2_SHDW	EMIF_SDRAM_TIM_2
Define the number of DDR clock cycles after which the external memory will be put in power-saving mode when the EMIF enters idle mode.	EMIF_PWR_MGMT_CTRL[3:0] REG_CS_TIM	0x-
Enable (enter) deep power-down mode.	EMIF_PWR_MGMT_CTRL[11] REG_DPD_EN	0x1

15.3.5.1.2.8 EMIF Global Warm Reset (Software Reset)

Table 15-125. EMIF Global Warm Reset (Software Reset)

Step	Register/Bit Field/Programming Model	Value
IF: External request for reset	Input signal EMIFi_GLOBAL_RST	Asserted (see the programming model in the PRCM chapter)
Follow the sequence in Section 15.3.5.1.2.5 *EMIF SDRAM Self-Refresh Sequence*.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x2
ELSE:	Input signal EMIFi_GLOBAL_RST	Deasserted (see the programming model in the PRCM chapter)
Disable (exit) self-refresh mode when not needed.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x0
ENDIF		

15.3.5.1.2.9 EMIF Temperature Monitoring Mode

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Table 15-126. EMIF Temperature Monitoring Mode

Step	Register/Bit Field/Programming Model	Value
Determine whether CS1 or CS0 will be used for temperature alert polling.	EMIF_TEMP_ALERT_CONFIG[31:30] REG_TA_CS1/0EN	0x-
Define the interval (number of refresh periods) between temperature alert polls.	EMIF_TEMP_ALERT_CONFIG[21:0] REG_TA_REFINTERVAL	0x------
Define how wide the physical memory device will be.	EMIF_TEMP_ALERT_CONFIG[27:26] REG_TA_DEVWDT	0x-
Define which external byte lanes will contain a device for temperature monitoring (which devices to be polled).	EMIF_TEMP_ALERT_CONFIG[25:24] REG_TA_DEVCNT	0x-
Enable system L3 interrupt for SDRAM temperature alert.	EMIF_IRQENABLE_SET_SYS[1] REG_EN_TA_SYS	0x1
Enable low-latency L3 interrupt for SDRAM temperature alert.	EMIF_IRQENABLE_SET_LL[1] REG_EN_TA_LL	0x1
Enable the issuing of a temperature alert poll on self-refresh exit (poll for temperature change every time EMIF exits self-refresh, active power-down, and precharge power-down modes).	EMIF_TEMP_ALERT_CONFIG[28] REG_TA_SFEXITEN	0x1

15.3.5.1.3 EMIF Events Servicing

15.3.5.1.3.1 Interrupt Servicing

This section describes event servicing (interrupt treatment) of the EMIF module.

The following Interrupt mechanism is double, because there are two EMIF modules with different register addresses and two Interrupt lines, EMIF1_IRQ and EMIF2_IRQ.

Table 15-127. EMIF Event Servicing

Step	Registe/Bit Field/Programming Model	Value
Clear all eventual previous indications of treated interrupts, and write the four registers:	EMIF_IRQSTATUS_SYS, EMIF_IRQSTATUS_LL, EMIF_IRQSTATUS_RAW_SYS, EMIF_IRQSTATUS_RAW_LL	0x0000003
Enable the system L3 interrupts.	EMIF_IRQENABLE_SET_SYS	0x0000003
Enable the low-latency L3 interrupts.	EMIF_IRQENABLE_SET_LL	0x0000003
Wait until an event occurs.		
Read the status registers:	EMIF_IRQSTATUS_SYS, EMIF_IRQSTATUS_LL, EMIF_IRQSTATUS_RAW_SYS, EMIF_IRQSTATUS_RAW_LL	
IF: the EMIF_IRQSTATUS_SYS[0] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for system L3 – Command/address error.	INTC of the MPU	
ELSE IF: the EMIF_IRQSTATUS_SYS[1] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for system L3 – Temperature alert.	INTC of the MPU	
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
ELSE IF: the EMIF_IRQSTATUS_RAW_SYS[0] = 1		

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Table 15-127. EMIF Event Servicing (continued)

Step	Registe/Bit Field/Programming Model	Value
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for raw system L3 – Command/address error.	INTC of the MPU	
ELSE IF: the EMIF_IRQSTATUS_RAW_SYS[1] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for raw system L3 – Temperature alert	INTC of the MPU	
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
ELSE IF: the EMIF_IRQSTATUS_LL[0] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for low-latency L3 – Command/address error.	INTC of the MPU	
ELSE IF: the EMIF_IRQSTATUS_LL[1] =1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for low-latency L3 – Temperature alert.	INTC of the MPU	
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
ELSE IF: The EMIF_IRQSTATUS_RAW_LL[0] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for raw low-latency L3 – Command/address error	INTC of the MPU	
ELSE: The EMIF_IRQSTATUS_RAW_LL[1] = 1		
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction:	EMIF_L3_ERR_LOG	
Start the interrupt handler for raw low-latency L3 – Temperature alert.	INTC of the MPU	
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
ENDIF		
Wait until the termination of the corresponding interrupt handler.	IINTC of the MPU	
IF: Address/command error was treated		
Clear the LSB in the relevant IRQ status registers, SYS or LL; write both registers:	EMIF_IRQSTATUS_SYS[0] REG_ERR_SYS and EMIF_IRQSTATUS_RAW_SYS[0] REG_ERR_SYS, or EMIF_IRQSTATUS_LL[0] REG_ERR_LL and EMIF_IRQSTATUS_RAW_LL[0] REG_ERR_LL	0x1
Disable the corresponding interrupt if needed; write:	EMIF_IRQENABLE_CLR_SYS[0] REG_EN_ERR_SYS or EMIF_IRQENABLE_CLR_LL[0] REG_EN_ERR_LL	0x1
ELSE: (Temperature alert proceeded)		

PRELIMINARY

EMIF_DDR_PHY_CTRL_1_SHDW	RW	32	0x0000 00E8	0x4C00 00E8	0x4D00 00E8
EMIF_DDR_PHY_CTRL_2	RW	32	0x0000 00EC	0x4C00 00EC	0x4D00 00EC

NOTE: The values of the different bit fields in the EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG2 registers are fixed by the control module at reset. These values must be modified by the header feature in the ROM code configuration or by the initial boot image running from an external XIP booting memory or internal RAM (see Section 27.4.8, *Image Format*). They must not be modified during run time, because they reflect the used hardware LPDDR2 SDRAM and/or NVM memory configurations.

15.3.6.2.2 EMIF Register Description

Table 15-130 through Table 15-213 describe the individual EMIF registers.

Table 15-130. EMIF_MOD_ID_REV

Bits	Field Name	Description	Type	Reset
9:7	REG_ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS field is set to 1, 2, or 3 or REG_EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x- (3)
6:4	REG_IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x- (3)
3	REG_EBANK	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0]. This bit will automatically be set to 0 if EMIF_SDRAM_CONFIG_2[30] REG_CS1NVMEN field is set to 1.	RW	0x- (3)
2:0	REG_PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x- (3)

(3) Value fixed by the control module at reset

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:12	REG_PD_TIM	Power Mangement timer for Power-Down. The EMIF will put the external SDRAM in Power-Down mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 4. Set to 0 to immediately enter Power-Down mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
11	REG_DPD_EN	Deep Power Down enable. Set to 0 for normal operation. Set to 1 to enter deep power-down mode. This mode will override the reg_lp_mode field setting.	RW	0
10:8	REG_LP_MODE	Automatic Power Management enable Set to 1: Reserved Set to 2: Self-refresh mode Set to 4: Power-down mode All other values will disable automatic power management.	RW	0x0
7:4	REG_SR_TIM	Power Mangement timer for Self Refresh. The EMIF will put the external SDRAM in Self Refresh mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 2. Set to 0 to immediately enter Self Refresh mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
3:0	REG_CS_TIM	Power Mangement timer for Clock Stop. The EMIF will put the external SDRAM in Clock Stop mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 1. Set to 0 to immediately enter Clock Stop mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0

RESERVED	REG_SYS_THRESH_MAX	RESERVED	REG_LL_THRESH_MAX	RESERVED	REG_PR_OLD_COUNT

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved for future use.	R	0x0
27:24	REG_SYS_THRESH_MAX	System L3 Threshold Maximum. The number of commands the system interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1. Since the low-latency interface has effectively a higher priority, the only way for the system interface to use all command FIFO entries is to set the REG_LL_THRESH_MAX to zero.	RW	0x7
23:20	REG_MPU_THRESH_MAX	MPU Interface Threshold Maximum. The number of commands the MPU interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1.	RW	0x7
19:16	REG_LL_THRESH_MAX	Low-latency L3 Threshold Maximum. The number of commands the low latency interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1.	RW	0x7
15:8	RESERVED	Reserved for future use.	R	0x0
7:0	RESERVED	Although this field is reserved, it is still read writable. Values written have no effect on operation of the EMIF4D3.	RW	0xFF

PRELIMINARY

Table 15-178. Performance Counter Filter Configuration (continued)

CNTRn_CFG	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x7	0x0	0x0	Count number of EMIF_FCLK clock cycles L3 Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priotity elevations
0x9	0x0	0x0	Count number of EMIF_FCLK clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_FCLK clock cycles for which the memory data bus was transferring data.
0xB - 0xF	0x0	0x0	Reserved for future use.

NOTE: When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that particular command if the CNTRn_CFG values are equal 0x0, 0x1, 0x2, 0x3, or 0xA.

Table 15-178 shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a L3 master ID and/or an external chip select to obtain performance statistics for a particular L3 master and/or an external chip select.

The EMIF clock frequency is half the DDR speed.

15.4 General-Purpose Memory Controller

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- Figure 15-50 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device (Figure 15-50).
- Figure 15-50 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device (Figure 15-51).
- Figure 15-52 shows a connection between the GPMC and a 16-bit NAND device (Figure 15-52).

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_ad[7:0] data bus (rather than D[15:8] / gpmc_ad[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

gpmc_a[25:16]	O	Address
gpmc_ad[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	O[(1)]	Clock generated for the external memory or device
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Upper-byte enable (active low).
gpmc_nwp	O	Write protect (active low)
gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.
gpmc_io_dir	O	gpmc_ad[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

(1) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

gpmc_ad[0]	A1/D0	D0	D0	D0

When using non-multiplexed memories, it is recommended to enable GPMC_CONFIG[1] LIMITEDADDRESS. This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2Kbytes of memory address space is accessible regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

NOTE: The numbering for A (address) is starting from 1 instead of 0 such as D (data) because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is only relevant to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible, that is, each 16-bit aligned 8-bit word is mapped but not the non-16-bit aligned ones. Any access to a non-aligned one will actually result in accessing the associated aligned one, at address A1 instead of address A.

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the Cortex-A9 MPU Interrupt Controller (MA_IRQ) and to DSP subsystem (D_IRQ)
- One clock for functional and interface domains

Figure 15-53 shows GPMC integration.

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

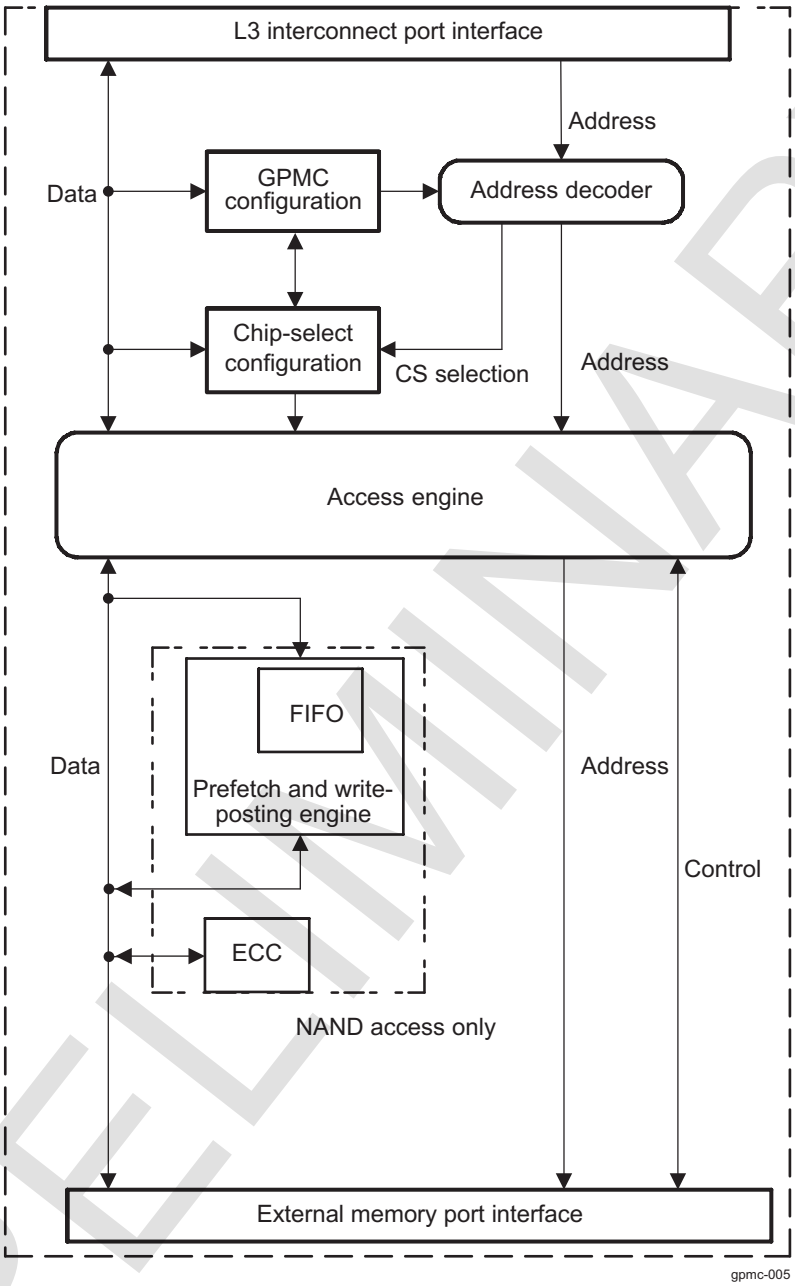
Figure 15-54 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-54. GPMC Block Diagram



The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

15.4.4.2 GPMC Clock Configuration

Table 15-220 describes the GPMC clocks.

PRELIMINARY

Table 15-220. GPMC Clocks

Signal	I/O [1]	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices.

(1) I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 15-218. The gpmc_clk is configured via the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field (for i = 0 to 7) as shown in Table 15-221.

Table 15-221. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

Table 15-222 describes power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 15-222. GPMC Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

PRELIMINARY

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in Figure 15-53 :

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A9 MPU subsystem : MA_IRQ_20 and to the DSP susbsystem : D_IRQ_59.

Table 15-223 lists the event flags, and their mask, that can cause module interrupts.

Table 15-223. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through GPMC_CONFIG[10] WAIT2PINPOLARITY
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	D_IRQ_59 and MA_IRQ_20	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches zero
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	D_IRQ_59 and MA_IRQ_20	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE shall be set to 0.

15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event as shown in Figure 15-53 :

- From GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 16 x 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 x 32, 4 x 32, 8 x 32 or 16 x 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field (GPMC_CONFIG1_i[24:23]) according to the effective attached device page length and to enable WRAPBURST bit (GPMC_CONFIG1_i[31]) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2 Kbytes.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, A26-A11 are not modified during an external memory access. This limits the memory address space to 2K-byte regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[25:16].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[25:16] and GPMC I/O: gpmc_ad[15:8].

CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

15.4.4.8.1 GPMC I/O Configuration Setting

NOTE: In this section and next sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b10
- GPMC_CONFIG1_i[9:8] MUXADDDATA bit = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA bit = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA bit = 0b01

To select an address/data-nonmultiplexed device (limited to a 2K-byte address range), program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA bit = 0b00
- GPMC_CONFIG[1] LIMITEDADDRESS bit = 1

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

NOTE: The GPMC_CONFIG[1] LIMITEDADDRESS bit only applies to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

15.4.4.8.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Additional pins are used to configure reset values in the GPMC_CONFIG1_i register (where i = 0) as detailed below and in Table 15-224:
  - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC_CONFIG1_i[13:12] DEVICESIZE bits (where i = 0). The BOOT_DEVICE_TYPE signal is propagated from the system control module (SCM). Its value is fixed for the device at 0x1 at IC reset, which means that only 16-bit memories are supported for booting.
  - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether the attached device to chip-select 0 is an address/data-multiplexed device or not. The input pin is used to configure the GPMC_CONFIG1_i[9:8] MUXADDDATA bit (where i = 0). The CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed for the device at 0x2 at IC reset, which means that only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
  - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_ENABLE signal is propagated from the system control module (SCM). When sys_boot[5:0] = 0b11 1111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read accesses.
  - The *bootwaitselect* input pin selects the WAIT signal at IC reset release time between WAIT0 input pin, WAIT1 input pin or WAIT2 input pin. At IC reset release time, these three pins have different polarity.

Table 15-224. Boot Control Interface Input Signals Description

Signal Name	Width	Description
bootdevicesize	2	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved
cs0muxdevice	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/Data-multiplexed device on CS0 0b11: Reserved
bootwaiten	1	Wait monitoring on CS0 at IC reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored
bootwaitselect	1	Selection of the wait pin 0: WAIT0 intput pin 1: WAIT1 intput pin 2: WAIT2 intput pin

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbytes address range device attached to CS0

At reset time, the IC may boot from the internal ROM.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0] while the high-order bits are presented both onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edge. The first rising edge latches the address MSB down to bit 17 while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 15.4.7,*GPMC Register Manual* provides the GPMC register locations. For the map of GPMC memory locations, see Chapter 2 , *Memory Mapping*.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

PRELIMINARY

15.4.4.9.1 Chip-Select Base Address and Region Size

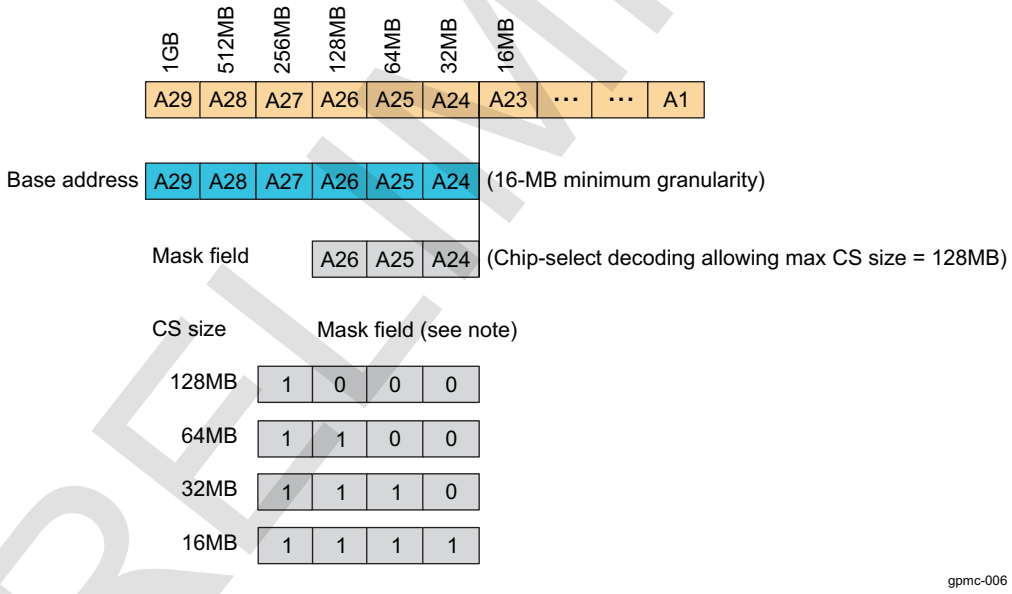
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see Chapter 2, *Memory Mapping*.

The GPMC 1G byte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16M bytes to 128M bytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 15-55 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 15-55. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, i = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Copyright © 2011, Texas Instruments Incorporated

CAUTION

Although the GPMC interface can drive up to 4 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

15.4.4.9.2 Access Protocol

15.4.4.9.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see Section 15.4.4.13, *NAND Device Basic Programming Model*, and Section 15.4.4.13.1, *NAND Memory Device in Byte or Word 16 Stream Mode*.

15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13:12] DEVICESIZE field (i = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 15.4.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See Section 15.4.4.13, *NAND Device Basic Programming Model*.

15.4.4.9.3 External Signals

15.4.4.9.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The GPMC features three input wait pins: gpmc_wait2, gpmc_wait1 and gpmc_wait0. These pins allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17:16] WAITPINSELECT field (i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

15.4.4.9.3.1.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (i = 0 to 7).

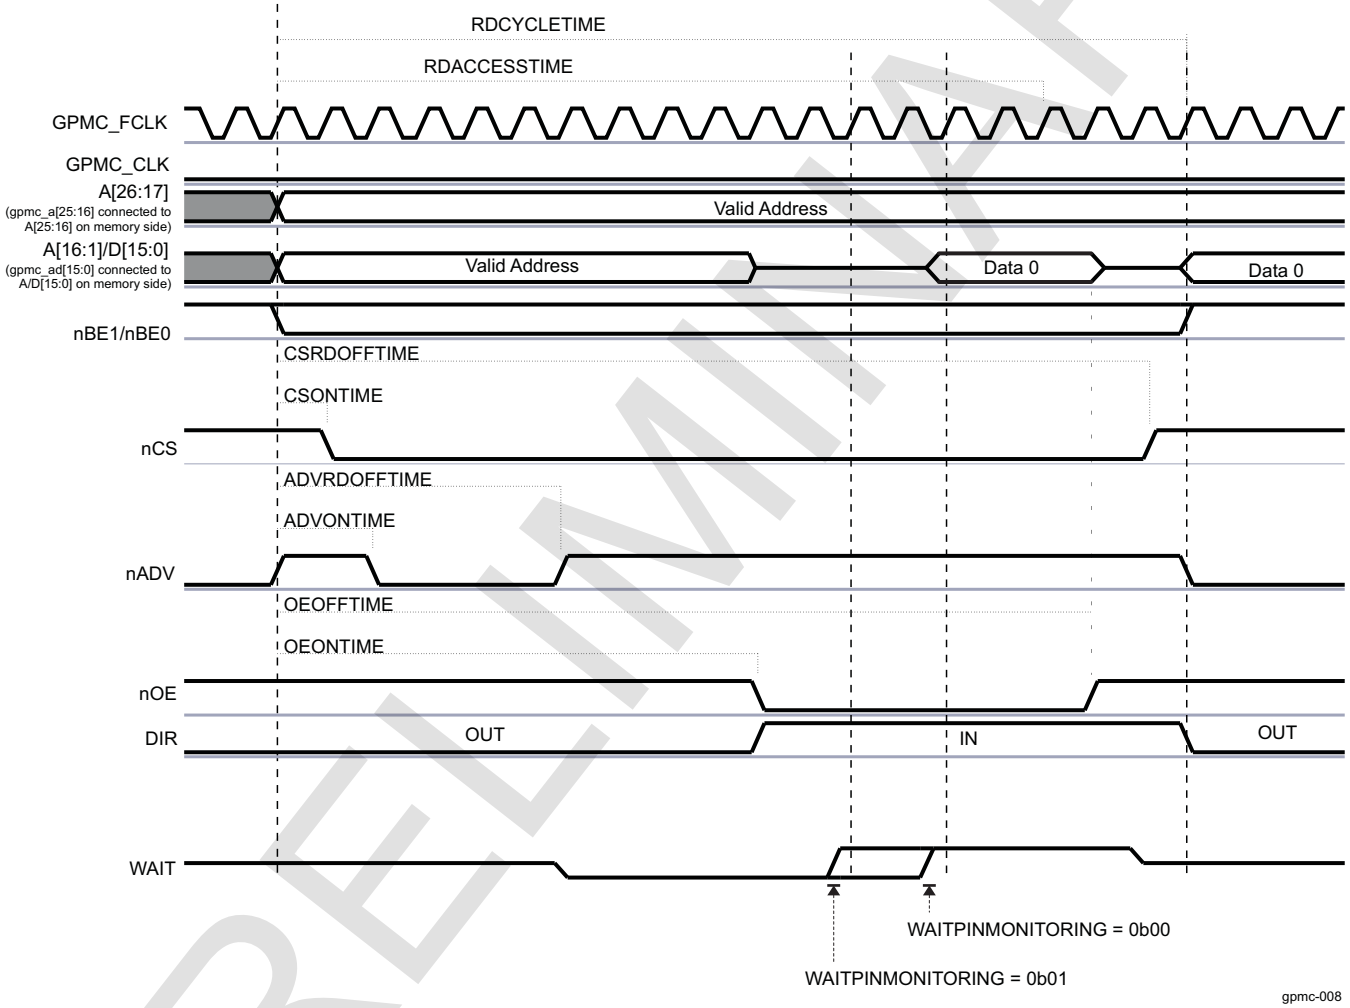
Copyright © 2011, Texas Instruments Incorporated

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-56 shows wait behavior during an asynchronous single read access.

Figure 15-56. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.

15.4.4.9.3.1.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME fields (i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

15.4.4.9.3.1.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

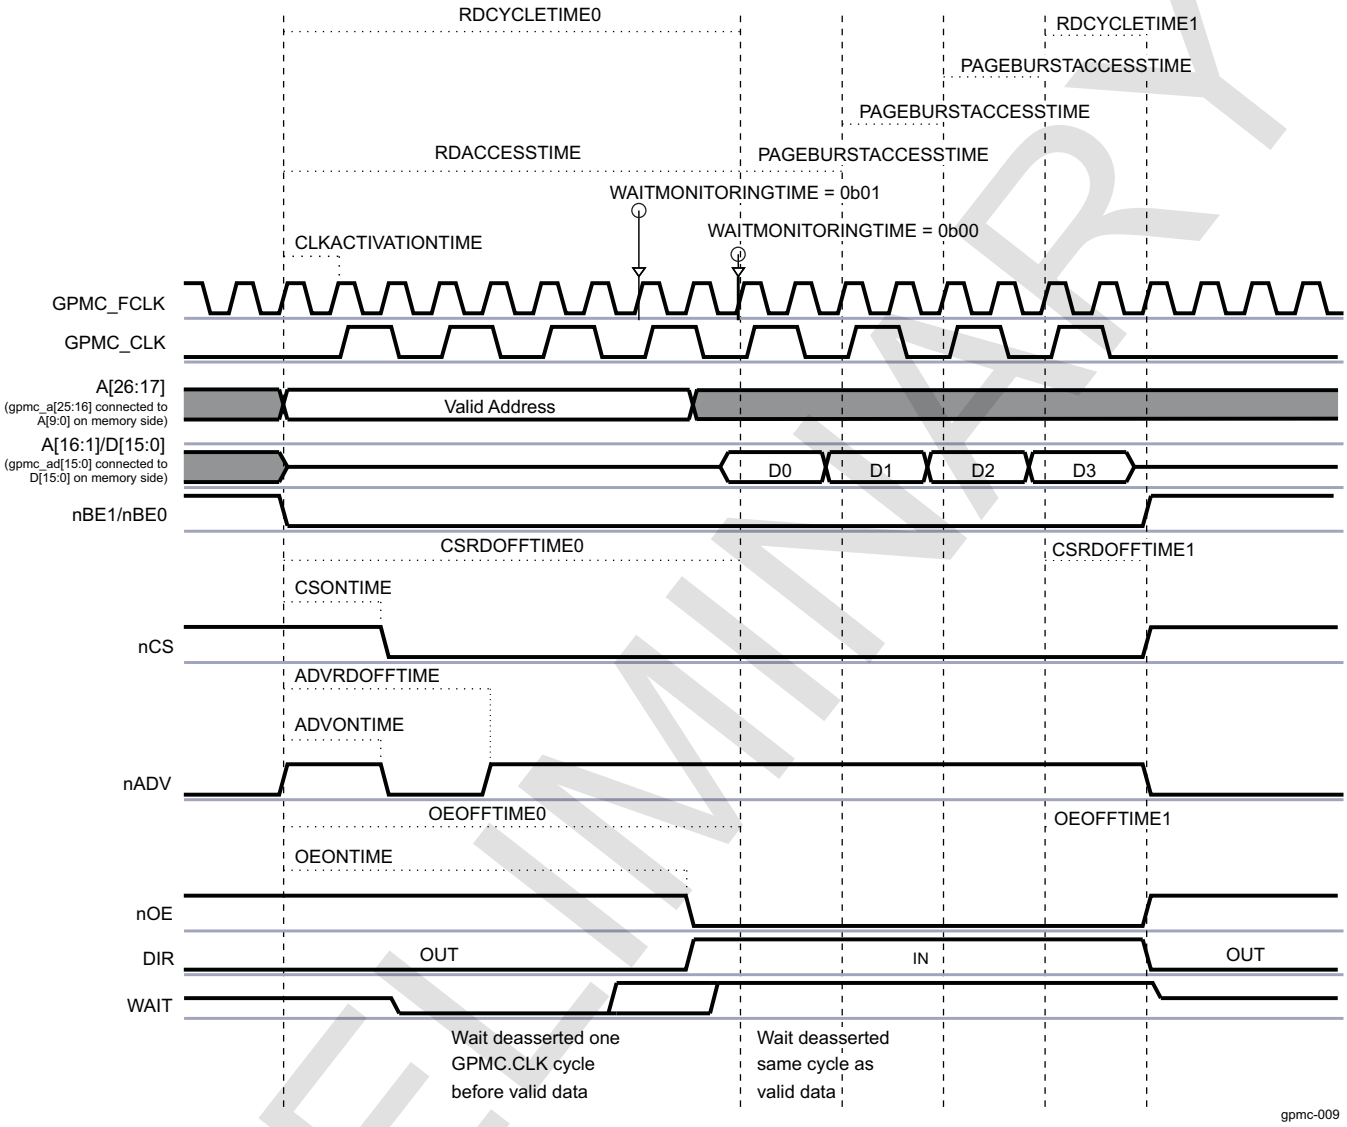
Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Copyright © 2011, Texas Instruments Incorporated

Figure 15-57 shows wait behavior during a synchronous read burst access.

Figure 15-57. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.9.3.1.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

Copyright © 2011, Texas Instruments Incorporated

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

15.4.4.9.3.1.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 15.4.4.13.2, *NAND Device-Ready Pin*.

15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3:0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See Figure 15-58 to Figure 15-60.

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

Copyright © 2011, Texas Instruments Incorporated

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in GPMC_CONFIG6_i registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 15.4.4.9.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)* for more details on bus turnaround.

Table 15-225 describes the configuration required for idle cycle insertion.

Table 15-225. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

PRELIMINARY

15.4.4.9.3.2 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_ad[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see Section 15.4.4.10.10, *Bus Keeping Support*).

In nonmultiplexed devices, the gpmc_io_dir pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit wide devices support is limited to 2 Kbytes).

15.4.4.9.3.3 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

15.4.4.9.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

15.4.4.9.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.9.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.10 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see Section 15.4.4.10.6, *GPMC_CLK*.

NOTE: In the following sections, the start access time refer to the time at which the access begins.

15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC_CONFIG5_i[12:8] WRCYCLETIME fields (i = 0 to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

Copyright © 2011, Texas Instruments Incorporated

15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3:0] CSONTIME field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

GPMC_CONFIG2_i[12:8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20:16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

GPMC_CONFIG3_i[12:8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20:16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

Copyright © 2011, Texas Instruments Incorporated

See Section 15.4.4.13, *NAND Access Description* for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

15.4.4.10.4 nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3:0] OEONTIME field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i[12:8] OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses. nOE/nRE is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.10.5 nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. These bit fields only apply to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Copyright © 2011, Texas Instruments Incorporated

15.4.4.10.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

15.4.4.10.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME (i = 0 to 7). This allows nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

15.4.4.10.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i[20:16] RDACCESSTIME field (i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4:0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 15.4.4.9.3.1, *Chip-Select Base Address and Region Size*.

15.4.4.10.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 15.4.4.9.3.1, *Chip-Select Base Address and Region Size*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 15.4.4.9.3.1, *Chip-Select Base Address and Region Size*.

15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (i = 0 to 7) can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

15.4.4.10.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 15.4.4.9.3.1, *Chip-Select Base Address and Region Size*.

15.4.4.10.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 15.4.4.9.3.1, *Chip-Select Base Address and Region Size*.

15.4.4.10.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

Copyright © 2011, Texas Instruments Incorporated

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (i = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

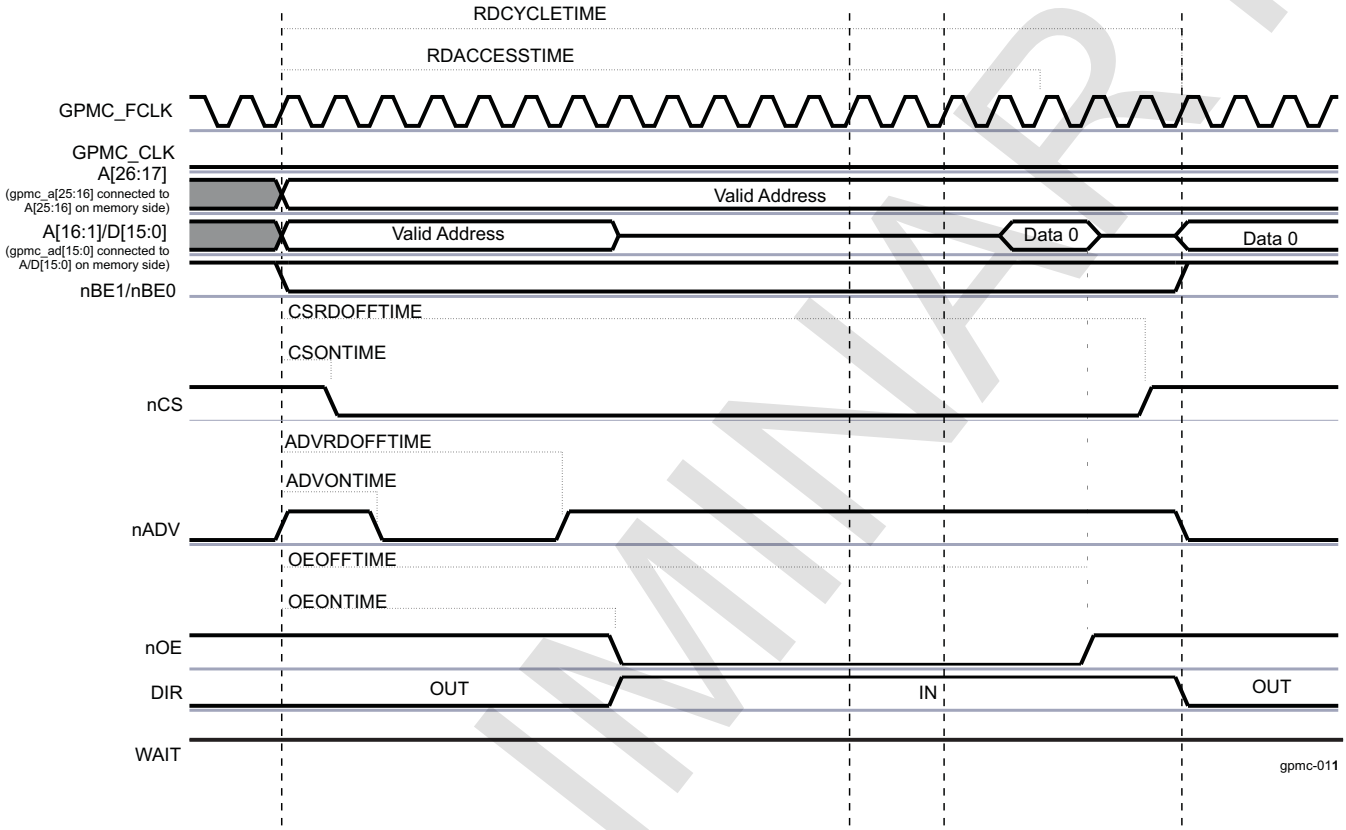
15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-61 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-61. Asynchronous Single Read on an Address/Data-Multiplexed Device



See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-257 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

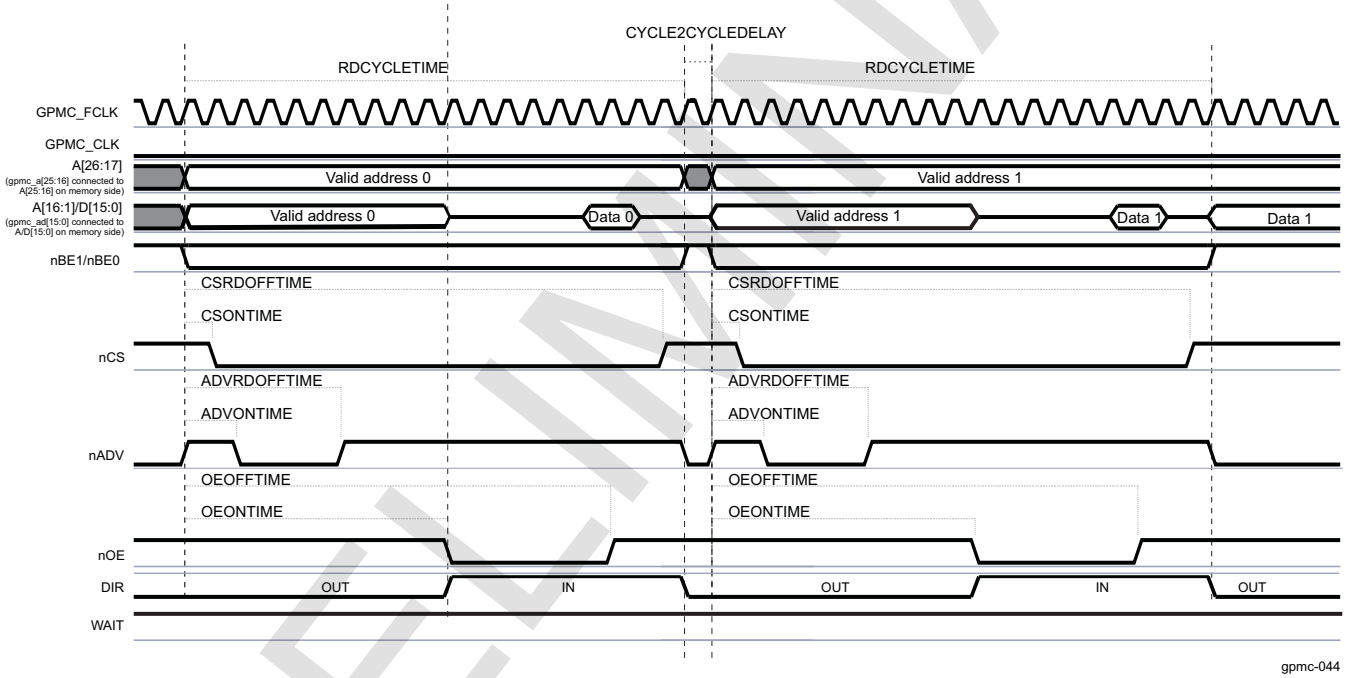
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 15.4.4.11.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 15-62. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-bit read split into 2 x 16-bit read)



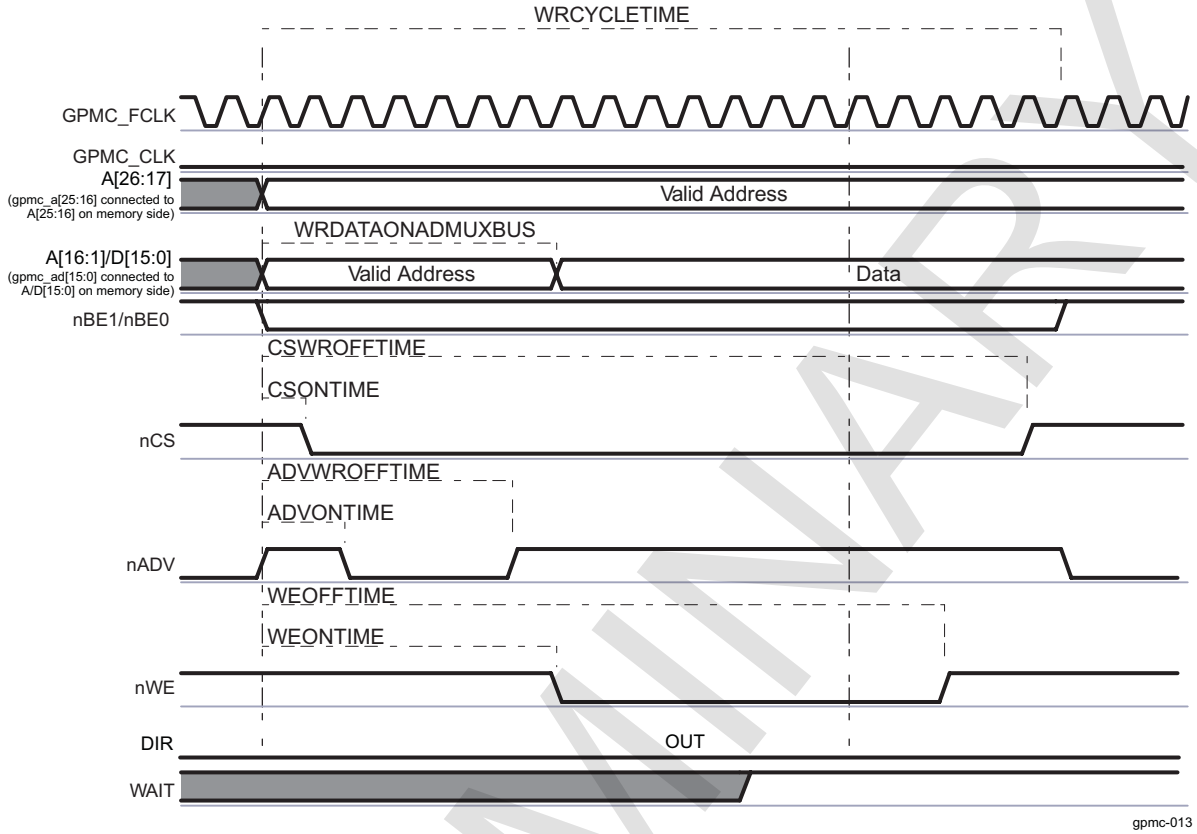
15.4.4.11.1.1.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 15-63 shows an asynchronous single write operation on an address/data-multiplexed device.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-63. Asynchronous Single Write on an Address/Data-Multiplexed Device



See Section 15.4.5.6.1, *GPMC Timing Parameterss Formulas* for formulas to calculate timing parameters.

Table 15-257 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

The nCS, and nADV signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

Copyright © 2011, Texas Instruments Incorporated

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (0x1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices refer to Section 15.4.4.11.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

PRELIMINARY

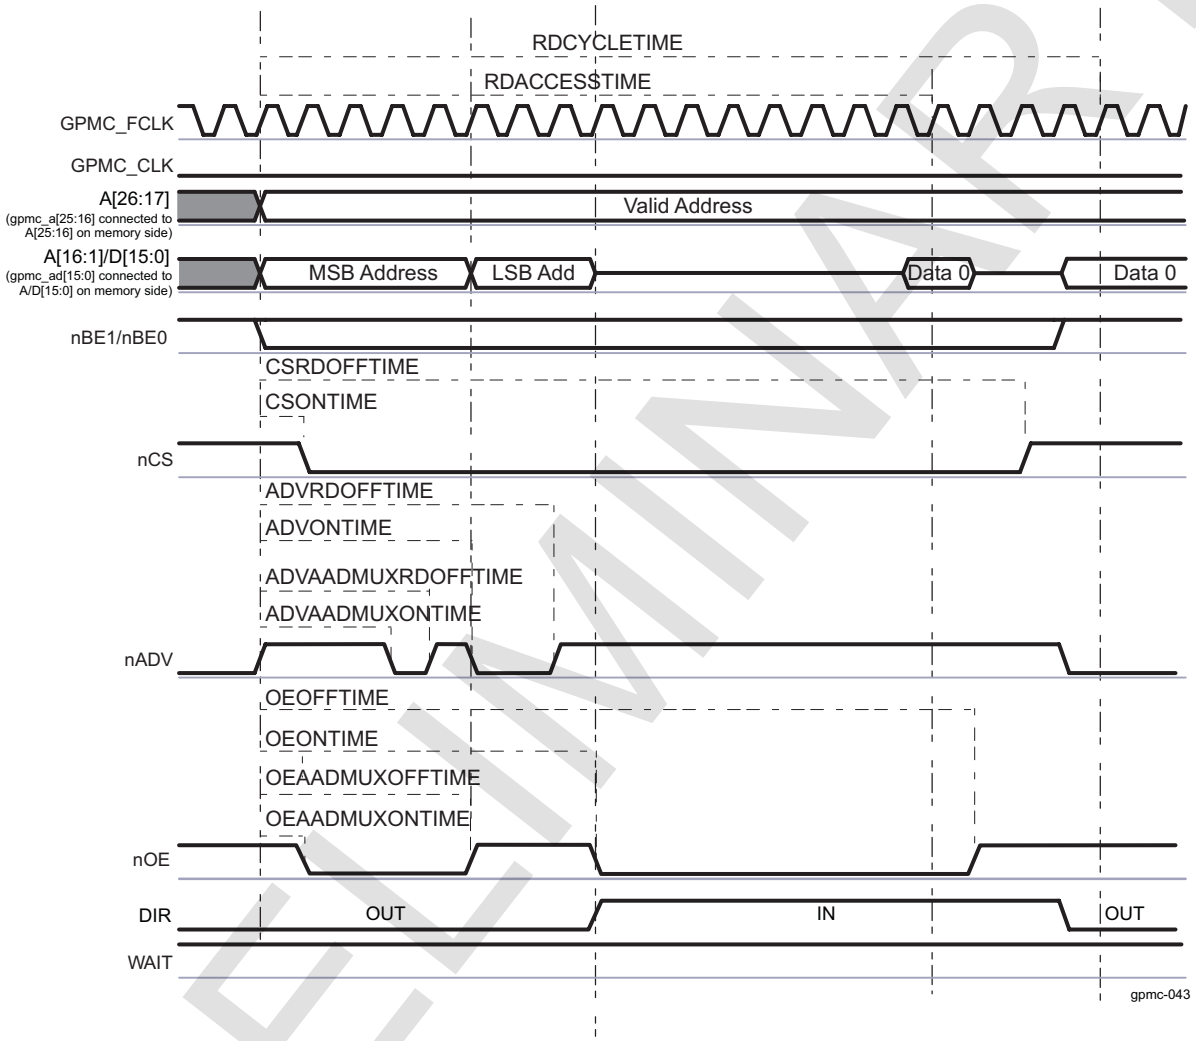
15.4.4.11.1.2 Access on Address/Address/Data Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-64 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 15-64. Asynchronous Single Read on an AAD-Multiplexed Device



See Section 15.4.5.6.1, *GPMC Timing Parameterss Formulas* for formulas to calculate timing parameters.

Table 15-257 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS, and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME field.

Copyright © 2011, Texas Instruments Incorporated

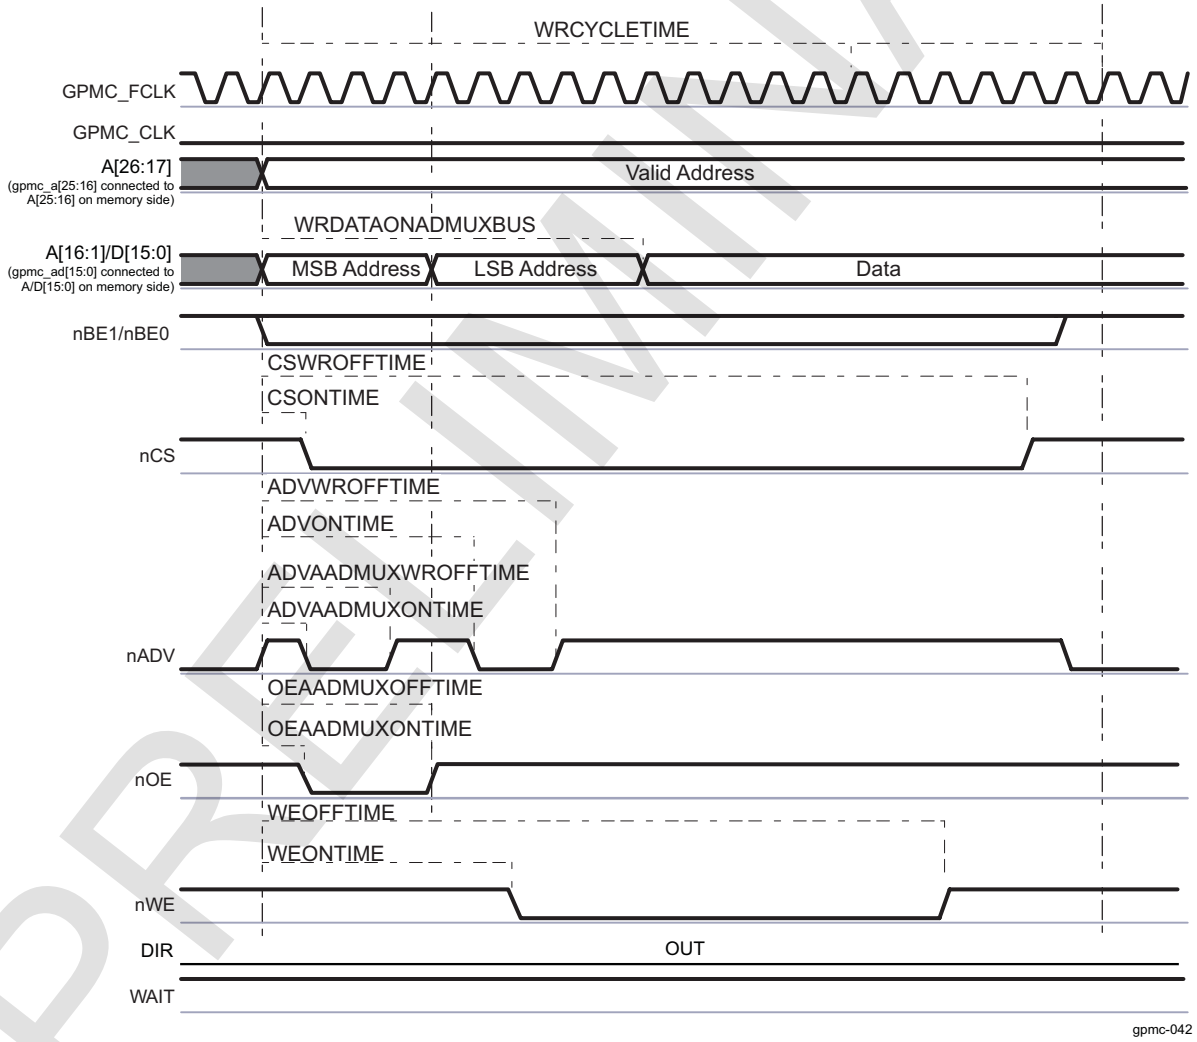
PRELIMINARY

  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.

15.4.4.11.1.2.2 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 15-65. Asynchronous Single Write on an AAD-Multiplexed Device



See Section 15.4.5.6.1, *GPMC Timing Parameterss Formulas* for formulas to calculate timing parameters.

Table 15-257 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

Copyright © 2011, Texas Instruments Incorporated

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device. See Table 15-248.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.
- Output Enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (0x1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices refer to Section 15.4.4.11.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.11.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices refer to Section 15.4.4.11.3, *Asynchronus and Synchronus Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

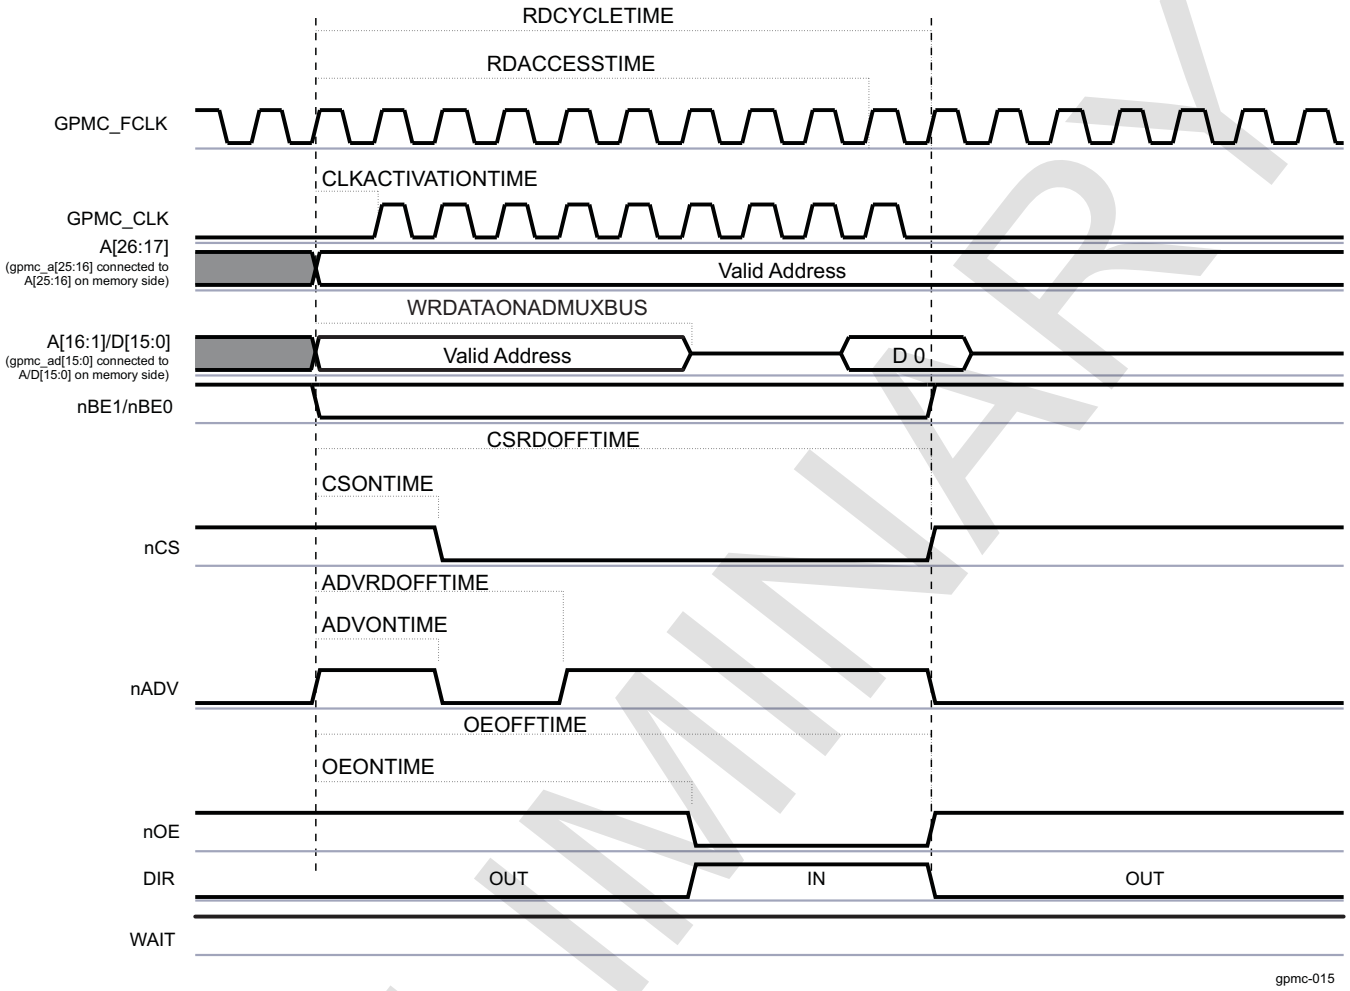
15.4.4.11.2.1 Synchronous Single Read

Figure 15-66 and Figure 15-67 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

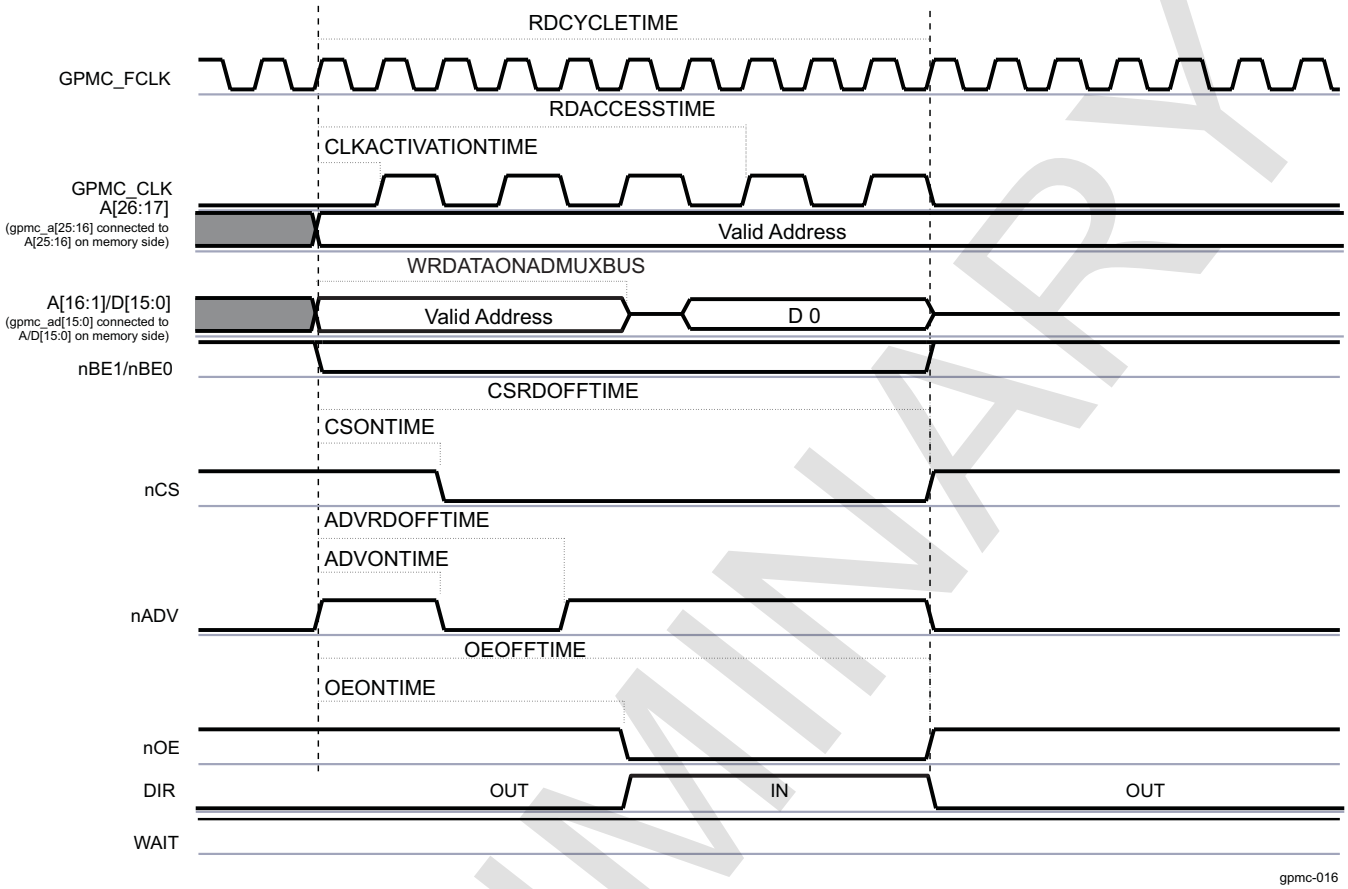
Figure 15-66. Synchronous Single Read (GPMCFCLKDIVIDER = 0)



PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-67. Synchronous Single Read (GPMCFCLKDIVIDER = 1)



See Section 15.4.5.6.1, *GPMC Timing Parameterss Formulas* for formulas to calculate timing parameters.

Table 15-257 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

Copyright © 2011, Texas Instruments Incorporated

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 15-68 and Figure 15-69 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

PRELIMINARY

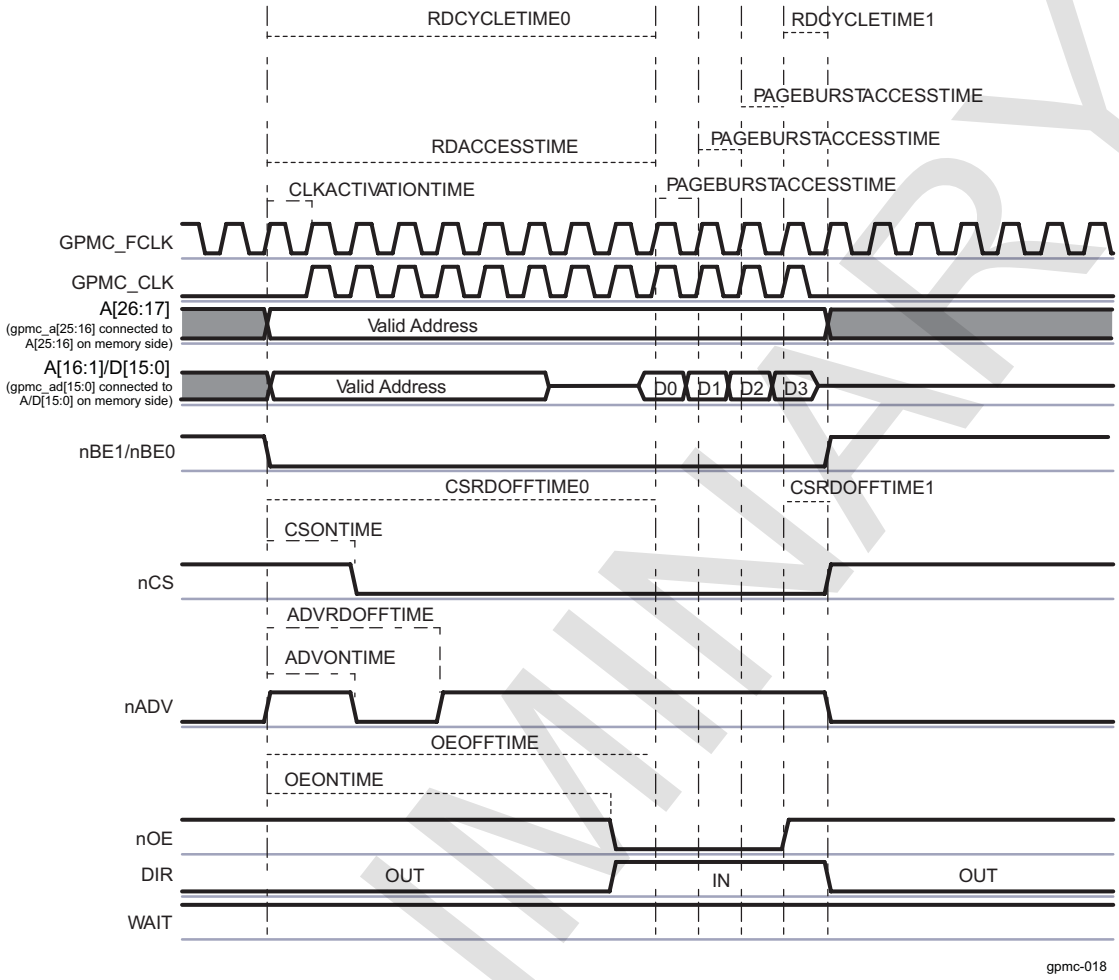
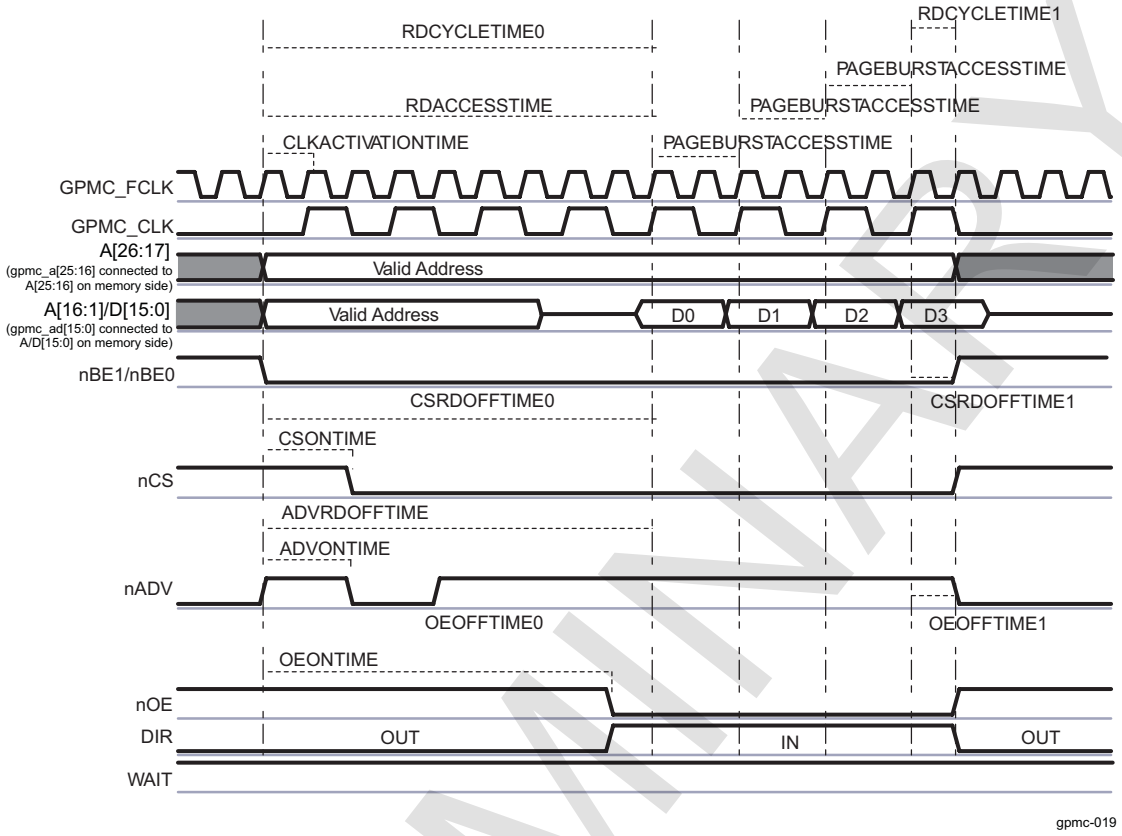
Figure 15-68. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)



PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)



When GPMC_CONFIG5_i[20:16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The nCS, nADV, nOE and DIR signals are controlled in the same way as for synchronous single read operation. See Table 15-243.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-69, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH.

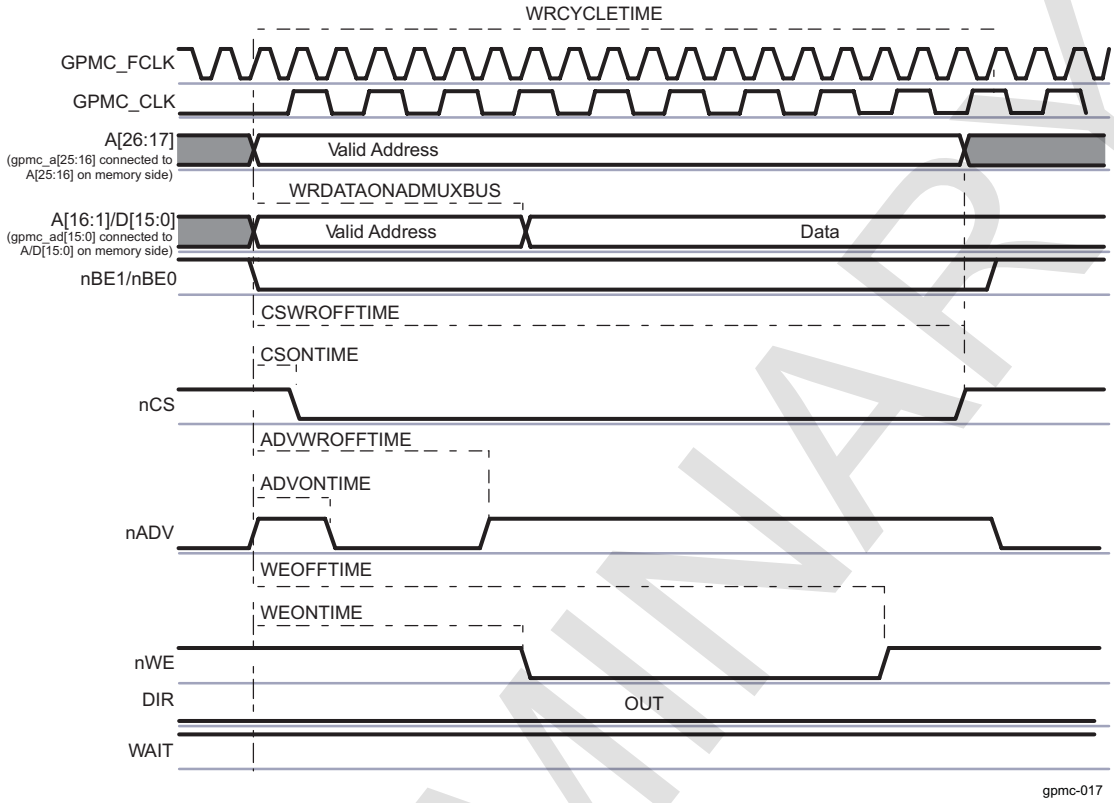
15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-70. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-71 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-71. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

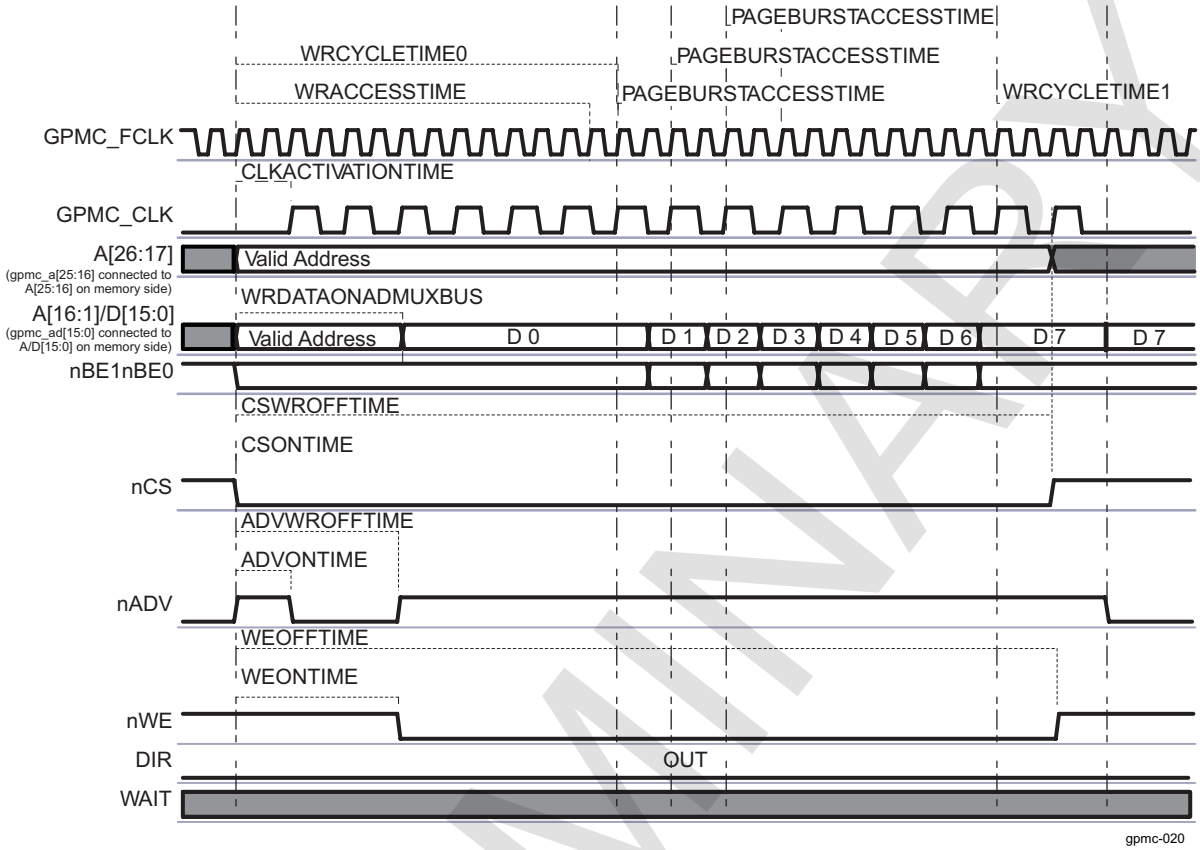


Figure 15-72 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

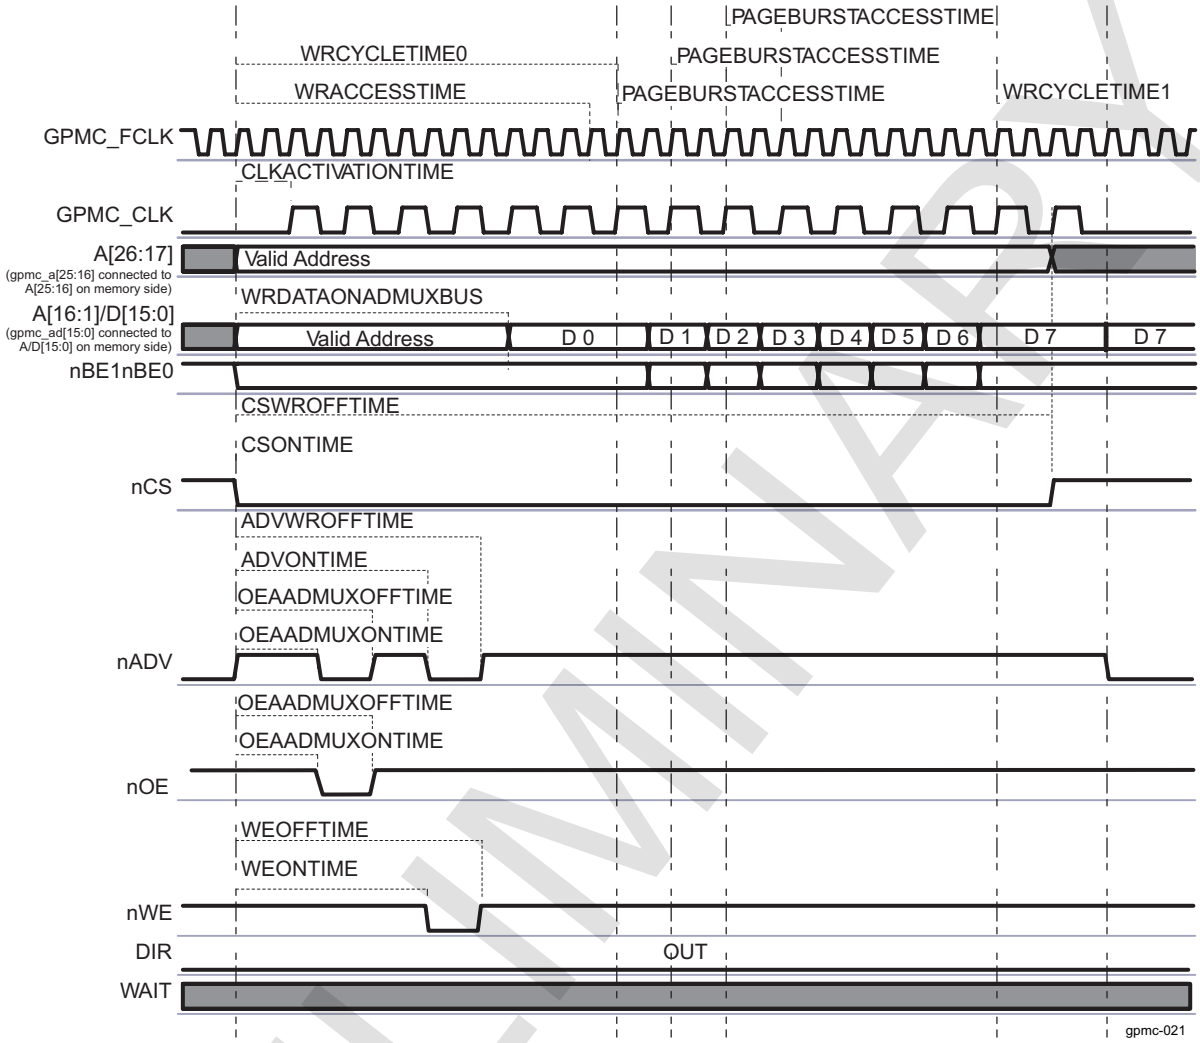
PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME field (i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME field.

Copyright © 2011, Texas Instruments Incorporated

– nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the nWE signal at low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as detailled above.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-71, the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-muxed mode. The non-muxed mode is described in this section even though its use is very limited (address space limited to 2 KBytes).

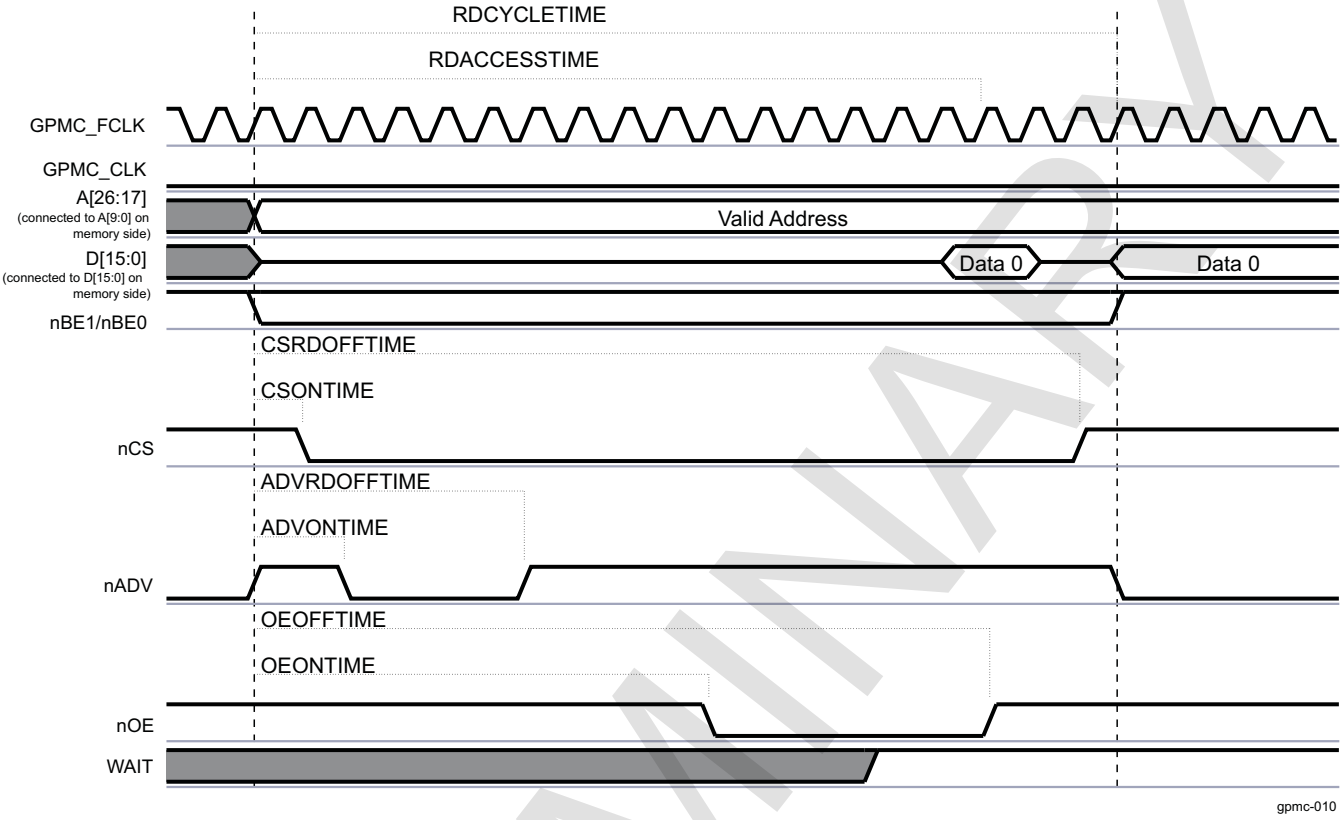
- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 15-73 shows an asynchronous single read operation on a nonmultiplexed device.

Copyright © 2011, Texas Instruments Incorporated

Figure 15-73. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see Table 15-248.

15.4.4.11.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 15-74 shows an asynchronous single write operation on a nonmultiplexed device.

PRELIMINARY

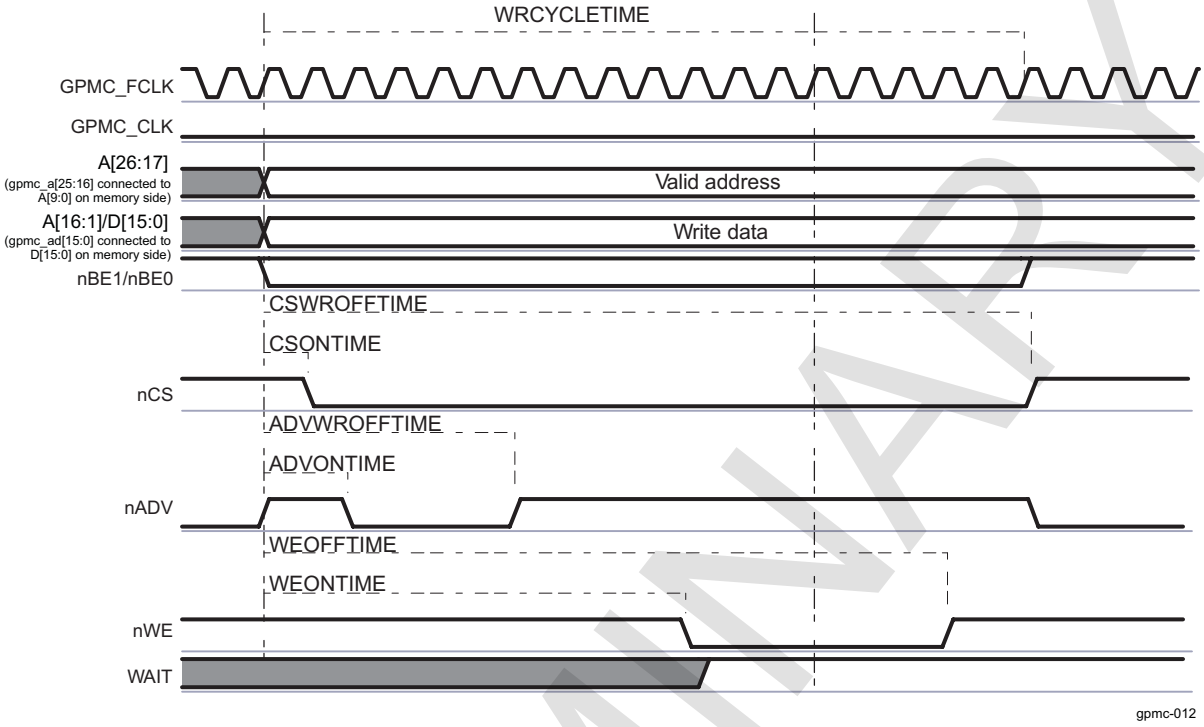
Figure 15-74. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nWE and DIR signals are controlled in the same way as address/data multiplexed accesses, see Table 15-248.

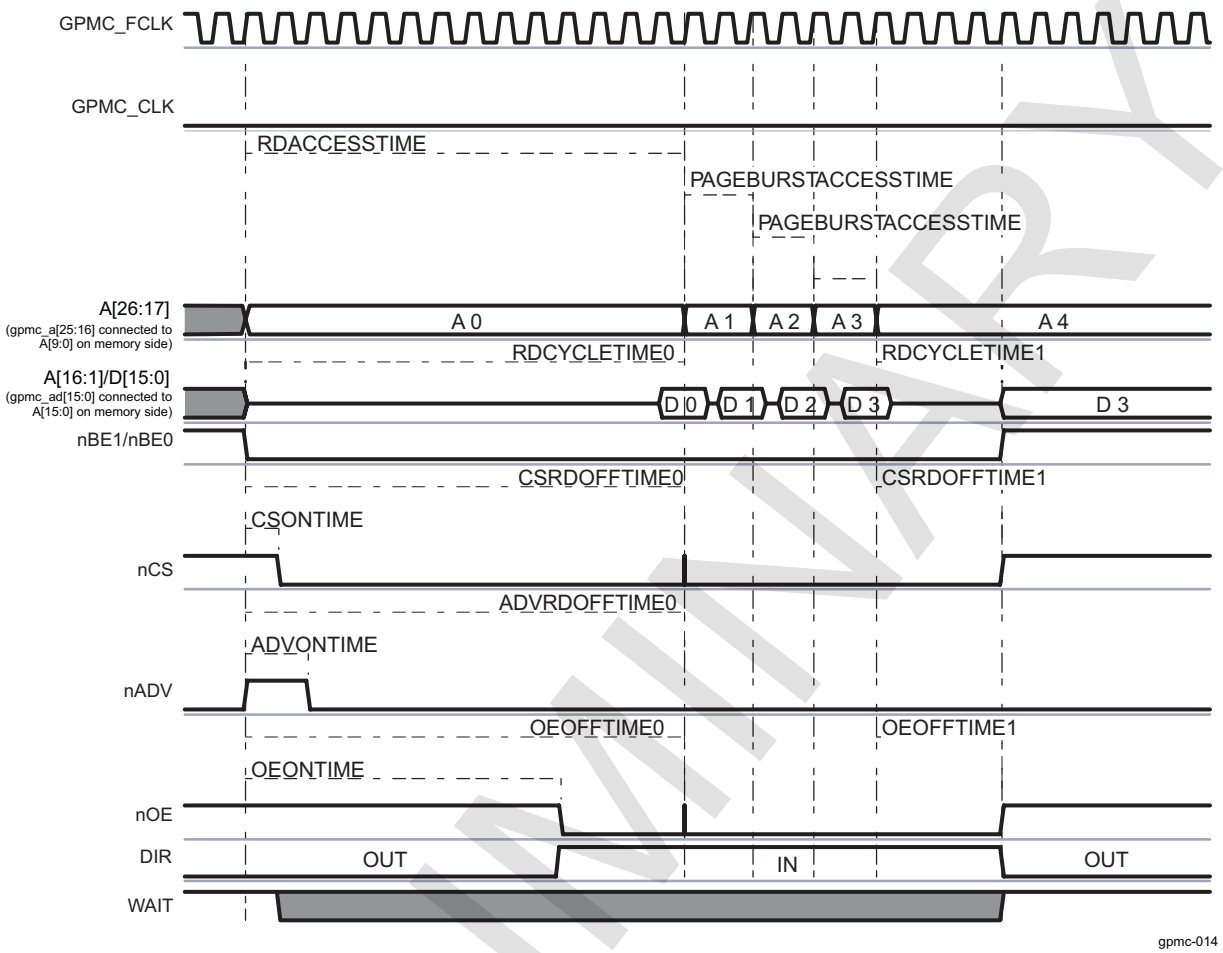
15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 15-75 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-75. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see Table 15-248.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
- In Figure 15-75, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

PRELIMINARY

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 15.4.5.3, *GPMC Configuration in NOR Mode*.

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

15.4.4.11.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field (i = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

Copyright © 2011, Texas Instruments Incorporated

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

NOTE: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE field (i = 0 to 7) must be set to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices since the chip-select allocated to the NAND device has to be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 15-226. Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-226. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode

(1) i = 0 to 7

PRELIMINARY

Table 15-226. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i register location and to the GPMC_NAND_ADDRESS_i register location must be posted for faster operations (i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (i = 0 to 7) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (i = 0 to 7) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

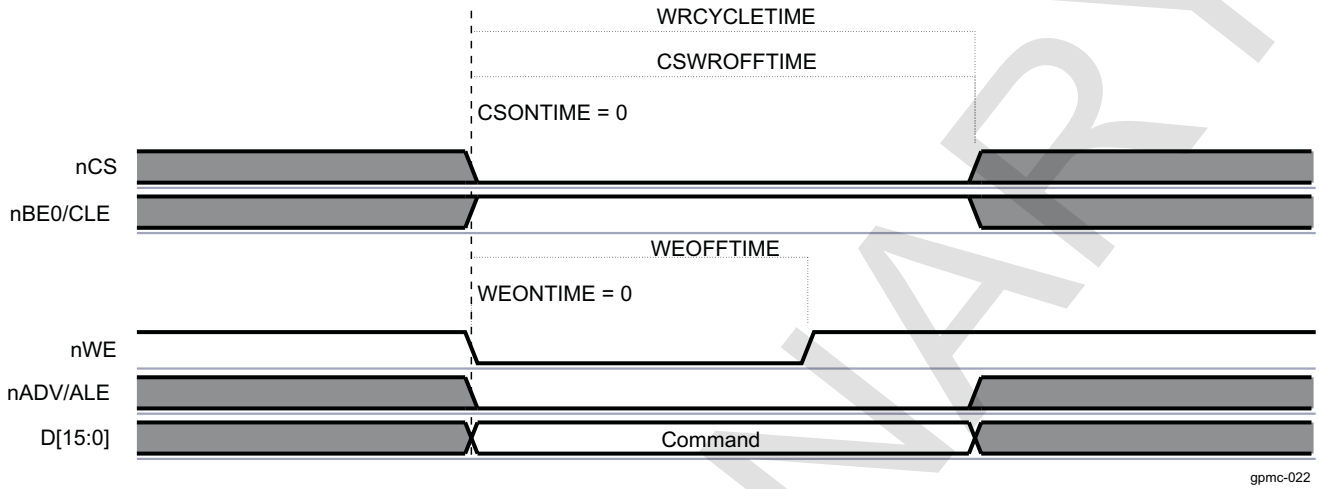
Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 15-76 shows the NAND command latch cycle.

Figure 15-76. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

15.4.4.13.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

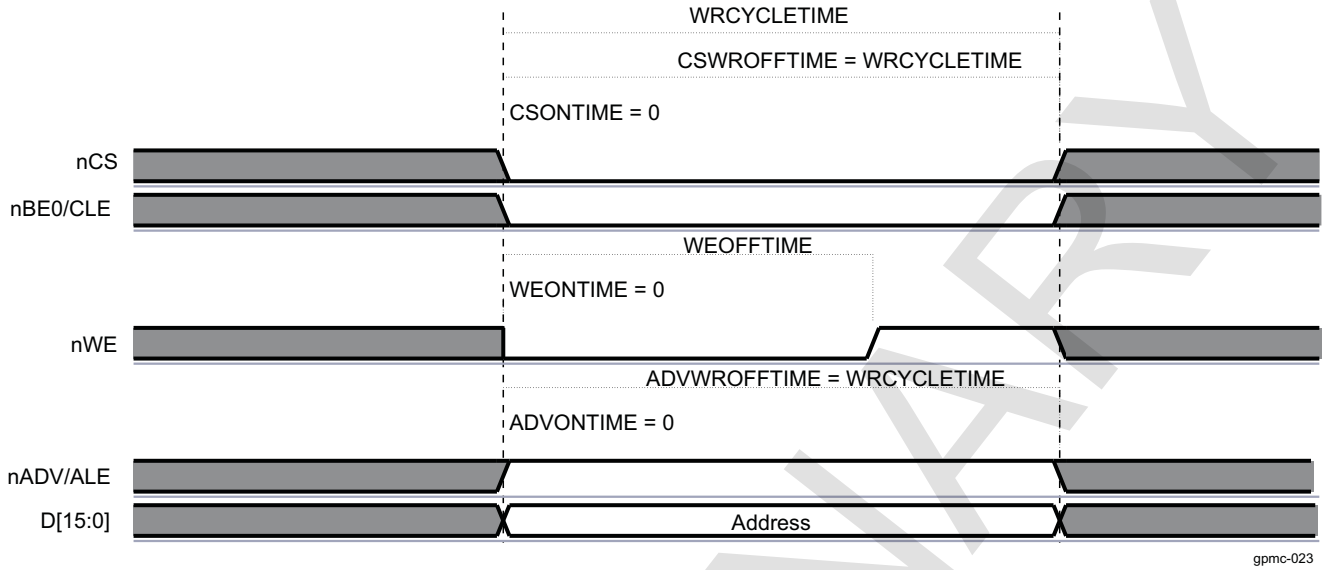
- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND address latch cycle.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 15-77. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-78 shows the NAND data read cycle.

PRELIMINARY

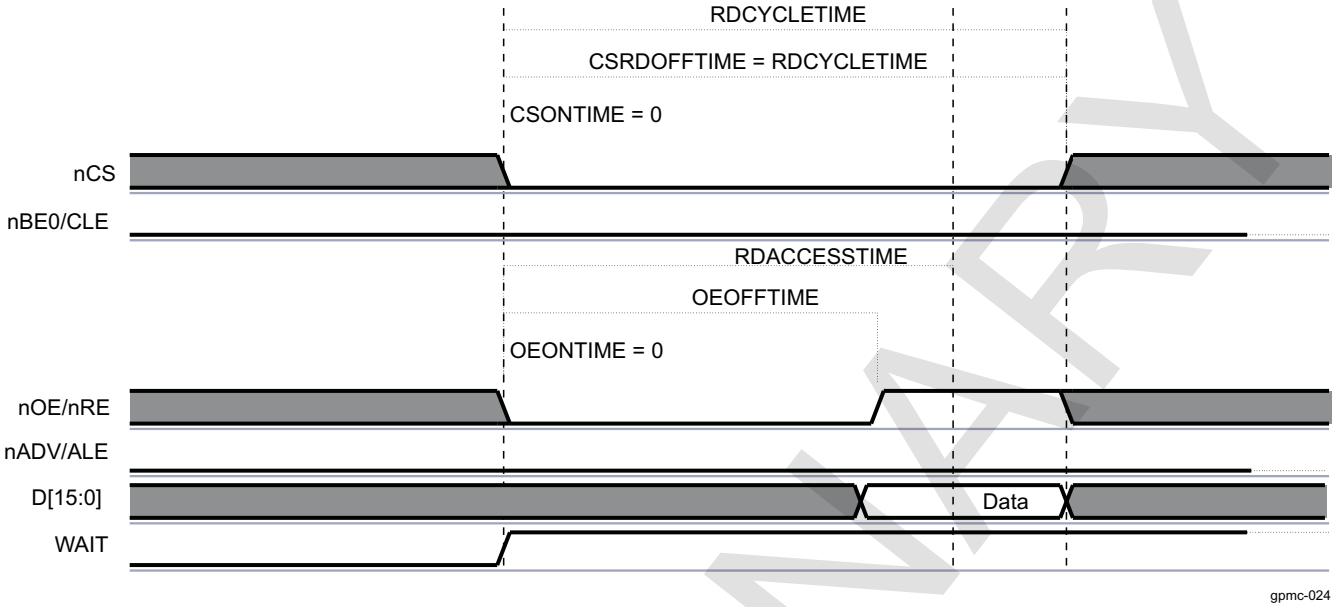
Figure 15-78. NAND Data Read Cycle

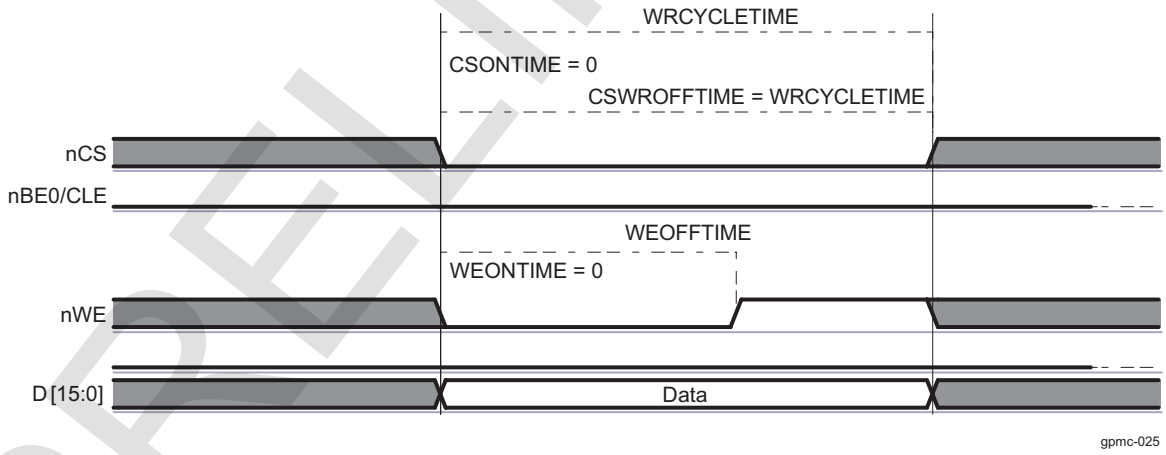


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-79 shows the NAND data write cycle.

Figure 15-79. NAND Data Write Cycle



15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce

Copyright © 2011, Texas Instruments Incorporated

RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see Section 15.4.4.13.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-bit wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

15.4.4.13.1.7.2 16-bit wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Copyright © 2011, Texas Instruments Incorporated

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 3) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (x = 0 or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (x = 0 or 3) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
2. BCH (Bose-Chaudhurl-Hocquenghem) code for 4- to 16-bit error correction

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC_ECCj_RESULT register value (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

Copyright © 2011, Texas Instruments Incorporated

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 15-227 describes the ECC enable settings.

Table 15-227. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 15-80 and Figure 15-81. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

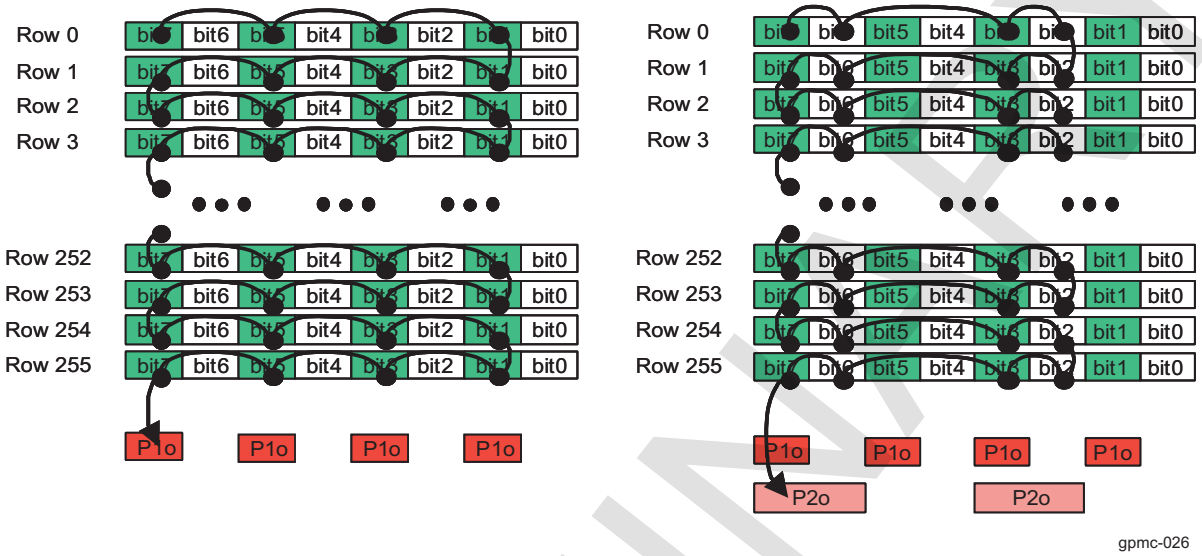
P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

Copyright © 2011, Texas Instruments Incorporated

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 15-80. Hamming Code Accumulation Algorithm (1/2)

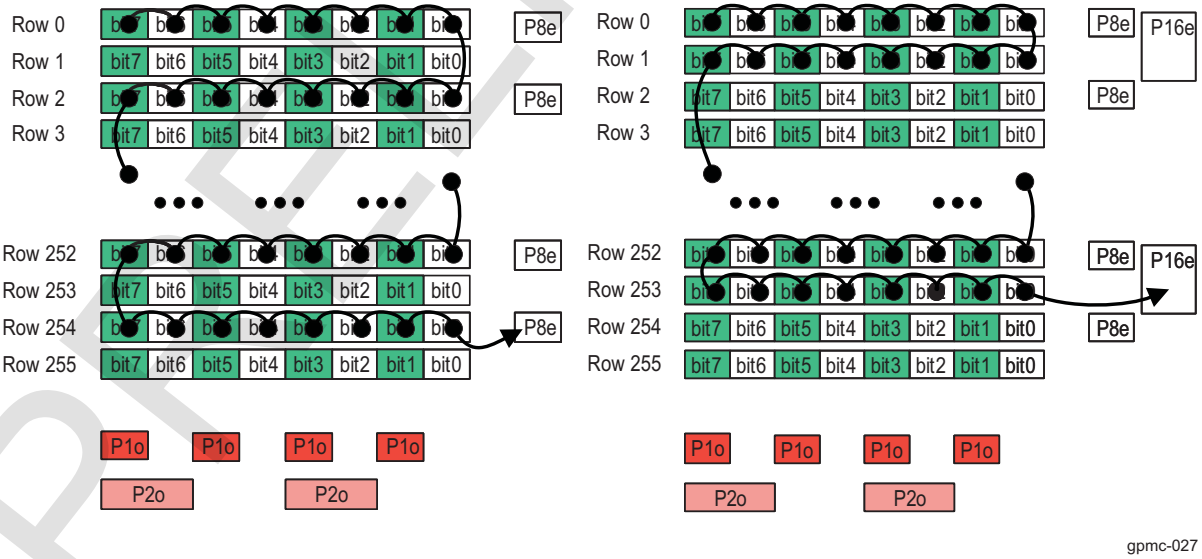


For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 15-81. Hamming Code Accumulation Algorithm (2/2)



Unused parity bits in the result registers are set to 0.

Figure 15-82 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Copyright © 2011, Texas Instruments Incorporated

Figure 15-82. ECC Computation for a 256-Byte Data Stream (Read or Write)

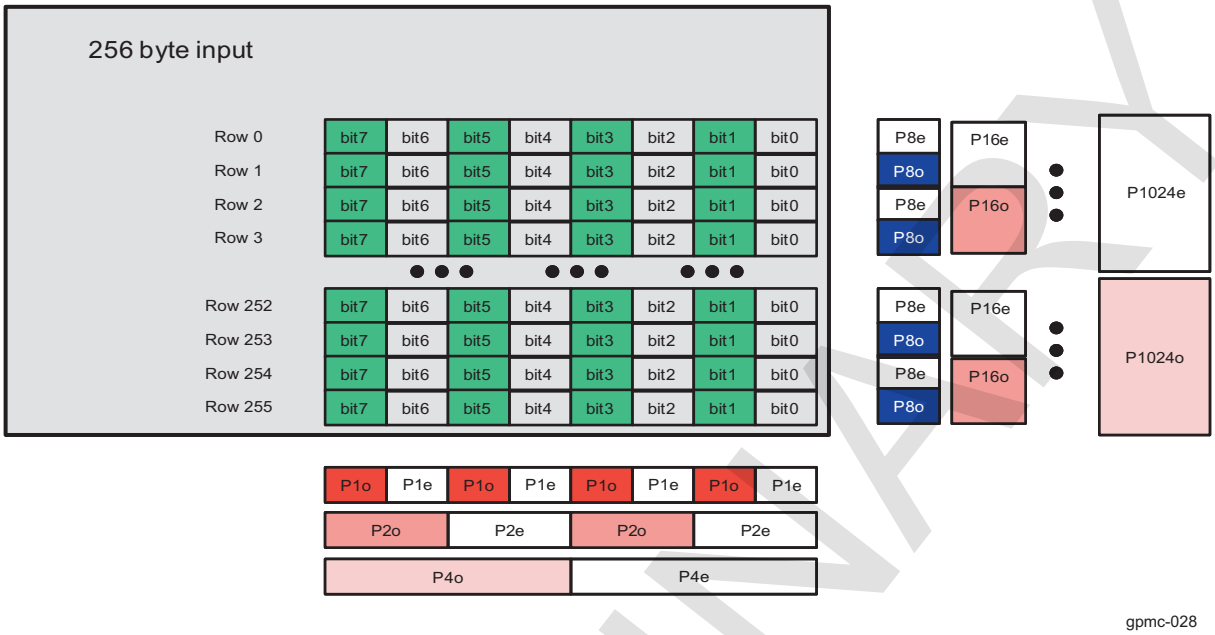


Figure 15-83 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

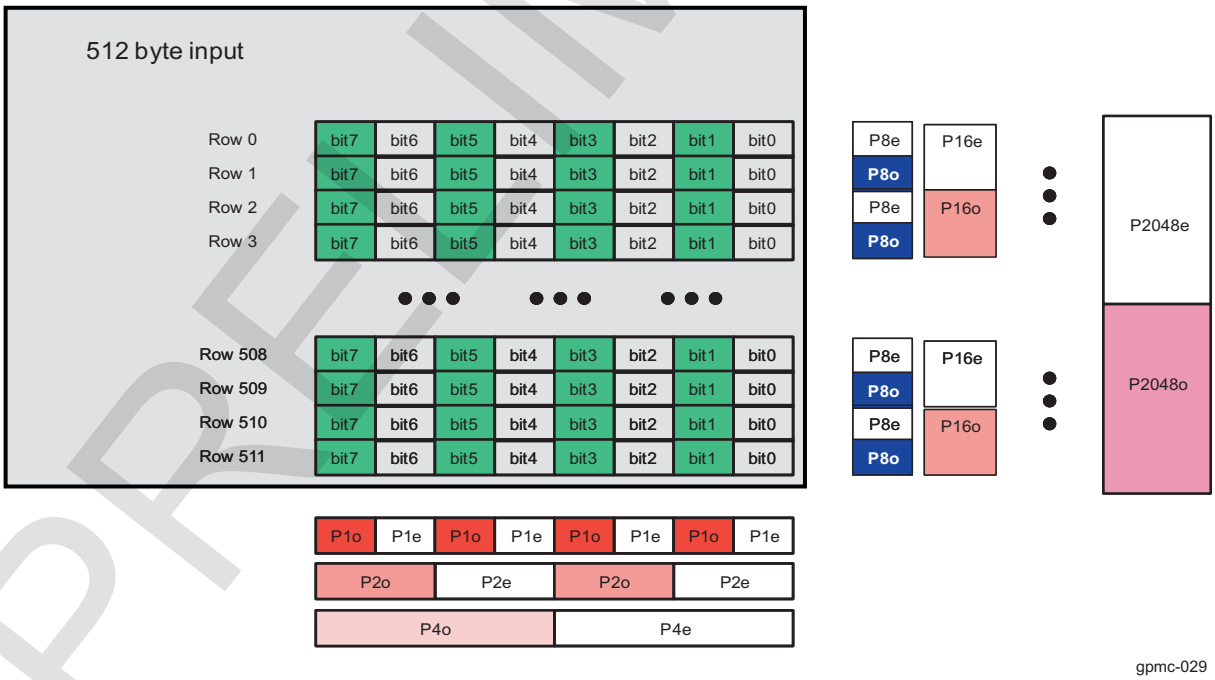
Figure 15-83. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

Copyright © 2011, Texas Instruments Incorporated

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 15-84 and Figure 15-85 show a 128 Word 16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

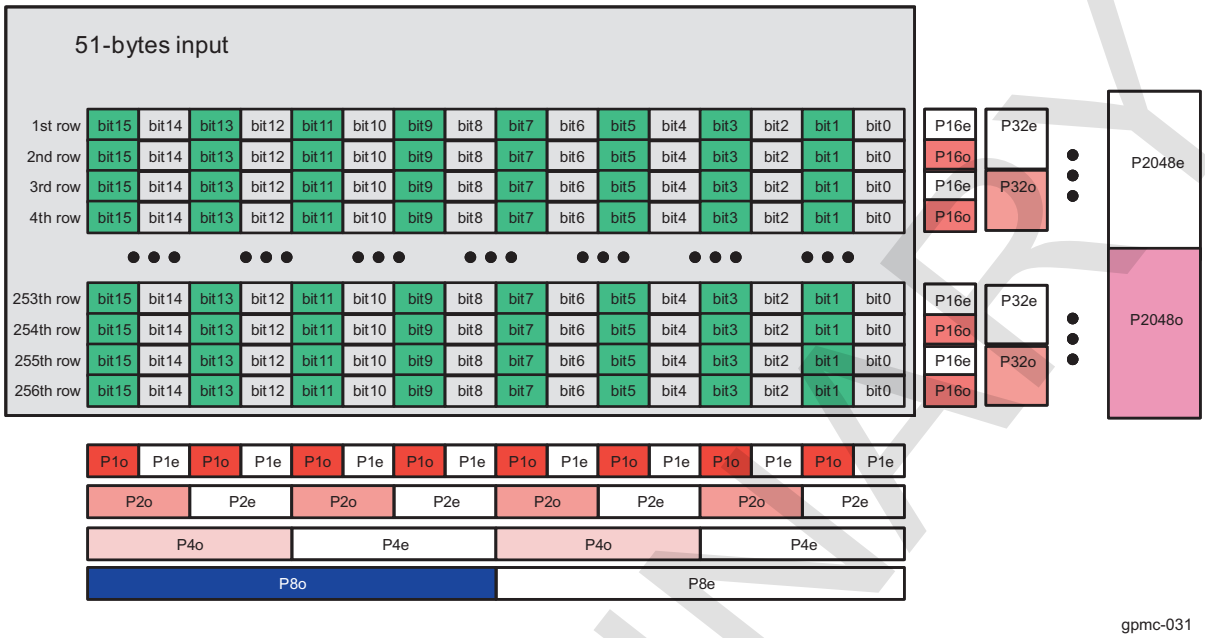
Figure 15-85. 256 Word16 ECC Computation



15.4.4.13.3.2 BCH Code (Bose-Chaudhurl-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.
   Typical page write sequence:
   - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
   - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
   - NAND writes its cache line (page) to the array.

   Typical page read sequence:
   - Sequential read of a page. ECC is calculated on the fly.
   - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
   The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4

Copyright © 2011, Texas Instruments Incorporated

cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.

5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

15.4.4.13.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree 2^{12} - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 15-228.

Table 15-228. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) * 8) - 1 = 4119, for a total of 3+13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in GPMC_BCH_RESULT0_i, GPMC_BCH_RESULT1_i, GPMC_BCH_RESULT2_i, and GPMC_BCH_RESULT3_i (where i = 0 to 7).

15.4.4.13.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 * $x^{(7+i)}$ + b6 * $x^{(6+i)}$ + ... + b0 * x^{i}
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^{12}-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

...	...	...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 15.4.4.13.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

Copyright © 2011, Texas Instruments Incorporated

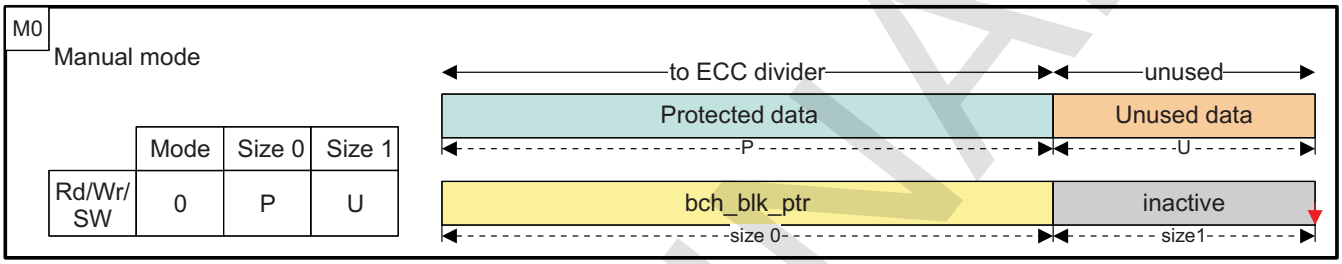
15.4.4.13.3.2.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

NOTE: In the following figures size and size0 are the same parameter.

Figure 15-86. Manual Mode Sequence and Mapping



Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 15.4.4.13.3.2.2.1, *Memory-Mapping of the Data Message*.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 15-87 to Figure 15-89, tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

Copyright © 2011, Texas Instruments Incorporated

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC_NAND_COMMAND_i, GPMC_NAND_ADDRESS_i, and GPMC_NAND_DATA_i registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 15.4.4.13.2.2, *Ready Pin Monitored by Hardware Interrupt*. The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT field.

Table 15-237. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.

Table 15-237. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the

Copyright © 2011, Texas Instruments Incorporated

programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is trigerred. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-238. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode

PRELIMINARY

Table 15-238. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

Copyright © 2011, Texas Instruments Incorporated

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

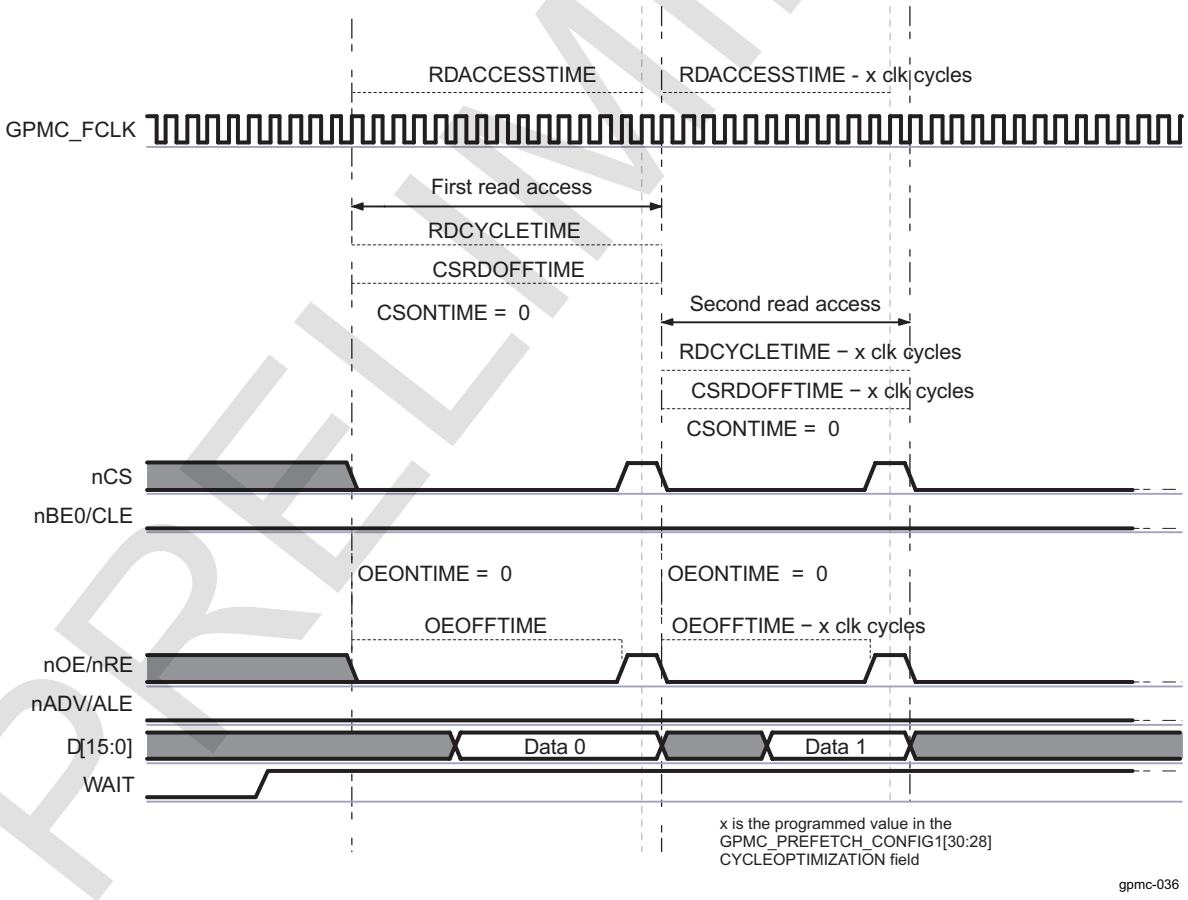
15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 15-90 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 15-90. NAND Read Cycle Optimization Timing Description



15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an

Copyright © 2011, Texas Instruments Incorporated

access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finnaly back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top down approach to users that need to configure the GPMC module.

Figure 15-91, Table 15-239, Table 15-240 and Table 15-241 show a programming model top level diagram for the GPMC, and the description of each step. Each block of the diagram is detailled in one of the following subsections through a set of registers to configure.

15.4.5.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 15-258 details NAND timing parameters.

Table 15-258. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_nwe valid time
B	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time - gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time - gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time - gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time - gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time - gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time - gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration - gpmc_noe valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEExtraDelay)) * GPMC_FCLK period

K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

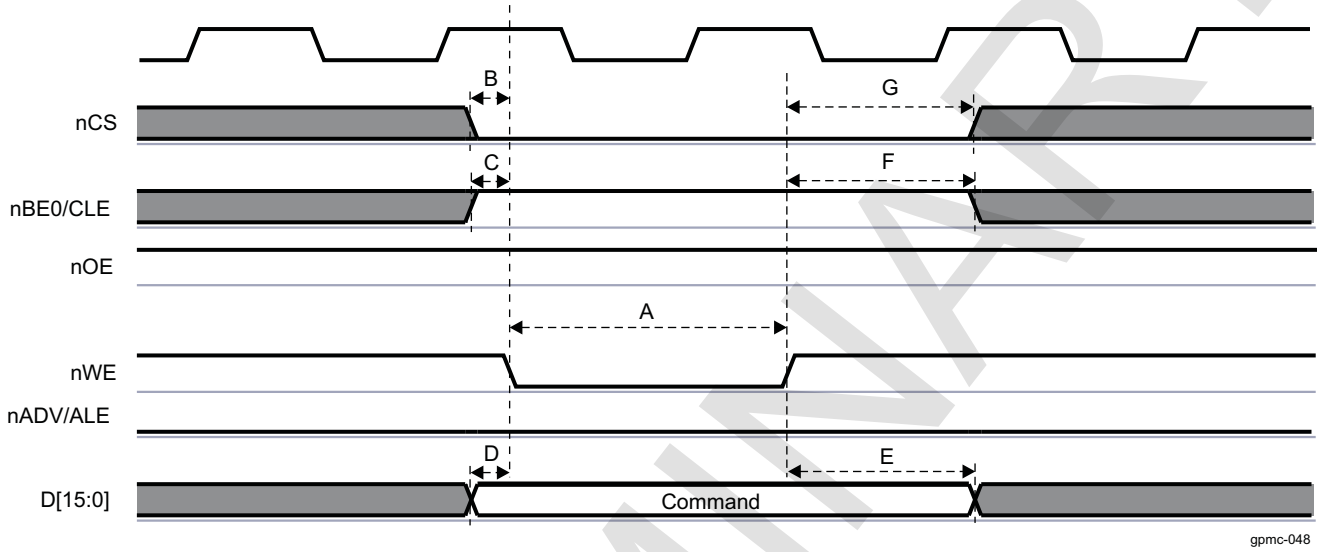
Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 15-93 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 15-93. NAND Command Latch Cycle Timing Simplified Example



15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 15-259. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - address bus valid to gpmc_clk first edge
		Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid
		Delay time - gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time - gpmc_clk rising edge to gpmc_ncs invalid
		Delay time - gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time - gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time - gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time - gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time - gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time - gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration - gpmc_nadv_ale low
L	ns	Delay time - gpmc_wait invalid to first data latching gpmc_clk edge

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
   A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME - ACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME - ACCESSTIME) * GPMC_FCLK period
2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSWROFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (CS activated):
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

   For nCS rising edge (CS desactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

   For nCS rising edge (CS desactivated) in writing mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV desactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV desactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

PRELIMINARY

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nOE rising edge (nOE desactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nWE rising edge (nWE desactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For gpmc_nadv low pulse duration:

- Read operation:
  K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For gpmc_wait invalid to first data latching gpmc_clk edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK

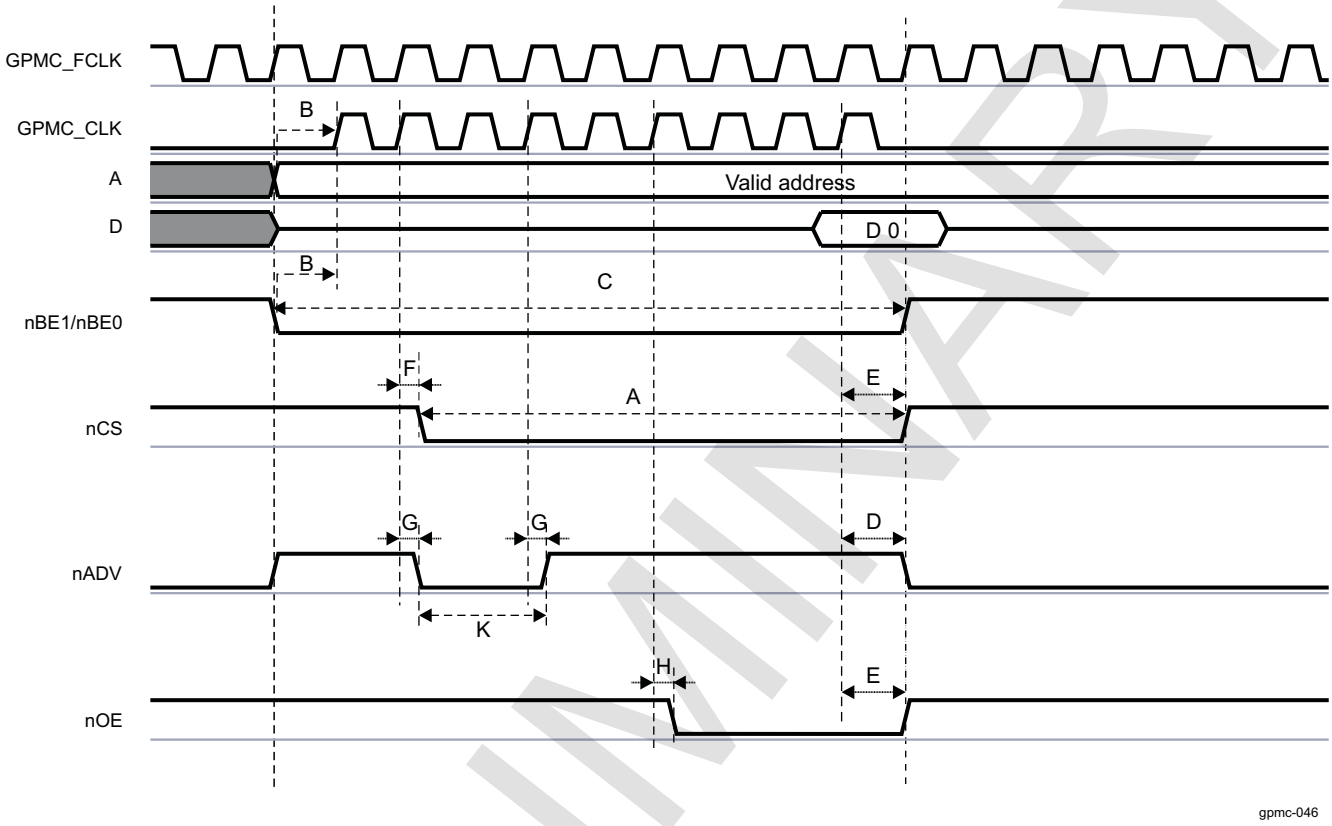
Figure 15-94 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

Figure 15-94. Synchronous NOR Single Read Simplified Example



15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 15-260. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time - gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before gpmc_noe high
I	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (burst read)
J	ns	Delay time - address bus valid to gpmc_ncs valid
		Delay time - data bus valid to gpmc_ncs valid
		Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

Table 15-260. Asynchronous NOR Formulas Description Table (continued)

Configuration Parameter	Unit	Description
L	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time - gpmc_ncs valid to first data latching edge
N	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 valid time
O	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

- gpmc_ncs low pulse:
  For single read: A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME - ACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period
- M = ((ACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

15.4.6 GPMC Use Cases And Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

Table 15-261 lists some of the I/Os of the GPMC module.

Table 15-261. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

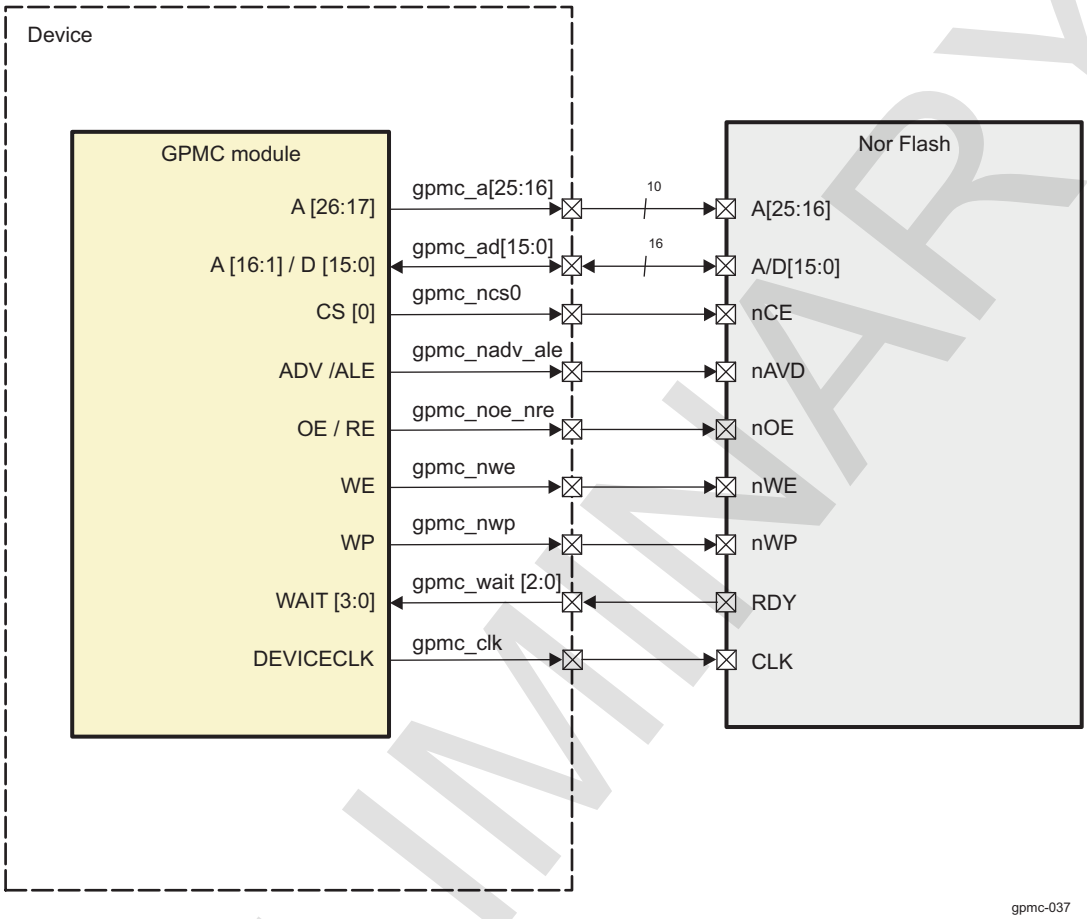
Figure 15-96 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-96. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-262 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-263 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-97 shows the synchronous burst read access.

Table 15-262. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Table 15-262. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-263. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max (tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) OeOnTime (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

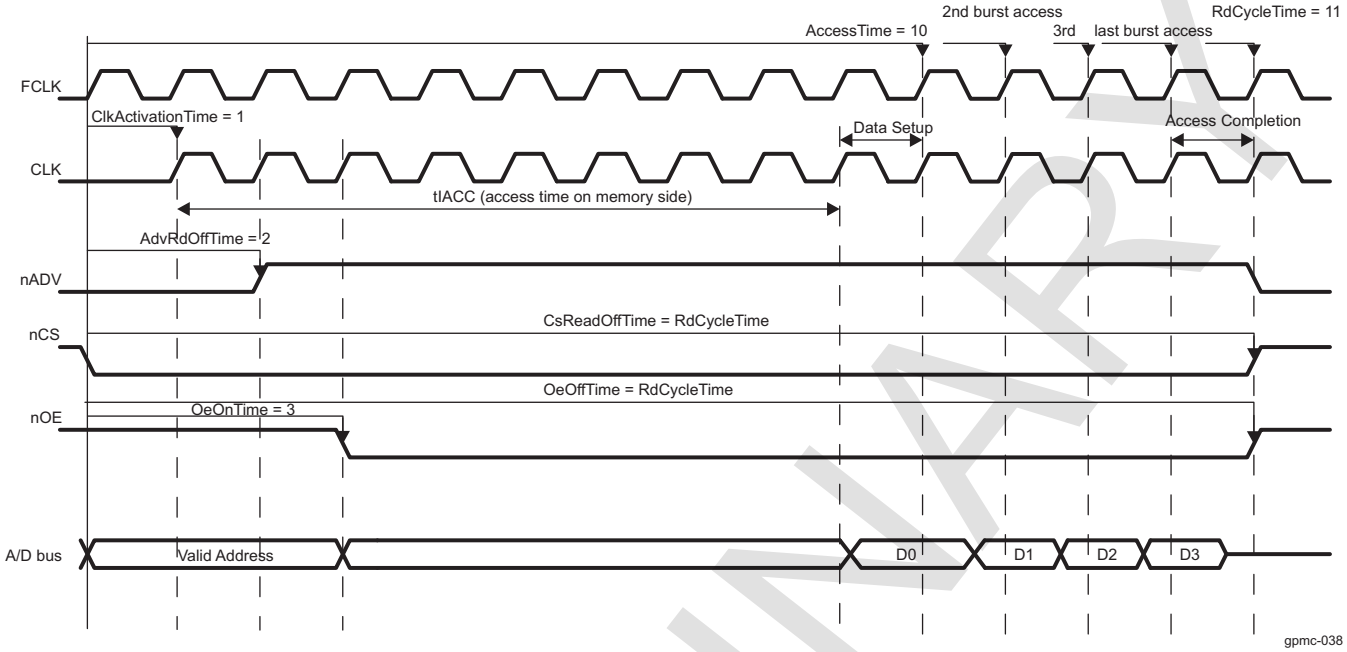
Figure 15-97. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-264 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-265 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-98 shows the asynchronous read access.

Table 15-264. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-264: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

  The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must be configure to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

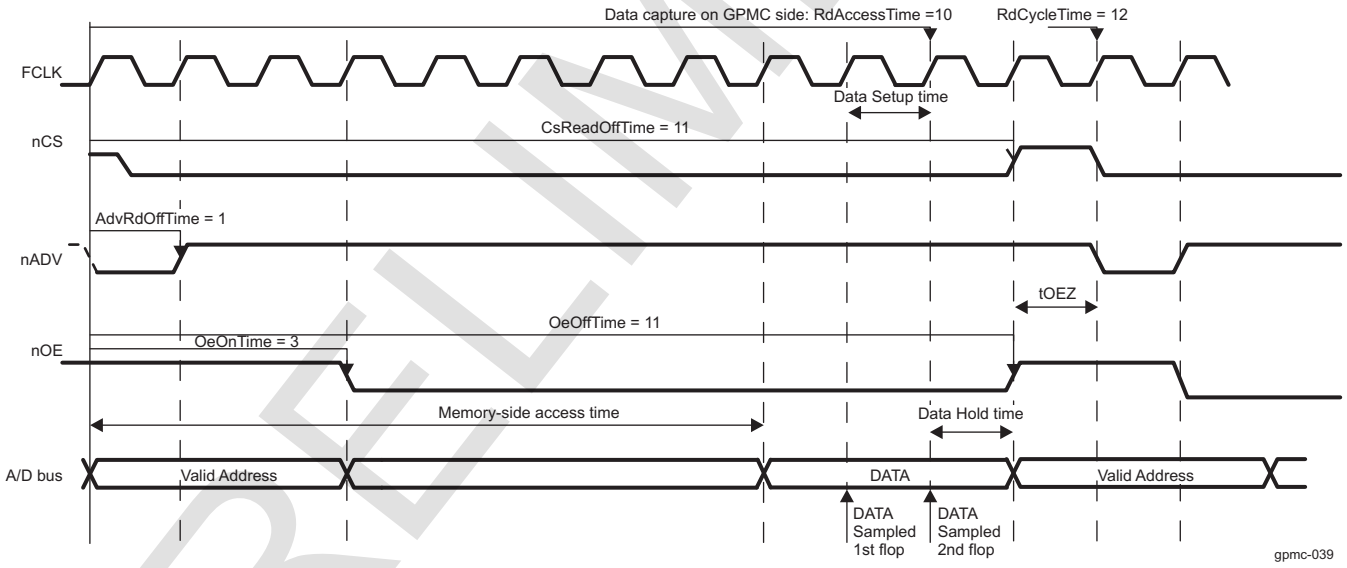
deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 15-265. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	10	ACCESSTIME = 0x0A
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime = AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 15-98. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-267 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-266 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-99 shows the synchronous burst write access.

PRELIMINARY

Table 15-266. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires 1 cycle of data hold time (nCS deassertion).

Table 15-267. GPMC Timing parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

15.4.6.2 How to choose a suitable memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 15-268. Supported memories interfaces

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-269 summarizes the NAND interface signals level applied to external device or memories.

Table 15-269. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H [2]	H [2]	H [2]	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L [3]

(1) RE stands for rising edge, FE stands for falling edge
(2) Can be either nCE high, or WE and nRE high.
(3) nWP should be biased to CMOS high or CMOS low for standby

Copyright © 2011, Texas Instruments Incorporated

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, that is, is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 15-270 summarizes the NOR interface signals level applied to external device or memories.

Table 15-270. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventionnal NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

15.4.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In the whole section i corresponds to the chip-select number, i = 0 to 7.

- GPMC Register Summary: [12]

Table 15-281. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x5000 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					WAIT2EDGEDETECTIONENABLE	WAIT1EDGEDETECTIONENABLE	WAIT0EDGEDETECTIONENABLE	RESERVED						TERMINALCOUNTEVENTENABLE	FIFOEVENTENABLE

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10	WAIT2EDGEDETECTION ENABLE	Enables the Wait2 Edge Detection interrupt 0x0: Wait2EdgeDetection interrupt is masked 0x1: Wait2EdgeDetection event generates an interrupt if occurs	RW	0
9	WAIT1EDGEDETECTION ENABLE	Enables the Wait1 Edge Detection interrupt 0x0: Wait1EdgeDetection interrupt is masked 0x1: Wait1EdgeDetection event generates an interrupt if occurs	RW	0x0
8	WAIT0EDGEDETECTION ENABLE	Enables the Wait0 Edge Detection interrupt 0x0: Wait0EdgeDetection interrupt is masked 0x1: Wait0EdgeDetection event generates an interrupt if occurs	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTEVENT ENABLE	Enables TerminalCountEvent interrupt issuing in prefetch or write-posting mode 0x0: TerminalCountEvent interrupt is masked 0x1: TerminalCountEvent interrupt is not masked	RW	0x0
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt 0x0: FIFOEvent interrupt is masked 0x1: FIFOEvent interrupt is not masked	RW	0x0

15.5 Error Location Module

15.5.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-100 shows the integration of the ELM subsystem in the device.

Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
ELM	ELM_RST	L4_PER_RST	PRCM	Power domain hardware reset For information about PRCM reset sources and distribution, see Section 3.5.4, *Reset Domains* inChapter 3, *Power, Reset, and Clock Management*.

Table 15-347. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A9	BCH error-location module interrupt For information about Cortex-A9 interrupt control, see Section 17.3.2, *Interrupt Requests to Cortex-A9 MPU INTC*.
		D_IRQ_26	DSP	BCH error-location module interrupt For information about DSP interrupt control, see , *Interrupts Requests*.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

Table 15-348 describes the power-management features available to the ELM module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see the Section 3.6.8, *CD_L4_PER Clock Domain* in Chapter 3, *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6 *Clock Management* in Chapter 3, *Power, Reset, and Clock Management*

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Table 15-348. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see Chapter 3, *Power, Reset, and Clock Management*.

15.5.3.3 ELM Interrupt Requests

Table 15-349 lists the event flags, and their masks, that can cause module interrupts.

Table 15-349. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

PRELIMINARY

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 15-350. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

PRELIMINARY

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 15-352 and Table 15-353 describe the processing completion for continuous and page modes, respectively.

Table 15-352. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 15-353. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		

PRELIMINARY

	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-354. Use Case: Continuous Mode

Table 15-354. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-355 are given in decimal format.

Table 15-355. 16-bit NAND Sector Buffer Address Map

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF

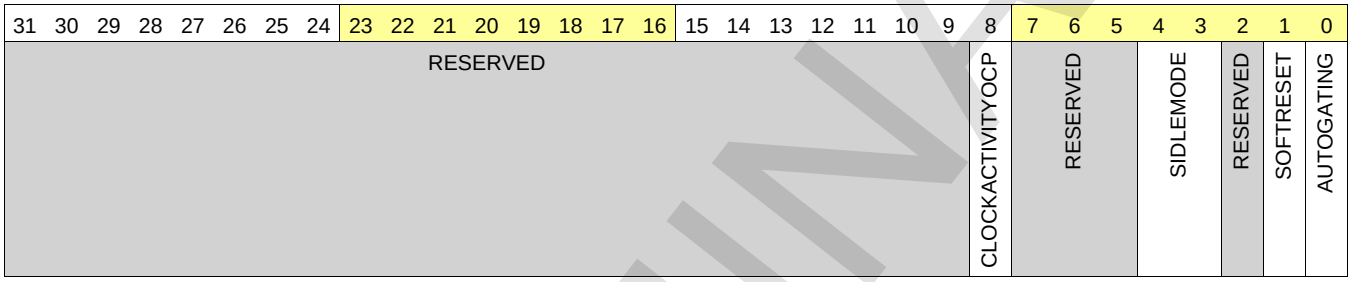
Table 15-361. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP Clock activity when module is in IDLE mode (during wake up mode period) 0x0: OCP Clock can be switch-off 0x1: OCP Clock is maintained during wake up period	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: FORCE Idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: NO idle. IDLE request is never acknowledged. 0x2: SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (During reads, it always returns 0.) It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible impact other than saving power) 0x0: OCP clock is free-running 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are three on-chip memories in the device.

- A 4K-byte SAR read-only memory (ROM)
- A 8K-byte SAR random-access memory (RAM)
- A 56K-byte L3 static random-access memory (L3 OCM_RAM)

There are other on-chip memories located inside other subsystems (Cortex-A9 MPU, DSP IVA-HD, ABE, Cortex-M3 MPU) that are not described in the following sections. Refer to each subsystem chapter for more details.

15.6.2 OCM Subsystem Integration

Figure 15-101 shows the integration of the OCM subsystem to the device.

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR ROM

This on-chip ROM contains 4K bytes of memory and a linked list of descriptors used by the system DMA (sDMA) during the restore context operation (when device transitions from OFF to ON modes).

The device-embedded SAR ROM has the following characteristics:

- 4K-bytes ROM
- 32-bit access per cycle
- Support for single and burst access transactions

  The memory space of the embedded ROM starts at 0x4A05 E000 and ends at 0x4A05 FFFF (8K bytes are reserved, but only 4K bytes are used).

15.6.3.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into OFF mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by the software, so that the sDMA restores its saved content when the device transitions from OFF to ON mode. Locations not used by the sDMA can be used as a scratch-pad memory by the software. It is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
  - Operates at full L4-PER interconnect clock frequency
  - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4KB): Starts at 0x4A32 6000 and ends at 0x4A32 6FFF

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- SAR space 2 (1KB): Starts at 0x4A32 7000 and ends at 0x4A32 73FF
- SAR space 3 (2KB): Starts at 0x4A32 8000 and ends at 0x4A32 87FF
- SAR space 4 (1KB): Starts at 0x4A32 9000 and ends at 0x4A32 93FF

15.6.3.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56K bytes of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
  - Operates at full L3 interconnect clock frequency
  - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
  - A region-based partitioning (refer to L3 firewall description)
  - The module owner of the access, with respect to its read and write permissions to that region
  - The transaction attributes of the access, with respect to the region permission properties. See Section 13.2, *L3 Interconnect* for details.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4030 DFFF.

16.1 sDMA Module Overview

The system direct memory access (sDMA) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see Section 3.1.2.3, *Dynamic Power Switching*, in Chapter 3, *Power, Reset and Clock Management*.

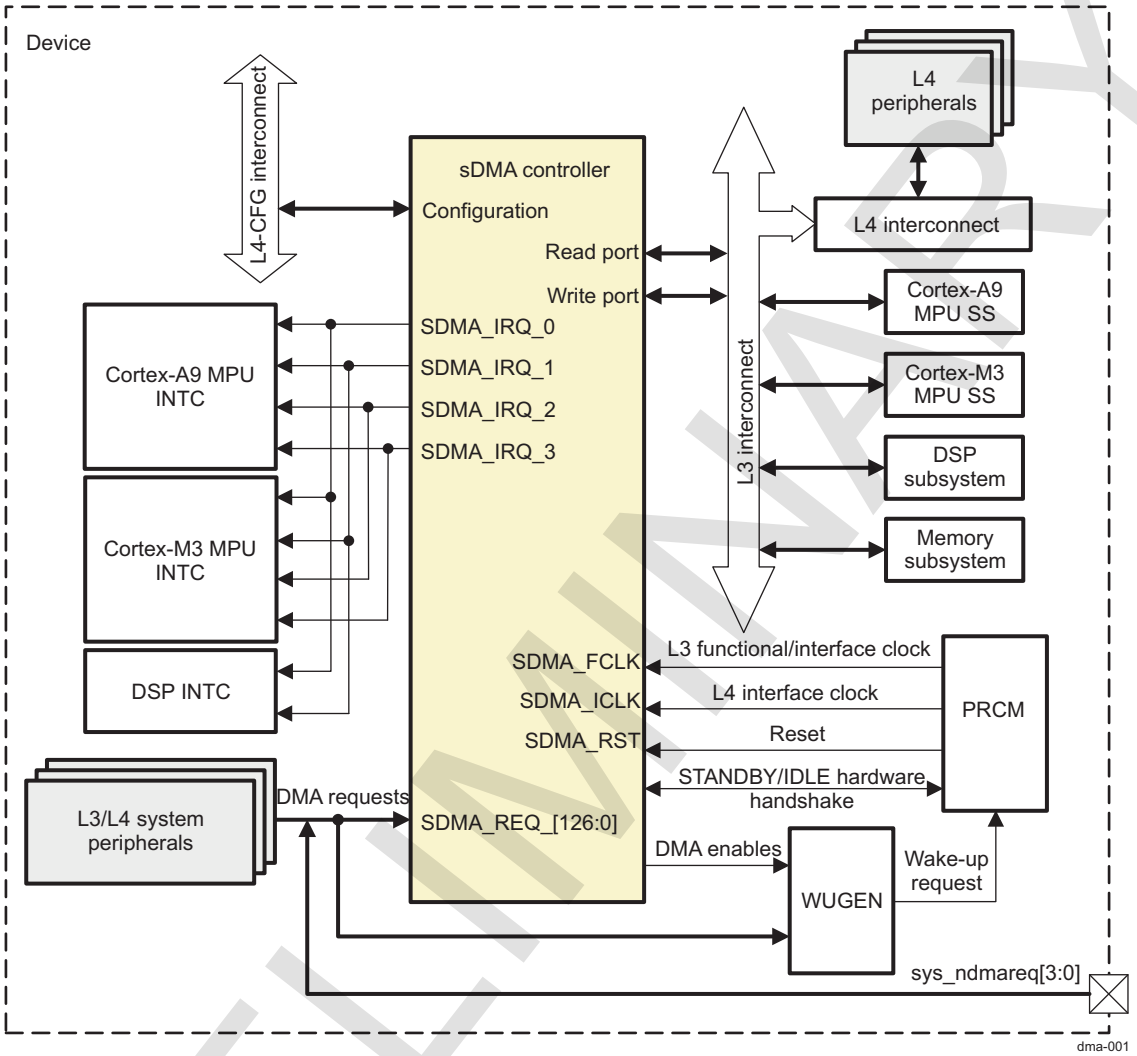
Figure 16-1 shows an overview of the sDMA module.

Figure 16-1. sDMA Overview



The sDMA module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the sDMA through the L4-CFG interconnect.

16.2 sDMA Controller Environment

The sDMA controller supports external DMA requests through the sys_ndmareq[3:0] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

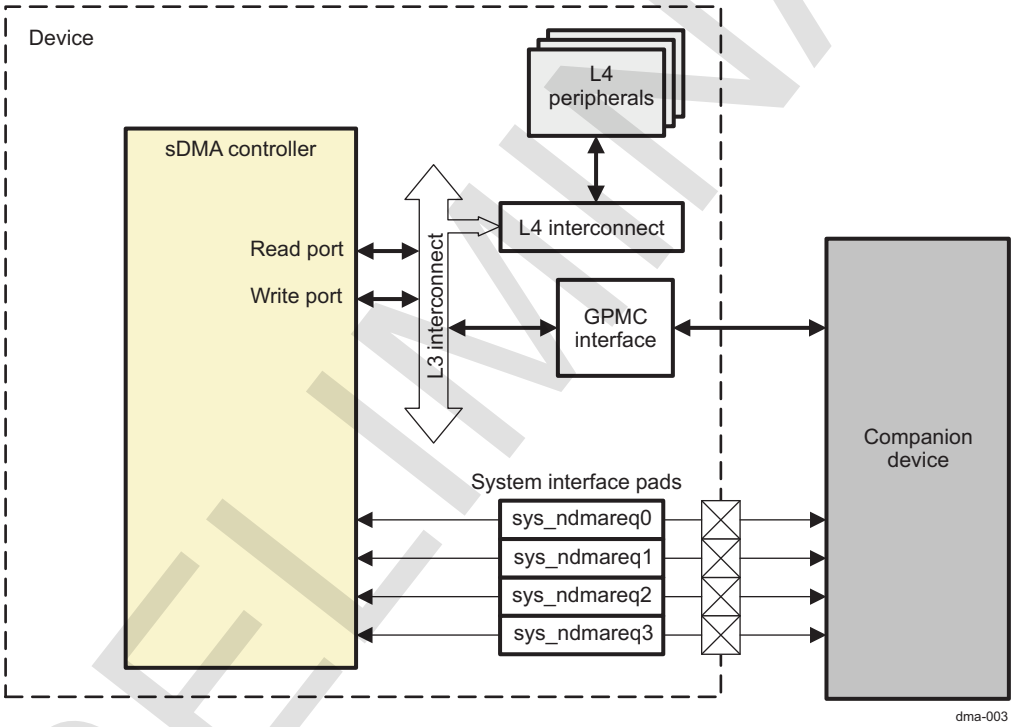
Table 16-1. External sDMA Request Signals

Signal Name	I/O [1]	Description
sys_ndmareq0	I	External DMA request 0 (system expansion)
sys_ndmareq1	I	External DMA request 1 (system expansion)
sys_ndmareq2	I	External DMA request 2 (system expansion)
sys_ndmareq3	I	External DMA request 3 (system expansion)

(1) I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the sDMA environment.

Figure 16-2. Example of External DMA Requests Use



An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the four signal lines to pins, see Chapter 18, *Control Module*.

All 127 DMA request lines are transition-sensitive.

For a transition-sensitive DMA request (see Figure 16-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_ICLK):

- When the deassertion time is less than one clock cycle, the sDMA may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not

Copyright © 2011, Texas Instruments Incorporated

detect the DMA request.

Table 16-3. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
sDMA	SDMA_FCLK	DMA_L3_ICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
	SDMA_ICLK	DMA_L4_ICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
sDMA	SDMA_RST	SDMA_RET_RST	PRCM	Hardware reset. It initializes all internal logic of the sDMA module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, *Power, Reset, and Clock Management*.

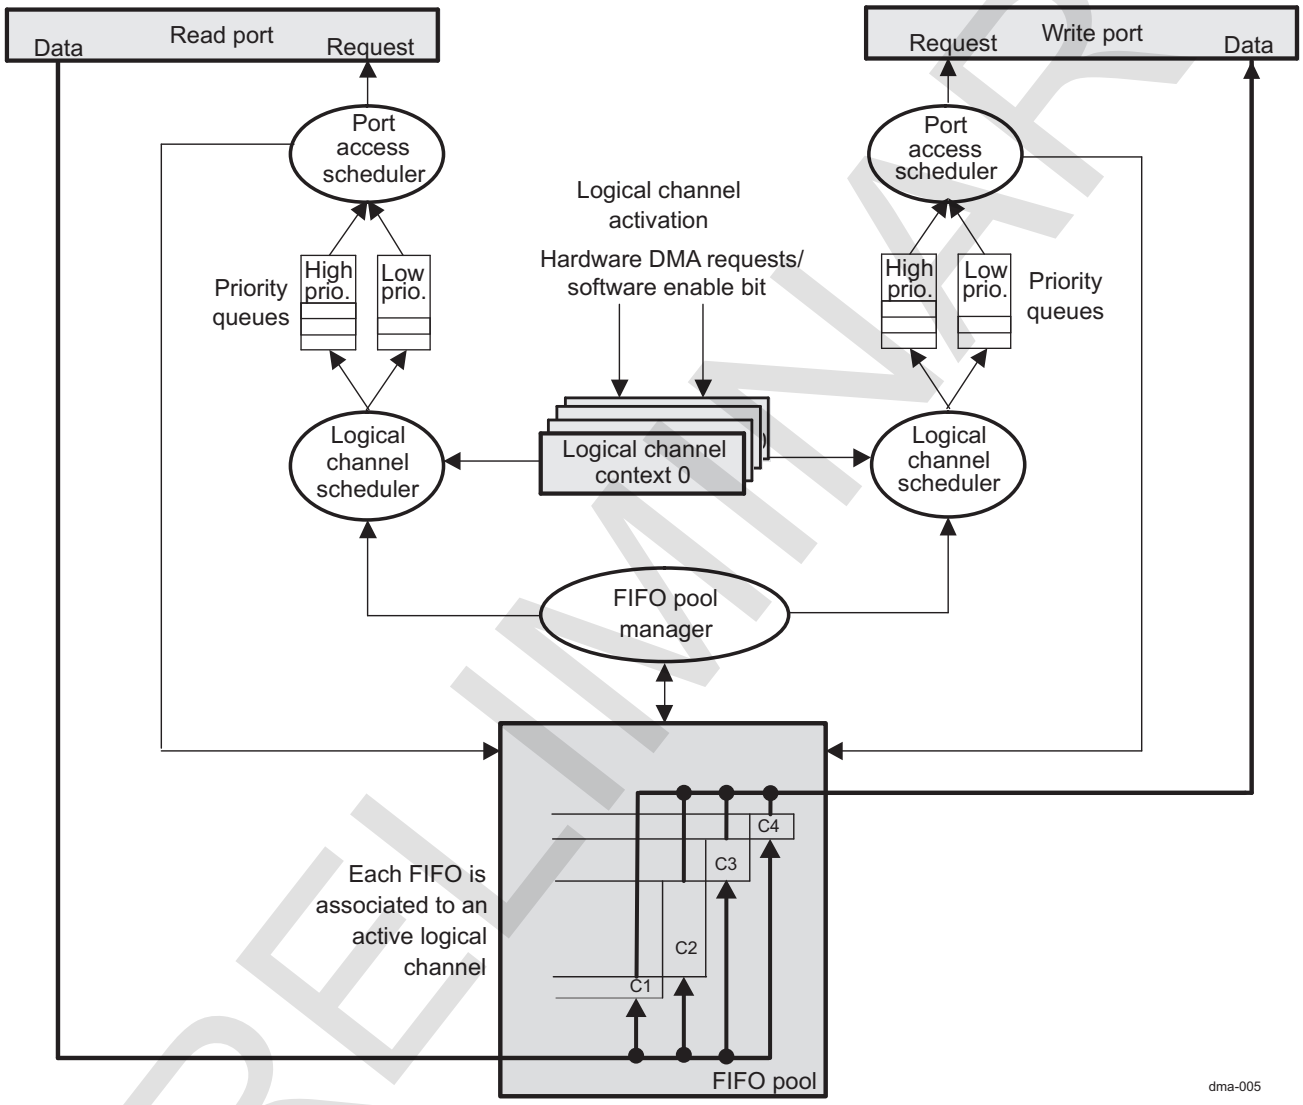
16.4 sDMA Functional Description

The sDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the sDMA controller top-level block diagram.

Figure 16-5. sDMA Controller Top-Level Block Diagram



16.4.1 sDMA Controller Power Management

Table 16-6 describes power-management features available for the sDMA controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 16-6. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG[0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG[9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-7.
Master standby modes	DMA4_OCP_SYSCONFIG[13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-7. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and sDMA clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

16.4.2 sDMA Controller Interrupt Requests

DMA4 has four interrupt lines (Lj, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the DMA4_IRQENABLE_Lj bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the DMA4_CSRi registers, the DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the DMA4_IRQENABLE_Lj registers.
- The DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the DMA4_IRQENABLE_Lj bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the DMA4_CICRi register. Each status bit is updated in the DMA4_CSRi register only when the corresponding enable bit is enabled in the DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*:

- Identify the channel (LCH*i*) generating the interrupt.

  Read DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* DMA4_CSRi. For example, if the drop event (the DMA4_CSRi[1] DROP bit) is 1, a

Copyright © 2011, Texas Instruments Incorporated

request collision will occur.

The interrupt event status bit in the DMA4_CSRi register is immediately reset after it is written to 1.

The interrupt status bit in the DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The sDMA module has four interrupt request output lines, SDMA_IRQ_0 to SDMA_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 16-8 occurs.

Table 16-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel DMA4_CSRi register.

16.4.3 Logical Channel Transfer Overview

As Figure 16-5 shows, the sDMA module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation

  A logical channel becomes active as follows:
  - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, start address alignment, addressing mode, and

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

configured maximum burst size, each transaction can be a single access or a burst of accesses.

- Logical channel scheduling

  When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

  In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_ PRIORITY) in the logical channel DMA4_CCRi register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

  NOTE: The DMA4_GCR[23:16] ARBITRATION_RATE bit field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field. The ARBITRATION_ RATE bit field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The sDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 16.4.2.1, *Interrupt Generation*).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

transfer block size = FN × EN × ES

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see Section 16.4.2.1, *Interrupt Generation*).

The DMA4_CFNi register configures the FN in a block.

The DMA4_CENi register configures the EN.

The DMA4_CSDPi register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

Note: Constant addressing mode with DMA4 to/from DDR memory is not supported on the OMAP4460 device.
To fill DDR memory with a single value, the constant fill feature of DMA4 must be used instead of a constant addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n + 1) = A(n) + ES + (FI\ 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI\ 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI\ 1) * ES] + 1$$

where:

A(n): Byte address of the element *n* within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element *n* to the start of next element, *n+1*.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNi.

Figure 16-6 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in Figure 16-10.) The double-index addressing example shown in Figure 16-6 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 16-6 through Figure 16-9 show examples of addressing mode configurations. Table 16-9 lists parameter values for the examples.

Figure 16-9. Addressing Mode Example (c)

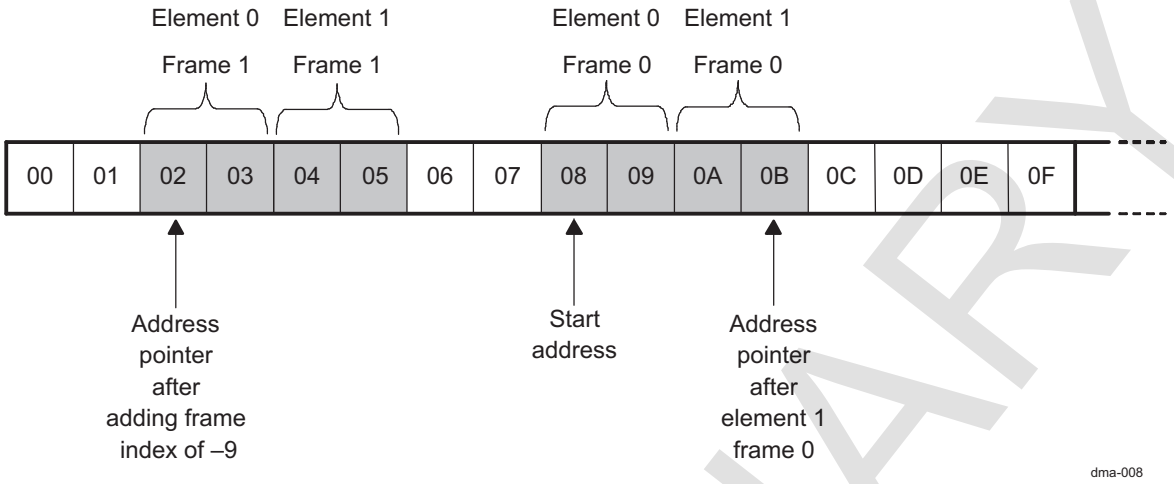

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360 – xx) degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y–1)	ES*(x*y–1)	ES*y*(x–1)
	EI	ES*(y–1) + 1	1–2*ES	1–ES*(y + 1)
	FI	1 ES*[(x–1)*y + 2]	1–2*ES	1+ES*(x–1)*y
Double indexing on source (read)	Base address	ES*x*(y–1)	ES*(x*y–1)	ES*(x–1)
	EI	1–ES*(x + 1)	1–2*ES	ES*(x–1) + 1
	FI	1+ES*(y–1)*x	1–2*ES	1 ES*[(y–1)*x + 2]

Table 16-11 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 × 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

PRELIMINARY

Rotations:

Section 16.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

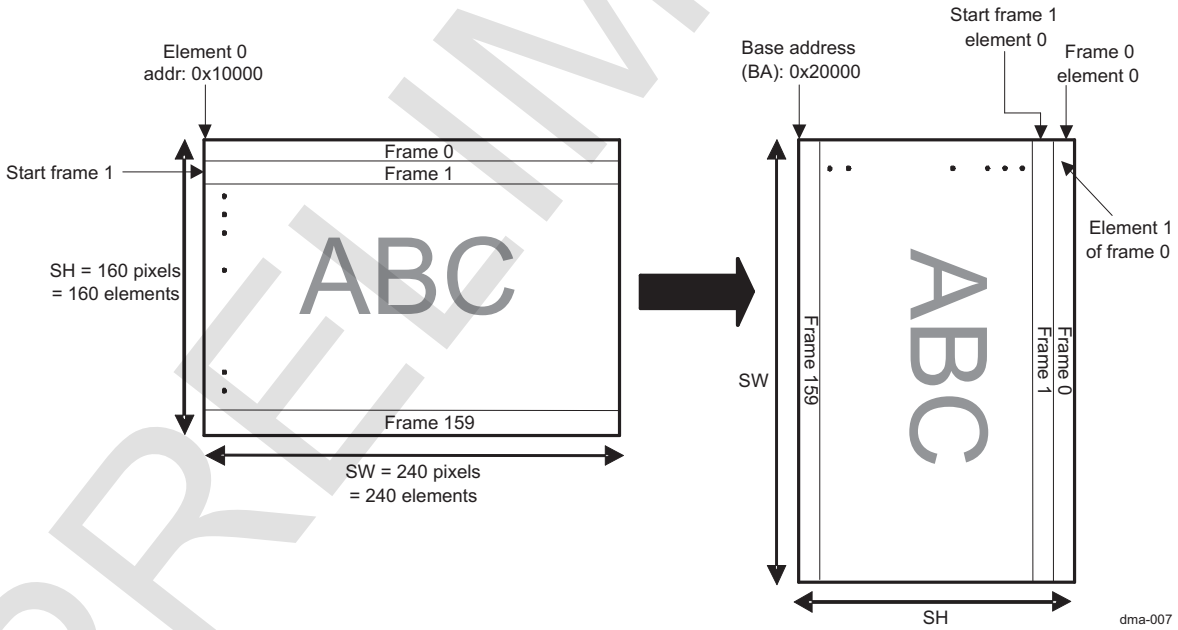
Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	–[(SW-1)*SH + 1] = 38,241 elements
Start address	0x100000	0x200000 + (SH 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI 1) * ES] + 1 = 1	[(Stride EI 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI 1) * ES] + 1= 1	[(Stride FI 1) * ES] + 1 = 152,967

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation



16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the DMA4_CSDPi register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the sDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel DMA4_CSDPi register.

NOTE: Because the device is little-endian by construction, the sDMA endianism registers must never be set to big-endian.

If sDMA is used to execute endian conversion by the setting source and destination to different endianism values, it is important to consider that the L3 interconnect also executes endian conversion if the sDMA and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA DMA4_CCRi[4:0] and DMA4_CCRi[20:19] bit fields to 0. The transfer starts as soon as the DMA DMA4_CCRi[7] bit is set (when it enters the scheduling process).

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 16-8).

Specify the DMA request number in the DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the DMA4_CCRi[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the DMA4_CCRi[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4_CCRi register and the DMA4_CCRi[5] FS and DMA4_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit through either the channel DMA4_CDFIi register (source synchronized) or the DMA4_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

  The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 16.4.13, *Reprogramming an Active Channel*).

Copyright © 2011, Texas Instruments Incorporated

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

  The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA4_CCRi[23] PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 16.4.4, *FIFO Queue Memory Pool*).

  Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the DMA4_CSDPi[17:16] WRITE_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The DMA4_CCRi[25] BUFFERING_DISABLE bit must be filled with an allowed value, as specified in Table 16-12.

Table 16-12. Buffering Disable

	BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC (DMA4_CDACi):

  Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

  The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see Section 16.5.4, *Synchronized Transfer Monitoring Using CDAC*).

Copyright © 2011, Texas Instruments Incorporated

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 16.5.5, *Concurrent Software and Hardware Synchronization*):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register DMA4_GCR[13:12] .

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 = No ThreadID is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x1 = Read ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 = Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 = Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 = No ThreadID is reserved for high-priority channels
- DMA4_GCR[13:12] = 0x1 = Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 = Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 = Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (DMA4_CCRi[26]) is added for write priority, and the previous priority bit becomes read priority bit (DMA4_CCRi[6]).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel = High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel = Low Budget FIFO

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see Section 16.5, *sDMA Basic Programming Model*.

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the DMA4_CCRi[7] ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the DMA4_CCRi register (DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

Copyright © 2011, Texas Instruments Incorporated

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the DMA4_CSFIi and DMA4_CDFIi configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4_CSFIi[15:0] bit field is used to specify the packet data size in the DMA4_CSFIi register. The user must set the DMA.SDMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4_CDFIi[15:0], is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4_CDFIi register, the user must set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0.

  NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

  The packet synchronization mode is active when DMA4_CCRi[5] FS = DMA4_CCRi[18] BS = 1. Then:

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0, the DMA4_CDFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CDFIi[31:16] bit field is unused for the packet size.

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 1, the DMA4_CSFIi[15:0] bit field gives the number of element in the packet and the DMA4_CSFIi[31:16] bit field is unused for the packet size.

  NOTE: The maximum transfer size, regardless of the packet size, is always:

  Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size.

  If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.4.15 Graphics Acceleration Support

The sDMA supports two graphic acceleration features: transparent copy and constant fill.

Copyright © 2011, Texas Instruments Incorporated

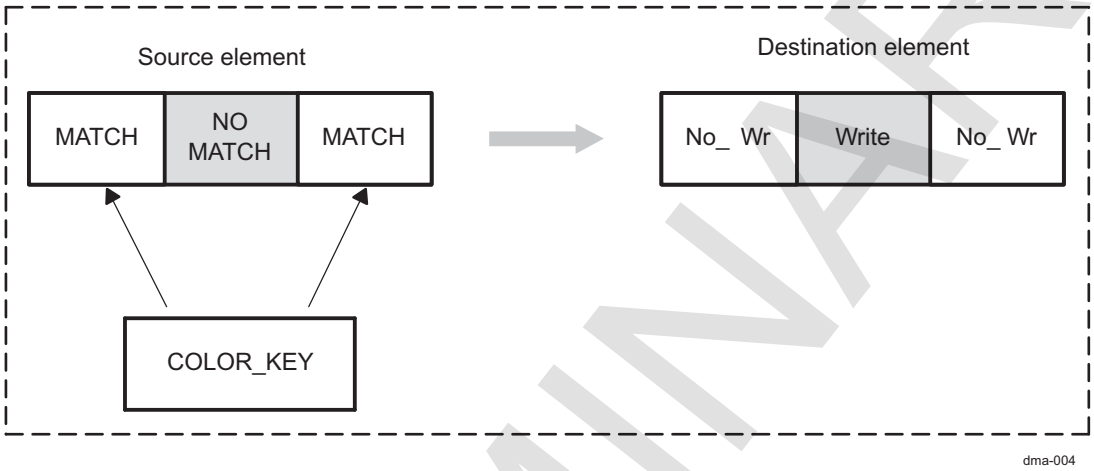
PRELIMINARY

Only one of these features can be enabled at a time through the DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4_COLORi register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

Figure 16-11. 2-D Graphic Transparent Color Block Diagram



The constant fill feature provides the ability to specify a particular color through the DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the DMA4_CCRi[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its DMA4_CSDPi[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled (DMA4_CCRi[25] BUFFERING_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see Section 16.4.19, *FIFO Draining Mechanism*.

Copyright © 2011, Texas Instruments Incorporated

16.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no longer active on the write port) and if the DMA4_CICRi[12] DRAIN_END_IE is set to 1, the DMA4_CSRi[12] DRAIN_END status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and DMA4_CCRi[25] BUFFERING_DISABLE = 0 and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 Linked List

16.4.20.1 Overview

The sDMA supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

Copyright © 2011, Texas Instruments Incorporated

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (DMA4_CNDPi) and a channel-descriptor parameter register (DMA4_CDPi) . The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- DMA4_CICRi (interrupt event mask)
- CFN (frame number)
- Bit fields:
  - P: Corresponds to the PAUSE_LINK_LIST bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the PAUSE_LINK_LIST bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the DMA4_CICRi register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where DMA4_CICRi is fully specified.
  - Nxt_Dv, Nxt_Sv: Mapped in the DMA4_CDPi register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
  - Next_Descriptor_Type: Specifies the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the DMA4_CDPi register

16.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified; for example, bursting and packing (included in the DMA4_CSDPi register)
- Attach a new DMA request to the same channel or change the priority or access privilege (included in the DMA4_CCRi register)
- Enable solid or transparent color fill (included in the DMA4_CCRi and DMA4_COLORi registers)
- Enable a channel link (included in the DMA4_CLNK_CTRLi register)

16.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-14 shows a type 2 descriptor with source and destination address updates. Table 16-15 shows a type 2 descriptor with one source or destination address update.

16.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). Table 16-16 shows a type 3 descriptor with source and destination address updates. Table 16-17 shows a type 3 descriptor with one source or address destination update.

16.4.20.4 Linked-List Control and Monitoring

16.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPi[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- DMA4_CDPi[9:8] TRANSFER_MODE = 00: The current channel is using normal mode.
- DMA4_CDPi[9:8] TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4_CDPi[9:8] TRANSFER_MODE = 0).

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the DMA4_CCRi[7] ENABLE bit to 1). The DMA4_CDPi[10] FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the DMA4_CCENi (remaining elements) and DMA4_CCFNi (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, DMA4_CCDNi (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the DMA4_CCDNi register to 0 during the initial configuration. When the DMA4_CCDNi register is updated, the DMA4_CCFNi and the DMA4_CCENi registers are updated. The user must also initialize the DMA4_CCFNi and DMA4_CCENi registers to 0xFFFF and to 0xFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The DMA4_CICRi register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the DMA4_CICRi and DMA4_CSRi registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full DMA4_CICRi update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the DMA4_CDPi[7] PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel DMA4_CDPi[7] PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the DMA4_CDPi[7] PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

  A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.

  – The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
  – The linked list can be resumed by resetting the DMA4_CDPi[7] PAUSE_LINK_LIST bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

  A channel is a drain candidate if it is a hardware-source-synchronized transfer with DMA4_CCRi[25]

Copyright © 2011, Texas Instruments Incorporated

BUFFERING_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).

- Drain trigger:

  A drain candidate channel is drained if it is disabled (DMA4_CCRi[7] ENABLE = 0) or if it receives a transaction error on the read port.

- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

  A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with DMA4_CCRi[25] BUFFERING_DISABLE = 1.

- Abort trigger:

  A channel is an abort candidate if it is disabled (DMA4_CCRi[7] ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.

- Abort behavior with a type 1, 2, or 3 descriptor:

  If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

  In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the DMA4_CSRi[6] SYNC, DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the DMA4_CSRi[6] SYNC bit becomes active (DMA4_CSRi[6] SYNC = 1) when the first data load transaction is scheduled and remains active until the last data load transaction in the block (not super block) is descheduled (DMA4_CSRi[6] SYNC = 0). The SYNC bit is not active during the descriptor load phase.
- The DMA4_CCRi[9] RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  - When (during the descriptor load phase) the last descriptor write request is descheduled
  - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The DMA4_CCRi[10] WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCRi[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.4.20.4.8 Linked-List Channel Linking

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]- CHx[DES1] - . - CHx[DESN]-CHx[DataN + 1]

CHz: CHz[Data1]- CHz[DES1] - . - CHz[DESM]-CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]- CHx[DES1] - . - CHx[DESN]-CHx[DataN+1] - CHz: CHz[Data1]- CHz[DES1] - . - CHz[DESM]-CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]- CHx[DES1] -.- CHx[DESp]-CHx[Data(p + 1)] - CHz[Data1]- CHz[DES1] - .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

16.4.21 Auto-Restore Feature

The auto-restore feature is introduced mainly to accelerate the restore process, which otherwise is complex and time and resource consuming. In many system applications, it is required that the modem wake up and use only a few modules to wake up, without the intervention of the main MPU (Cortex-A9 MPU). The MPU still may be in off mode; however, some modules may need to come out of off mode. The sDMA can be used to restore the register contents of these modules. The auto-restore feature consists in saving the register data into a memory (SAR RAM in the WKUP domain) that remains powered even during off mode, and then in automatically retrieving data when returning from off mode.

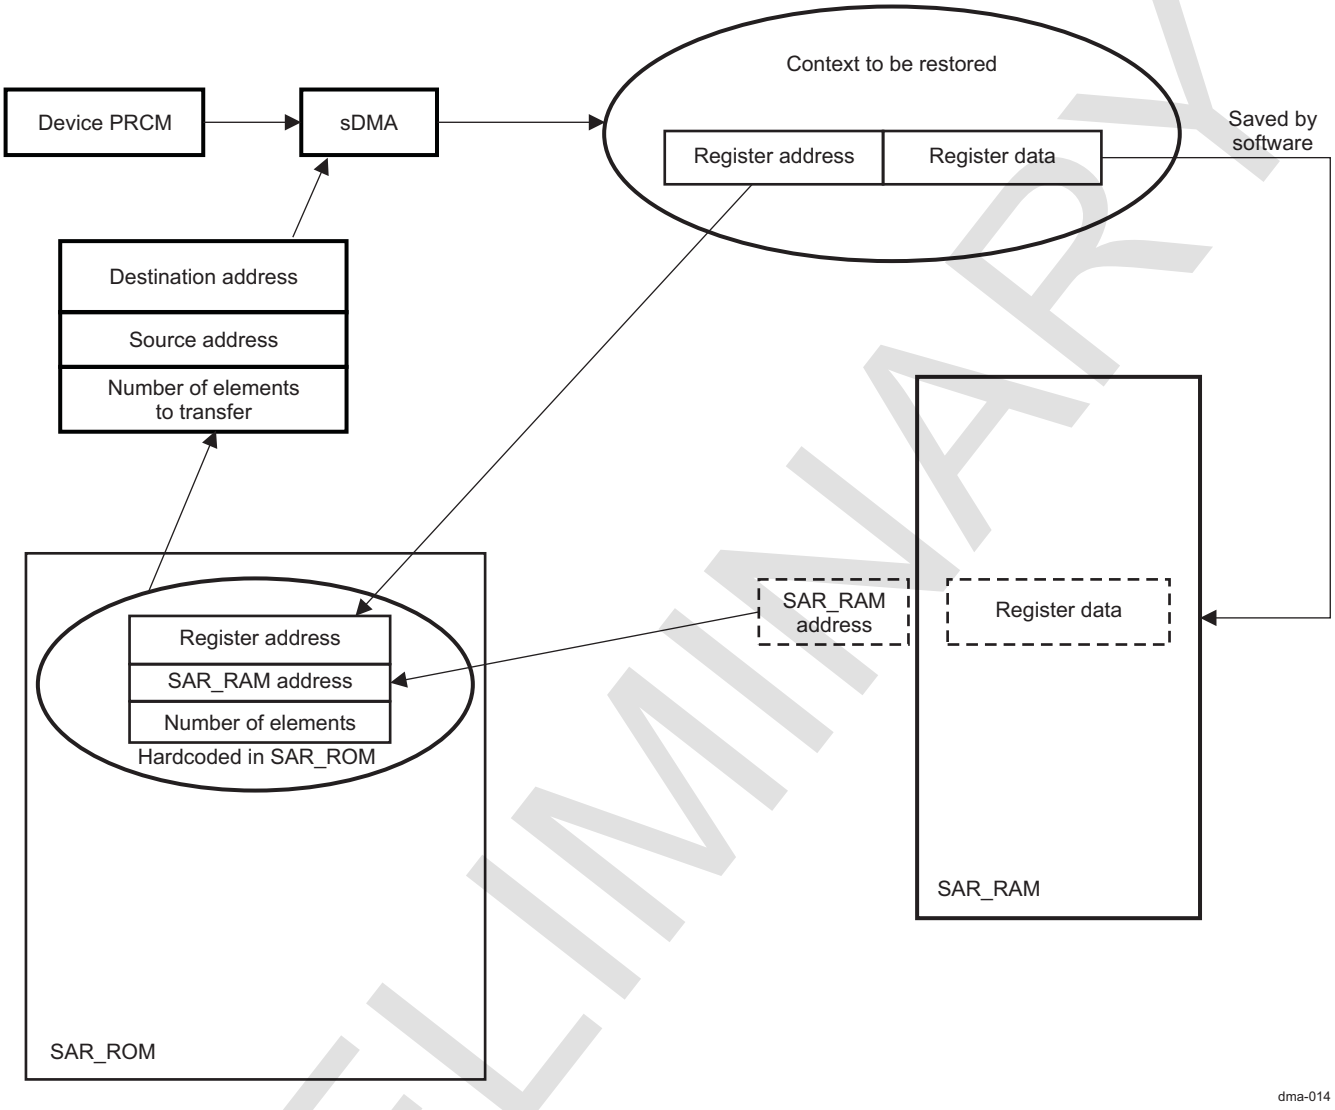
The restore feature is enabled by default and cannot be disabled.

Figure 16-12 is an overview of the save-and-restore mechanism using SAR RAM and SAR ROM.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 16-12. Overview of Save-and-Restore Mechanism Using SAR RAM and SAR ROM



16.4.21.1 Save Process

The save process is done entirely by software; the sDMA module normally is not involved. Software must save the data to be restored in a dedicated location in SAR RAM. To reduce the save sequence execution time, the sDMA can be used with linked-list descriptors. These save descriptors are symmetrical with regards to descriptors in the SAR ROM.

The register content to be saved can be the register value before going into off mode or a value that is required on wake up. This means that the restored register value can differ from the last value of the register before going into off mode.

The following registers are affected:

- CM1 and CM2 configuration

  Bits 0 of the CM_SHADOW_FREQ_CONFIG1 register and the CM_SHADOW_FREQ_CONFIG2 register are self-clearing and must be set at restore time. Thus, these data must always be overwritten in the SAR RAM.
- Because USBHOSTHS and USBTLL restore requires a particular sequencing, software must overwrite data read from the following registers implied in phase2a and phase 2b:
  - CM_L3INIT_HSUSBHOST_CLKCTRL_RESTORE

Copyright © 2011, Texas Instruments Incorporated

– CM_L3INIT_HSUSBTLL_CLKCTRL_RESTORE
– CM_SDMA_STATICDEP_RESTORE

The USBHOSTHS and USBTLL modules must be put in a particular mode when saving (and restoring) their context. In the case of context saving, software must:

- Configure the L3INIT clock domain to SW_WKUP to ensure module transitions
- Disable both modules
- Assert the SAR_MODE pins
- Enable back both modules. Optional clocks must be kept gated
- Save both modules context
- Disable both modules
- Deassert SAR_MODE pins
- At this point, software may enable back both modules and get the L3INIT clock domain out from SW_WKUP state.

16.4.21.2 Restore Process

As explained earlier, every time modem wakes up, the MPU must not necessarily wake up. This needs an automated way of restore. For example, when mobile is in roaming, and not in active use, it needs to change base stations. For this task, the MPU need not wake up, only a few peripherals/subsystems need to be in ON mode. Before executing any task, we need to restore their register contents.

16.4.21.2.1 PRCM and sDMA interaction During Restore Phase

Restore is performed during three phases. At the end of each phase, the sDMA stops and waits for the PRCM to perform the next phase transfer. For more information, see Section 3.9.3.2, *Device Off Mode Wake-Up Sequences*, in Chapter 3, *Power, Reset, and Clock Management*.

16.4.21.2.2 sDMA Descriptors Description

The restore phase is done automatically by the sDMA. The sDMA gets the register address (destination address), number of elements to transfer, and the address of the data to transfer (Source address) from SAR ROM. As mentioned previously, the register data is stored in the SAR RAM.

The SAR ROM contains two types of descriptors the DMA-4 should use:

- Type-1 descriptors:

  Type-1 descriptors (48 bytes) are used at the beginning of each phase. In addition to the source and destination address and number of elements, these descriptors contain the required data that initializes the sDMA. Table 16-13 shows the Type-1 descriptor structure.
- Type-3 descriptors with source and destination address update:

  Type-3 descriptors (16 bytes) are used for subsequent sDMA transfers and mainly contain the source and destination address and number of elements. Table 16-16 shows the Type-3 descriptor structure.

  Figure 16-13 is an example of SAR ROM code (Type-3 descriptor).

Figure 16-13. Type-3 SAR ROM Code Example

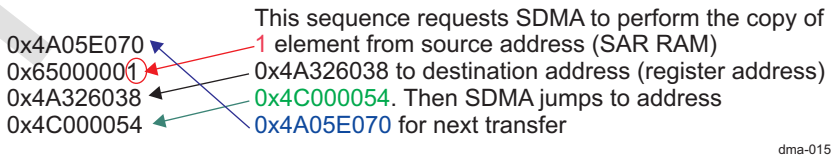


Figure 16-14 is an example of last DMA transfer (Type-3 descriptor). To indicate to the DMA that this is the last transfer, the next descriptor address must be set to 0xFFFFFFFC, as shown in the figure.

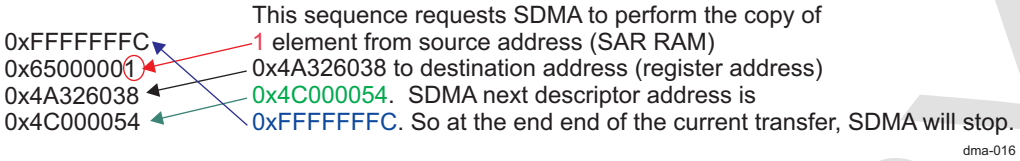
PRELIMINARY

Figure 16-14. Type-3 SAR ROM Last Transfer Example



16.4.21.3 SAR RAM

The SAR RAM contains the data that needs to be maintained during off mode. The SAR RAM is split into three banks (see Table 16-18).

Table 16-18. SAR RAM Allocation

Access Mode	Bank	Address Range
Public	1 (SAR_RAM_1)	0x4A32_6000–0x4A32_6FFF (4KB)
Public, for I/O pad	2 (SAR_RAM_2)	0x4A32_7000–0x4A32_73FF (1KB)
Public	3 (SAR_RAM_3)	0x4A32_8000–0x4A32_87FF (2KB)

16.4.21.4 SAR ROM

The SAR ROM contains the list of registers that need to be saved before off mode and then restored after off mode, and where the register data is stored in SAR RAM. The SAR ROM start address is 0x4A05_E000.

When exiting off mode, PRCM automatically redirects the sDMA to address:

- 0x4A05_E000 for phase 1 (in SAR ROM)
- 0x4A05_E030 for phase 2a (in SAR ROM)
- 0x4A05_E060 for phase 2b (in SAR ROM)

The SAR ROM is built so that sDMA performs all the transfers for each phase. At the end of each phase, the sDMA stops. The PRCM module then requests to perform the next phase transfer, depending on the wake-up source.

Remarks:

- Phase 1 is always to happen; the restore mechanism is enabled by default and cannot be disabled.
- Phase 2 (2a and 2b) is to happen depending on the wake-up source from off mode. Phase 2 is not performed if C2C is the wake-up source, but it is performed for all other wake-up sources. Therefore, it is mandatory to fill the SAR RAM locations used for USB restore correctly, even if USB is not used, because the restore sequence will happen.
- The USB host restore is to be performed before the USB TLL restore.

NOTE: Some consecutive address registers cannot be saved/restored with burst. This is the case for:

- CLK1_DSS_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK1_DSS_BW_REGULATOR.L3_BW_R_WATERMARK registers
- CLK2_XXX_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK2_XXX_BW_REGULATOR.L3_BW_R_WATERMARK registers, where XXX = ISS, IVAHD, and SGX.

To avoid the failure of an sDMA transfer, the transfer of the previous registers is performed using a single sDMA transfer.

16.4.21.5 SAR RAM Memory Allocation Reserved for Save and Restore

The memory size of the SAR RAM reserved for the save-and-restore mechanism is:

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- 57 percent (2344 bytes) reserved for the SAR mechanism from SAR_RAM_1. The whole SAR_RAM_1 size is 4KB.
- 40 percent (408 bytes) reserved for the SAR mechanism from SAR_RAM_2. The whole SAR_RAM_2 size is 1KB.
- 51 percent (1052 bytes) reserved for the SAR mechanism from SAR_RAM_3. The whole SAR_RAM_3 size is 2KB.

The free part of the SAR RAM can be used by the user software to store any data that needs to be in always-on memory.

16.4.21.6 Register Mapping in SAR RAM

Table 16-19 describes the SAR_RAM_1 memory mapping.

Table 16-19. SAR_RAM_1 Memory Mapping

Order	Register Name	Register Start Address	Register End Address	Size	SAR_RAM_1 Address
1	EMIF1.EMIF_LPDDR2_NVM_CONFIG	0x4C00000C		4	0x4A326000
2	EMIF1.EMIF_SDRAM_CONFIG	0x4C000008		4	0x4A326004

16.5 sDMA Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the DMA4_GCR register, and any required interrupts must be enabled through the DMA4_IRQENABLE_Lj registers and the logical channel DMA4_CICRi registers.

Software clears the DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES (8, 16, or 32 bits) in the DMA DMA4_CSDPi[1:0] bit field.
     - Read and write port access types (single/burst), DMA DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14] bit fields
     - Source and destination endianism, DMA DMA4_CSDPi[21] and DMA4_CSDPi[19] bits
     - Write mode (posted or nonposted) and DMA DMA4_CSDPi[17:16] bit field
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA DMA4_CSDPi[6] and DMA4_CSDPi[13] bits
   - DMA4_CENi: EN
   - DMA4_CFNi: FN per transfer block
   - DMA4_CSSAi and DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - DMA4_CCRi:
     - Read and write port addressing modes, DMA DMA4_CCRi[13:12] and DMA4_CCRi[15:14] bit field
     - Priority bit for both read and write ports, DMA DMA4_CCRi[6] and DMA4_CCRi[26] bits
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
   - DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA DMA4_CCRi[7] bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
      *)malloc(sizeof(DMA4_t));
/* Init. parameters
      */
DMA4-DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4-ReadPortAccessType = 0; //
      DMA4_CSDPi[8:7]
DMA4-WritePortAccessType = 0; //
      DMA4_CSDPi[15:14]
DMA4-SourceEndiansim = 0; //
      DMA4_CSDPi[21]
DMA4-DestinationEndianism = 0; //
```

PRELIMINARY

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization DMA4_CCRi[5] FS bit and the block synchronization DMA4_CCRi[18] BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

NOTE: The user must take care when setting the DMA4_CCRi[23] PREFETCH bit it is in conjunction with DMA4_CCRi[24] SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  4. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  5. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  6. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  7. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  8. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  9. Set both FS and BS to 0 in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  10. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  5. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  6. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  7. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  8. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  9. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  10. Set FS to 1 and BS to 0, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  11. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN

PRELIMINARY

bit field.

6. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
7. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
8. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
9. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
10. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
11. Set FS to 0 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
12. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

- To configure an LCh to transfer one packet per DMA request:

1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCRi [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the DMA4_CSFIi register and set the addressing mode of source to constant addressing in DMA4_CCRi[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the DMA4_CDFIi register and set the addressing mode of destination to constant addressing in DMA4_CCRi[15:14] DST_AMODE bit field.
4. Set the number of elements per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
5. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
6. Set the element number in the packet in the DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
7. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
8. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
9. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the DMA4_CCRi[7] ENABLE bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the DMA4_CDACi register.
2. Enable the channel.
3. If a time-out occurs, read DMA4_CDACi register.
4. If DMA4_CDACi != 0 (it is the value configured in DMA4_CDACi):

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

This indicates that the corresponding transfer has started. The user can then rely on DMA4_CCENi and DMA4_CCFNi element and frame counters.

Otherwise, if DMA4_CDACi = 0 (it is the value configured in the DMA4_CDACi):

This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field to 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: set DMA4_CCRi[26] WRITE_PRIORITY = 1.

   Channel 5 is a read high priority channel: set DMA4_CCRi[6] READ_PRIORITY = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in Section 16.5.5, *Concurrent Software and Hardware Synchronization*.
2. For each channel in the chain, configure the DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit field.
   - Include the logical channel to the chain and enable link by setting the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit.
   - For a non-looping chain, the last logical channel in the chain must have the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel DMA4_CCRi[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 =
```

```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 16.4.5, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES = 32-bit (32 bpp), DMA4_CSDPi[1:0] DATA_TYPE bit field
     - Read and write port access types = maximum burst size supported by memory device, DMA4_CSDPi[8:7] SRC_BURST_EN and DMA4_CSDPi[15:14] DST_BURST_EN bit fields
     - Source and destination endianism, DMA4_CSDPi[21] SRC_ENDIAN and DMA4_CSDPi[19] DST_ENDIAN bits
     - Write mode = posted with last element nonposted, DMA4_CSDPi[17:16] WRITE_MODE bit field
     - Source and destination packed = Yes (although destination writes do not benefit because EI1), DMA4_CSDPi[6] SRC_PACKED and DMA4_CSDPi[13] DST_PACKED bits
   - DMA4_CENi: EN = 240
   - DMA4_CFNi: FN per transfer block = 160
   - DMA4_CSSAi: Source start address = 0x100000
   - DMA4_CDSAi: destination start address = 0x20013E
   - DMA4_CCRi:
     - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA4_CCRi[13:12] SRC_AMODE and DMA4_CCRi[15:14] DST_AMODE bit fields
     - Low or high priority, DMA4_CCRi[6] READ_PRIORITY bit
     - DMA request number = 0 (for software-triggered transfer), DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields
   - DMA4_CSEIi: Source EI = 1
   - DMA4_CSFIi: Source frame index = 1
   - DMA4_CDEIi: destination EI = 637
   - DMA4_CDFIi: destination frame index = 152967
2. Start the transfer through the enable bit in the channel DMA4_CCRi register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*:

```
/* Init. parameters */
DMA4-DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4-ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4-WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4-SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4-DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4-WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4-SourcePacked
      = 0x1; // DMA4_CSDPi[6]
DMA4-DestinationPacked = 0x1; //
      DMA4_CSDPi[13]
DMA4-NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4-NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
```

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

```
DMA4-SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4-DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4-SourceElementIndex = 1; // DMA4_CSEIi

DMA4-SourceFrameIndex = 1; // DMA4_CSFIi

DMA4-DestinationElementIndex = 637; // DMA4_CDEIi

DMA4-DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4-ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4-WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4-ReadPriority = 0; // DMA4_CCRi[6]
DMA4-WritePriority =
      0; // DMA4_CCRi[23]
DMA4-ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4-WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.5.8 Graphic Operations

- Transparent copy:
  1. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 1
  2. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 0
  3. Set the value of the key color in the DMA4_COLORi[15:0] COLOR_KEY bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 = ~(0x1 16);
DMA4_CCR_CH10 |= 0x1 17;

DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  1. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 1
  2. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 0
  3. Set the value of key the color in the DMA4_COLORi[15:0] SOLID_COLOR bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 = ~(0x1 17);
DMA4_CCR_CH10 |= 0x1 16;

DMA4_COLOR_CH10 = 0x00000003;
```

16.5.9 Linked-List Programming Guidelines

- With the exception of the DMA4_CCRi[7] ENABLE bit and the DMA4_CDPi[7] PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

    - DMA4_CLNK_CTRLi
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
    - DMA4_CICRi
    - DMA4_CFNi
- In case of a linked list with descriptor types 2 and 3, the content of the DMA4_CCRi register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 sDMA Register Manual

16.6.1 sDMA Instance Summary

Table 16-22. sDMA Instance Summary

Module Name	Base Address	Size
sDMA	0x4A05 6000	4KB

16.6.2 sDMA Registers

16.6.2.1 sDMA Register Summary

Index *i* represents the logical channel number (where i = 0 to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of 10 × 0x60 = 0x3C0, and thus a physical address of 0x4A05 6080 + 0x3C0 = 0x4A05 6440.

Index *j* represents the interrupt line number (where j = 0 to 3) The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of 3 × 0x4 = 0xC, and thus a physical address of 0x4A05 6008 + 0xC = 0x4A05 6014.

16.6.2.2 sDMA Register Description

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Bits	Field Name	Description	Type	Reset
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_ synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Table 16-46. DMA4_CLNK_CTRLi

Address Offset	0x0000 0084 + (0x60 * i)	**index:**	i = 0 to 31
Physical Address	0x4A05 6084 + (0x60 * i)	**Instance**	sDMA
Description	Channel Link Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ENABLE_LNK	RESERVED							NEXTLCH_ID							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0000
15	ENABLE_LNK	Enables or disable the channel linking. 0x0: Channel linking mode is disabled When set on the fly to 0 the current channel will complete the transfer and stops the chain linking 0x1: Channel linking mode is enabled. The logical channel defined in the NextLCH_ID is enabled at the end of the current transfer	RW	0
14:5	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x000

17.1 Interrupt Controllers Overview

The device provides three interrupt controller (INTC) modules, which handle interrupts at the device level:

- Cortex™-A9 microprocessor unit (MPU) subsystem interrupt controller (Cortex-A9 MPU INTC): This INTC module is a single functional unit that is integrated in the Cortex-A9 multiprocessor core alongside Cortex-A9 processors. It provides:
  - 128 hardware interrupt inputs
  - Generation of interrupts by software
  - Prioritization of interrupts
  - Masking of any interrupts
  - Distribution of the interrupts to the target Cortex-A9 processor(s)
  - Tracking the status of interrupts
  - Wake-up generator (WUGEN) module on external and local interrupts
- DSP subsystem interrupt controller (INTC): This module is a specific combination of WUGEN and the C64x+™ DSP INTC. It is used in the device but is not described in detail in this chapter. For detailed information about this module, see Chapter 5, *DSP Subsystem*.
- Cortex™-M3 MPU subsystem INTC (Cortex-M3 MPU INTC): This module is also called Nested Vectored Interrupt Controller (NVIC) and is integrated within each Cortex-M3 so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:
  - 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
  - Low-latency exception and interrupt handling
  - Prioritization and handling of exceptions
  - Control of the local power management
  - Debug accesses to the processor core
  - WUGEN module on external interrupts, coming from device peripherals

17.2 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

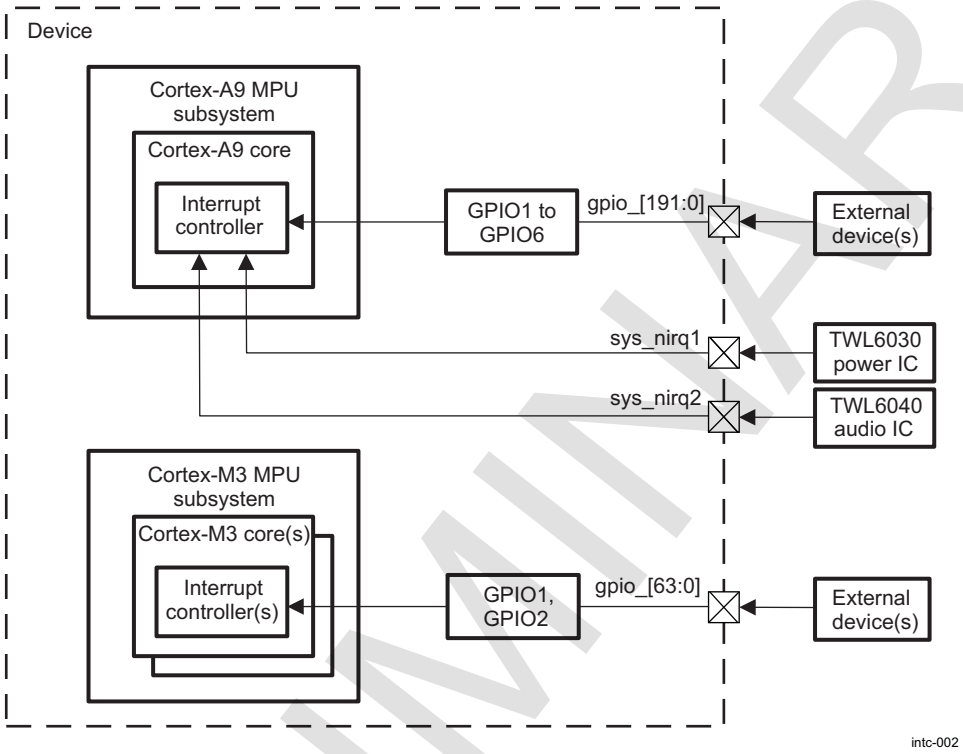

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the Cortex-A9 MPU INTC or Cortex-M3 MPU INTC.

Table 17-1. Interrupt Controllers I/O Signals

Signal Name	I/O [1]	Reset Value	Description	Cortex-A9 MPU INTC	Cortex-M3 MPU INTC
sys_nirq1	I	1	The TWL6030 power IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
sys_nirq2	I	1	The TWL6040 audio IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
gpio_[31:0]	I/O	-	External devices can use GPIO modules to generate interrupts to the Cortex-A9 MPU or Cortex-M3 MPU. There are six dedicated interrupt lines (for GPIO1 to GPIO6) to the Cortex-A9 MPU INTC and two dedicated interrupt lines (for GPIO1 and GPIO2) to the Cortex-M3 MPU INTC. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see Chapter 25, *General-Purpose Interface*.	x	x
gpio_[63:32]	I/O	-		x	x
gpio_[95:64]	I/O	-		x	-
gpio_[127:96]	I/O	-		x	-
gpio_[159:128]	I/O	-		x	-
gpio_[191:160]	I/O	-		x	-

(1) I = Input, O = Output

17.3 Interrupt Controller Integration

The Cortex-A9 MPU INTC is integrated inside the Cortex-A9 MPU core. For more information about Cortex-A9 MPU INTC integration, see Chapter 4, *Cortex-A9 MPU Subsystem Integration*.

The Cortex-M3 MPU INTC is integrated inside each Cortex-M3 MPU core. For more information about Cortex-M3 MPU INTC integration, see Chapter 7, *Dual Cortex-M3 MPU Subsystem Integration*.

17.3.1 Interrupt Mapping

NOTE: All device peripherals interrupts (external to the Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems). With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to Cortex-A9 MPU INTC

Table 17-2 lists the Cortex-A9 MPU INTC interrupt mapping.

Table 17-2. Cortex-A9 MPU INTC Interrupt Mapping

17.4 Interrupt Controllers Functional Description

17.4.1 Cortex-A9 MPU INTC Functional Description

Cortex-A9 MPU INTC is configured to have the following interrupt sources:

- Sixteen interprocessor interrupts (IPI): ID[15:0]
- Two private timer/watchdog interrupts: ID[30:29]
- Two legacy nFIQ nIRQ: one per CPU, bypasses the interrupt distributor logic and drives interrupt requests directly into the CPU, if used in legacy mode (otherwise, treated like other interrupts lines with ID28 and ID31, respectively)
- 128 hardware interrupts: ID[159:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is provided in Table 17-2, *Interrupt Requests to Cortex-A9 MPU INTC*.

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the Cortex-A9 MPU INTC, see the *ARM Cortex-A9 MP Core Technical Reference Manual* .

17.4.2 Cortex-M3 MPU INTC Functional Description

The Cortex-M3 MPU INTC has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M3 core. The interrupt mapping of these interrupts is provided in Table 17-3, *Interrupt Requests to Cortex-M3 MPU INTC*.
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M3 core within the Cortex-M3 MPU subsystem. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M3 processor level. Writing to this bit has no effect.

For more information about the functionality of the Cortex-M3 MPU INTC, see *ARM Cortex-M3 Technical Reference Manual* .

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (padconfiguration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup/down configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four different control module instances, see Section 18.3, *Control Module Integration*.

Figure 18-1 is an overview of the control module.

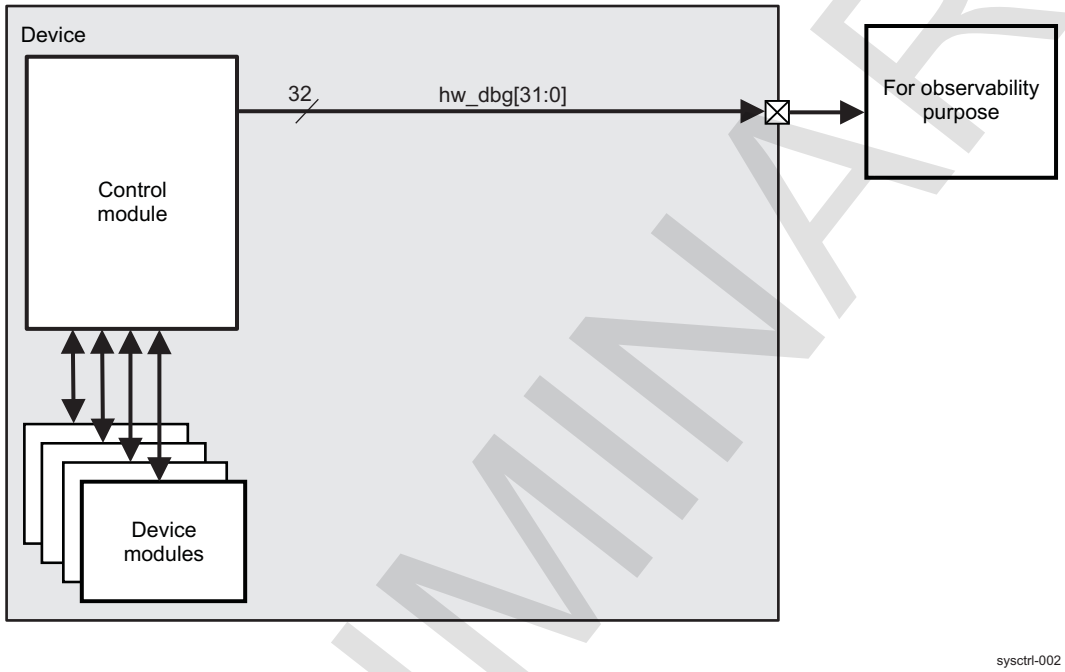
18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *PAD Functional Multiplexing and Configuration*. Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module, direct memory access (DMA) requests, and interrupts. Figure 18-2 is an overview of the control module environment.

Figure 18-2. Control Module Environment



18.2.1 Control Module Signals

Table 18-1 lists the control module hardware observability outputs configured to observe the debug signals of the device module. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

Signal	I/O [1]	Description	Reset Value [2]
hw_dbg[31:0]	O	Internal hardware observability signals 0 to 31	HiZ

(1) I = Input; O = Output
(2) HiZ = High impedance

18.3 Control Module Integration

The control module of the device is on the L4-Core interconnect. It consists of four module instances:

- General core control module (SYSCTRL_GENERAL_CORE)
- General wakeup control module (SYSCTRL_GENERAL_WKUP)
- Device core control module (SYSCTRL_PADCONF_CORE)
- Device wakeup control module (SYSCTRL_PADCONF_WKUP)

For more information about the different control module instances, see Table 18-4.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. The exception is general core control module (SYSCTRL_GENERAL_CORE) which also receives a secondary functional clock, CORE_TS_FCLK. Table 18-2 describes the signals.

Table 18-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SYSCTRL_GENERAL_WKUP	GEN_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the general core control module
	CORE_TS_FCLK	CORE_TS_FCLK	PRCM	Functional clock for the band gap state-machine instantiated in the general core control module

		Resets		
SYSCTRL_GENERAL_WKUP	GEN_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the general core control module
SYSCTRL_PADCONF_WKUP	PADCONF_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal POR affecting the device wakeup control module
SYSCTRL_PADCONF_CORE	PADCONF_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the device core control module

Table 18-3. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
SYSCTRL_GENERAL_CORE	THERMAL_ALERT	MA_IRQ_126	CORTEX-A9 INTC	Interrupt generated by general core control module to CORTEX™-A9

NOTE: For a description of the interrupt sources, see Section 17.3.2,*Interrupt Requests to the Cortex-A9 MPU Interrupt Controller*.

The control module is reset by the internal POR, which is active low. The PRCM module provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to both of the core control module instances, and a nonretention POR signal (WKUP_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see , *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*. The control module does not respond to a warm reset or to an L4-Core reset.

The main sequential logic within the system control module is accessible in a register file through the L4-Core interconnect. The PRCM module provides the CFG_L4_ICLK functional clock signal (L4_CFG clock domain) separately to each of the two core control submodules. In addition, an instantiated inside the general core control, the band gap state-machine receives its functional clock (CORE_TS_FCLK) from the PRCM module. For more information about this signal, see , *CM2 Clock Generator* in Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2011, Texas Instruments Incorporated

The PRCM module also supplies the WKUP_L4_ICLK2 functional clock signal (L4_WKUP clock domain) to each of the two wake-up control module instances. For more information about this signal, see , *PRM Clock Source* in Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module latches the sys_boot[7:0] pad signals at POR and exports them as vector to the SYSBOOT[7:0] input of the general core control module. It is scanned in the CONTROL_STATUS[7:0] SYS_BOOT bit field. For more information, see Section 27.2.4.2, *Booting Device Order Selection*, and Section 27.2.4.1, *Clock Source Selection.*

The thermal management subsystem inside the general core control module delivers one interrupt request (THERMAL_ALERT) to line MA_IRQ_126 of the MPU subsystem interrupt controller (INTC) (Cortex-A9 INTC), and delivers a thermal protection output signal (TSHUT) to the GPIO3 instance. For more information about the functional outputs of the thermal management control module, see Section 18.4.10.

The signal integration of the control module features:

- No IDLE hardware handshake
- No STANDBY hardware handshake
- No SAVE and RESTORE hardware handshake
- No wake-up request generation
- No DMA request generation
- One interrupt request (IRQ) – THERMAL_ALERT to the MPU subsystem
- A thermal shutdown protection signal (TSHUT) delivered to a GPIO3 input.
- Three functional clocks: two clocks in the CFG and one in the WKUP clock domains
- One retention and one nonretention internal power-on-based resets

Figure 18-3 shows the integration of the module in the device.

18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

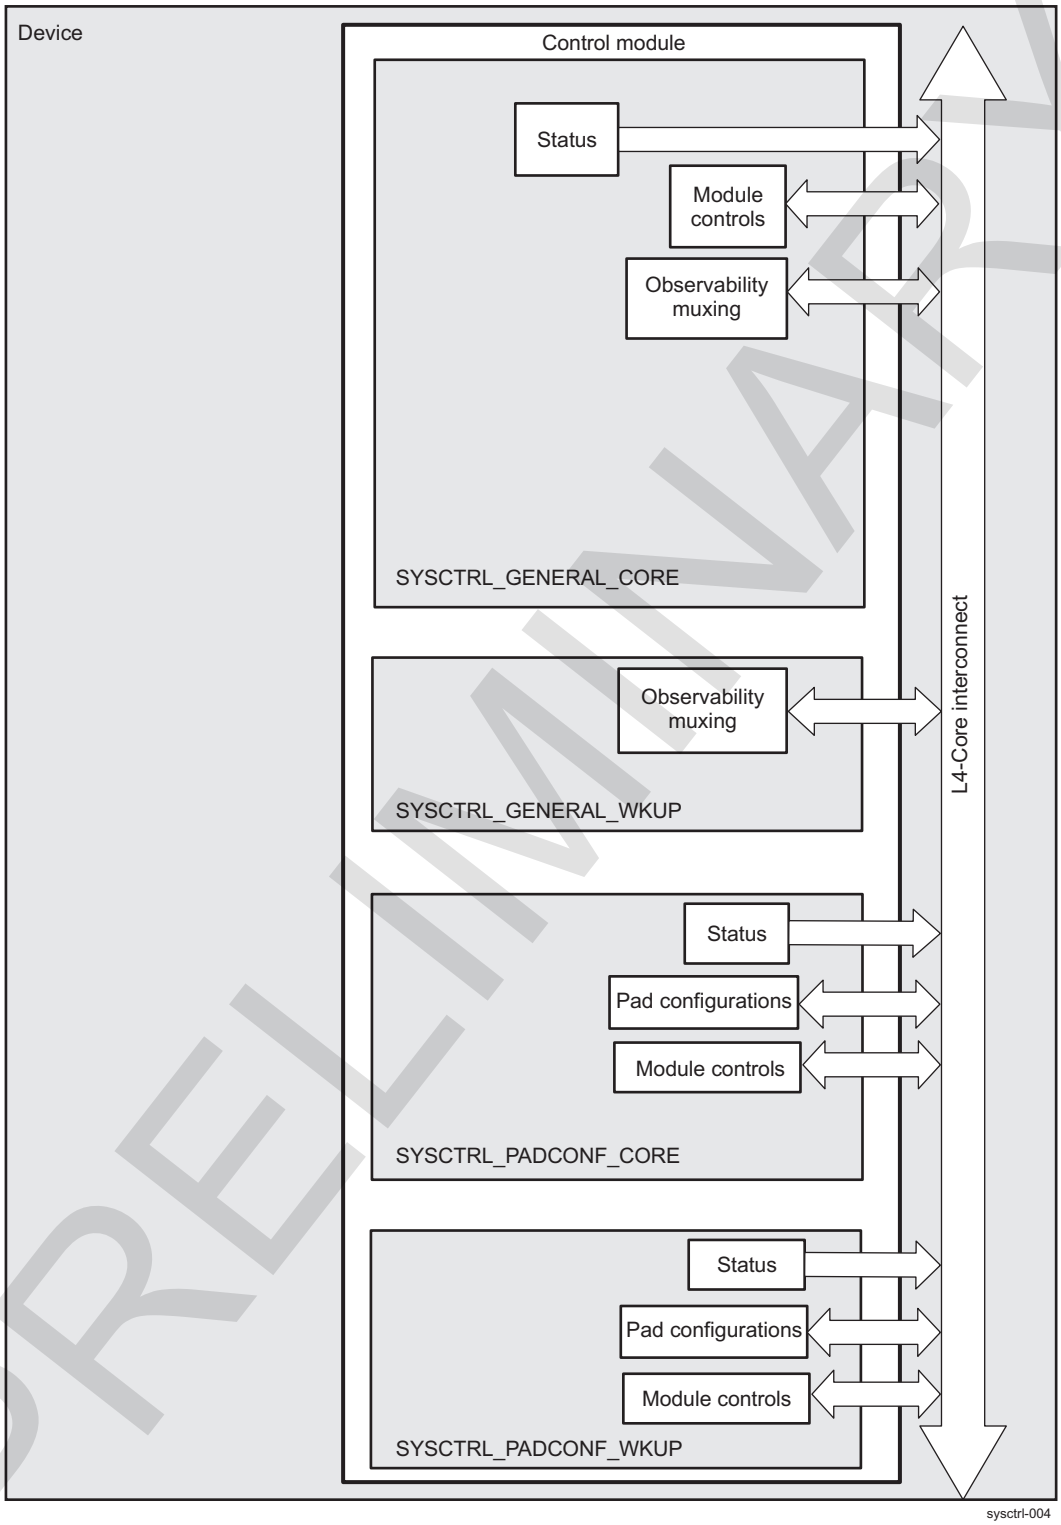
The control module controls the settings of various device modules through the register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pins configured for hardware observability.

Figure 18-4 is the control module block diagram.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 18-4. Control Module Block Diagram



The control submodules primarily implement a bank of registers accessible (read/write) by software and some read-only registers that provide status information.

The read/write registers in the general control module can be divided into the following classes:

- Hardware observability registers (32-bit read/write registers)

Copyright © 2011, Texas Instruments Incorporated

- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

The read/write registers in the device(padconfiguration) control module can be divided into the following classes:

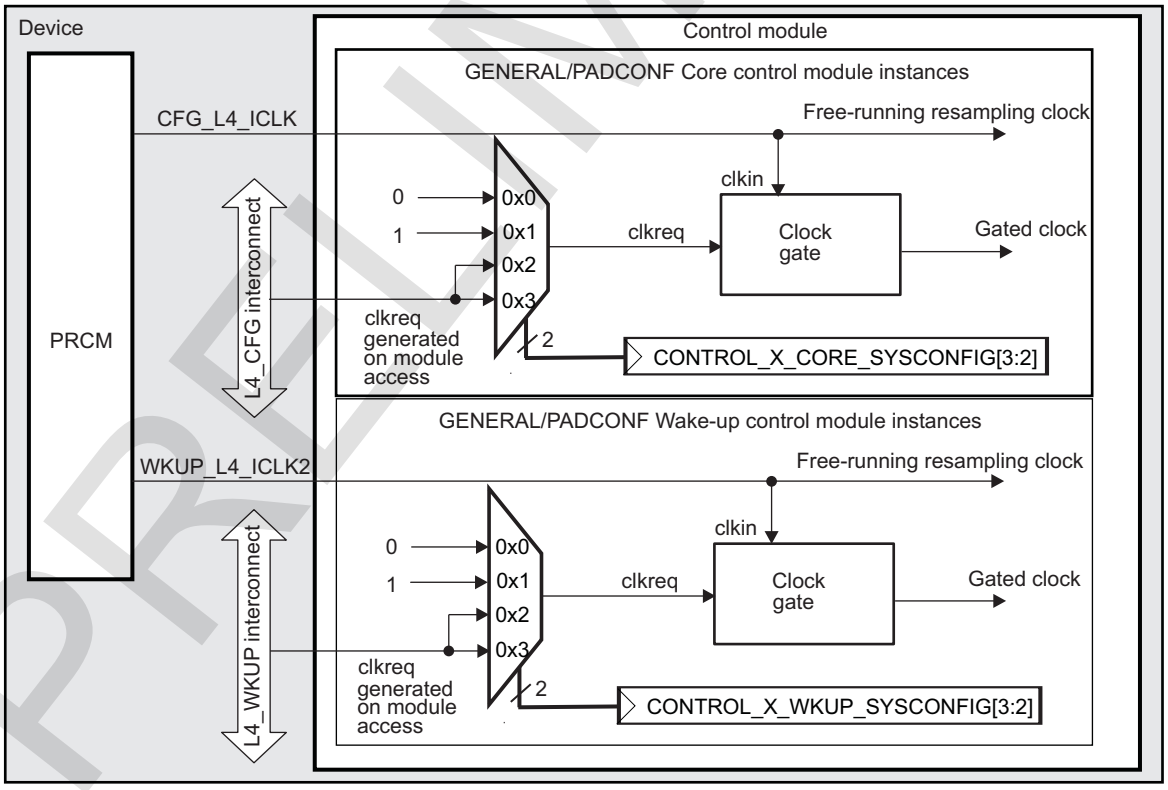
- Pad configuration registers (32-bit registers, one register for two pads)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

Figure 18-5 shows the distribution schema of the control module internal clock . Each CFG_L4_ICLK and WKUP_L4_ICLK2 source clock is internally distributed into two clock paths: the first path directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path can be internally gated within the module.

The CORE_TS_FCLK clock, which drives the general core control band gap state-machine, can also be locally gated through a dedicated bit in the CONTROL_TEMP_SENSOR register. For more information about the temperature module off mode, see Section 18.4.10, *Band Gap Voltage and Temperature Sensor*.

Figure 18-5. Control Module Internal Clock Paths



PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

The clock-gating strategy for L4 clocks is selected through the CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE bit field available in each of the four control module instances. Table 18-5 describes the different possibilities for clock management. There are no PRCM software controls for the CFG_L4_ICLK and WKUP_L4_ICLK2 clocks in the control module. There are, however, clock activity status bits in the PRCM module.

The CORE_TS_FCLK has the following software controls: enable, status, and divider ratio, in the PRCM module. See , *Clock Domain Modes*, and , *CD_WKUP Clock Domain* , in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-5. Internal Clock Gating Options

Feature	CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE Value	Description
Local clock control	0b00	Clock is manually gated.
Local clock control	0b01	Clock is manually enabled.
Local clock autogating	0b10, 0b11	Clock is automatically gated when there is no access to the control module through the L4-interconnect.

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The general core module and device core control module instances are fully built with retention flip-flops (RFFs) and are powered in the CORE power domain; thus, they can be in active or retention mode. The core instances lose their content when the CORE power domain is in off mode. In contrast to the core control instances, the control wake-up instances are always powered and active. For more information about the device low-power states, see, *Device Low-Power States*, in Chapter 3, *Power, Reset, and Clock Management*.

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.4.3 Save-and-Restore Mechanism

The control core module instances lose their contents when the CORE power domain is in off mode. To prevent this, before going to off mode, the core register context is copied by software into a dedicated SAR_RAM in the WKUP voltage domain. The save-and- restore (SAR) mechanism, controlled by the PRCM module, allows restoring registers to the value present before going to off mode. Thus, core domain registers have a correct configuration/state immediately after the core power is on again without requesting a software operation to reconfigure them.

Because the SAR mechanism is managed by software-accessible registers, no hardware-specific requirements exist. For more information about SAR, see , *Device Off State Management.*, in Chapter 3, *Power, Reset, and Clock Management*.

18.4.5 Hardware Requests

The control module does not generate DMA or wake-up requests. The general core control module generates one IRQ (THERMAL_ALERT) to the Cortex-A9 INTC (MA_IRQ_126 line). For more information, see Section 17.3.2, *Interrupt Requests to the Cortex-A9 MPU Interrupt Controller*.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power-on, reset values for the registers define the *safe state* for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and outputs pads are turned off. After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see Chapter 27, *Initialization*.

General-purpose (GP) devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

The CONTROL_STATUS[7:0] SYS_BOOT boot field reflects the state of the sys_boot pins captured at POR in the PRCM module.

18.4.7 General Control Module Instances

18.4.7.1 General Core Control Module Instance

The SYSCTRL_GENERAL_CORE instance contains most of the control logic that provides the hardware observability features for different digital phase-locked loop (DPLL) clockout and DPLL-specific signals, DMA requests , IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, and some peripheral control and status registers are also mapped there.

The register sets available within the SYSCTRL_GENERAL_CORE are:

- Observability control registers:
  - CONTROL_HWOBS_CONTROL
  - CONTROL_DEBOBS_FINAL_MUX_SEL
  - CONTROL_CONF_SDMA_REQ_SELx
  - CONTROL_CONF_CLK_SELx (where x = 0 to 2)
  - CONTROL_CONF_DPLL_X_SEL (where X = FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
- Part of the debug view channel selection registers: CONTROL_CORE_CONF_DEBUG_SEL_TST_X
- MMU address translation-related registers: CONTROL_CORTEX_M3_MMUADDRTRANSLTR and CONTROL_CORTEX_M3_MMUADDRLOGICTR
- Standard fuse registers: CONTROL_STD_FUSE_X
- Clock gating configuration register: CONTROL_GEN_CORE_SYSCONFIG
- Control status register: CONTROL_STATUS
- Peripheral control registers:
  - CONTROL_TEMP_SENSOR
  - CONTROL_BANDGAP_CTRL
  - CONTROL_BANDGAP_COUNTER
  - CONTROL_BANDGAP_THRESHOLD
  - CONTROL_TSHUT_THRESHOLD
  - CONTROL_BANDGAP_STATUS
  - CONTROL_DSS_CONTROL
  - CONTROL_USBOTGHS_CONTROL
  - CONTROL_LDOSRAM_MPU_VOLTAGE_CTRL
  - Etc.

18.4.7.2 General Wakeup Control Module Instance

The registers associated with this module are:

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

- Clock gating configuration register: CONTROL_GEN_WKUP_SYSCONFIG
- Register with spare bits: CONTROL_OCPREG_SPARE
- Part of the debug view channel selection registers: CONTROL_WKUP_CONF_DEBUG_SEL_TST_X

18.4.7.3 Device Core Control Module Instance

The SYSCTRL_PADCONF_CORE instance provides the device-specific pad control features, such as pullup/down I/O configuration and pad functional multiplexing. Wake-up control/status features are also subjects of the device core control.

The registers associated with this module are:

- Clock gating configuration register: CONTROL_PADCONF_CORE_SYSCONFIG
- Different peripheral pad mode configuration and wake-up status/configuration registers:
  - CONTROL_CORE_PAD0_X_PAD1_Y
  - CONTROL_PADCONF_WAKEUPEVENTx
  - CONTROL_PADCONF_GLOBAL
  - CONTROL_SMARTxIO
  - CONTROL_C2CIO_PADCONF_0
  - Etc.
- Peripheral pad voltage-level control register: CONTROL_PADCONF_MODE
- Miscellaneous controls for different device interface modules: CONTROL_X registers, such as the CONTROL_EMIF register (including the CONTROL_EFUSE registers)

18.4.7.4 Device Wake-Up Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the WKUP device control module. The registers instantiated are:

- Clock gating configuration register: CONTROL_PADCONF_WKUP_SYSCONFIG
- CONTROL_WKUP_PAD0_X_PAD1_Y registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations

NOTE: SYSCTRL_PADCONF_X alias notifies a device control module instance.

Table 18-110 shows the memory size and base addresses assigned to the different control module instances

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or a group of pads. Each configurable pin has its own configuration register for pullup/down control and for assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers (CONTROL_CORE_PAD0_X_PAD1_Y) configures the pads in the CORE power domain. The second set of registers (CONTROL_WKUP_PAD0_X_PAD1_Y) configures the pads in the WKUP power domain.

The pad configuration as defined in this module is used in the IO_CTRL logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO_CTRL logic and driven by the state and/or logic of the internal device.

The gating feature allows forcing an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state or value to be set on the pad when the logic equation is "True."

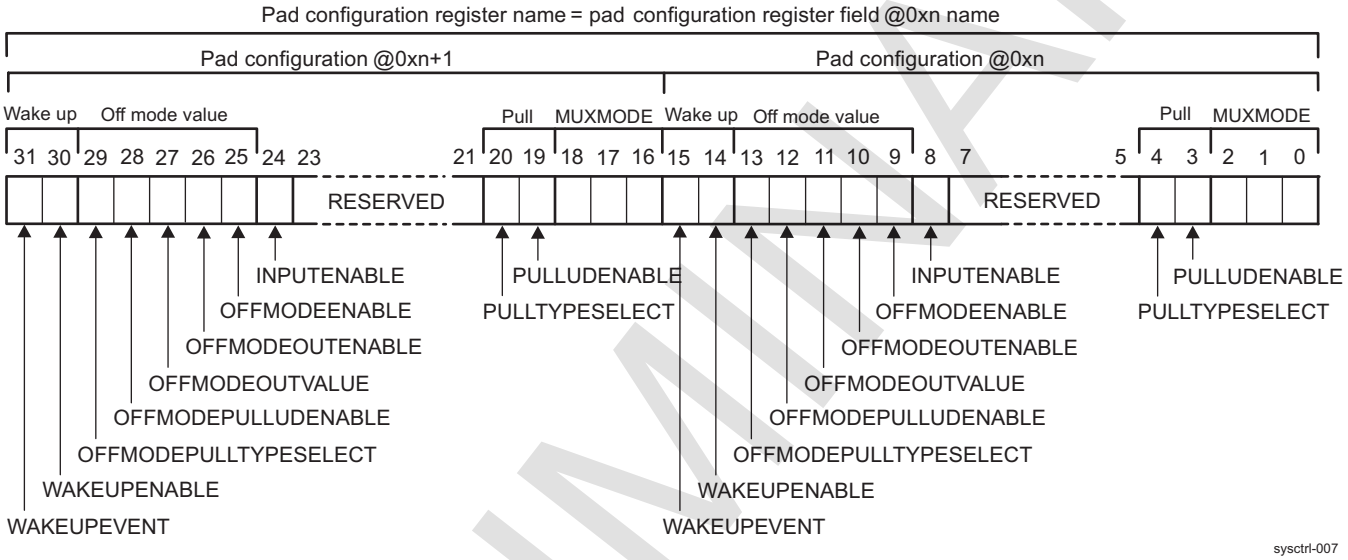
Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The protection feature provides control on each input line of the control module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad_x.MuxMod selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16 least-significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); thus, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. Figure 18-6 shows the 16-bit-wide pad configuration register field associated with each pin.

Figure 18-6. Pad Configuration Register Functionality



NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the function mapped on the pin with seven (0 to 6) possible functional modes for each pin.
- PULL (2 bits) for combinational pullup/down configuration:
  - PULLTYPESELECT: Pullup/down type selection for the pin
  - PULLUDENABLE: Enables pullup/down feature for the pin
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
  - INPUTENABLE = 0: Input disable. Pin is configured only in output mode.
  - INPUTENABLE = 1: Input enable. Pin is configured in bidirectional mode.
- Off mode values (1 bit) override the pin state when the OFFMODEENABLE bit in CONTROL_CORE_PAD0_X_PAD1_Y is set and off mode is active. This feature allows having separate configurations (5 bits) for the pins when in off mode:
  - OFFMODEENABLE: Off mode pin state override control. Set to 1 to enable the feature and set to 0 to disable it.
  - OFFMODEOUTENABLE: Off mode output enable value. Set to 0 to enable the feature and set to 1 to disable it.
  - OFFMODEOUTVALUE: Off mode output value.
  - OFFMODEPULLUDENABLE: Off mode pullup/down feature enable
  - OFFMODEPULLTYPESELECT: Off mode pullup/down type selection

PRELIMINARY

- Wake-up bits (2 bits):
  - WAKEUPENABLE: Enable wake-up detection on input. It is also the off mode input enable value.
  - WAKEUPEVENT: Wake-up event status for the pin

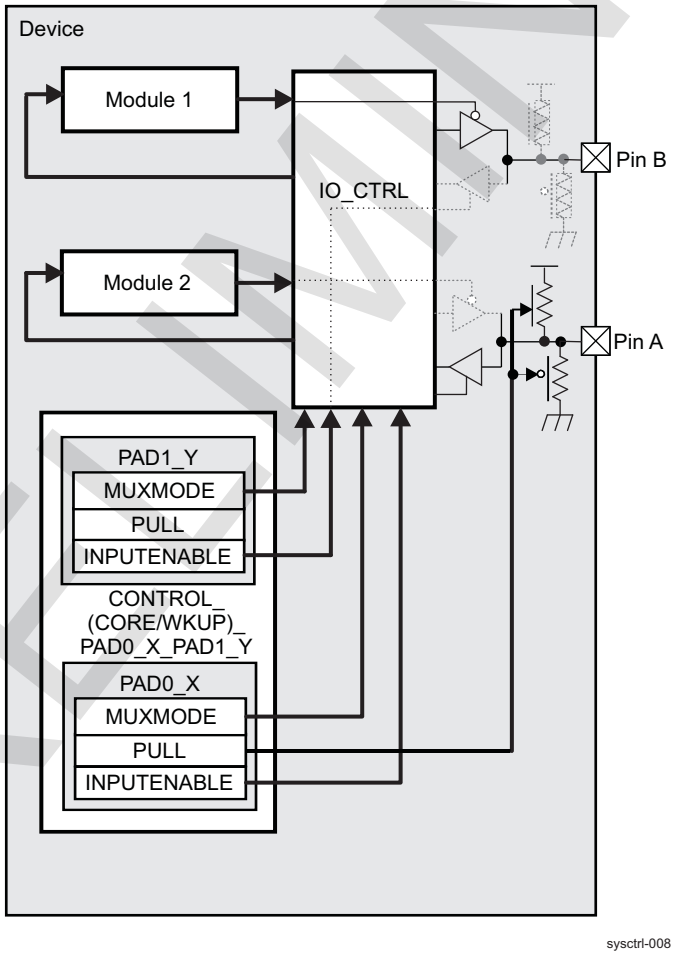
CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

NOTE: Because off-mode affects pads only in the CORE power domain, OFFMODE-related bits are not present in the pad configuration registers of the WKUP power domain .

Figure 18-7 shows the pad configuration functionality when off mode is inactive. For more information about off mode, see Section 18.4.8.4, *Off Mode PAD Control Overview*.

Figure 18-7. Pad Configuration Diagram



The I/O pads are controlled by software by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup/down configuration
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration

Copyright © 2011, Texas Instruments Incorporated

For more information about how to configure the I/O pads, see Section 18.5.1.2.5, *Pad Configuration Programming Points*.

For more information about the GPIO module, see Section 25.4.8, *General-Purpose Interface Data Input/Output Capabilities.*

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- HSUSB HOST
- McPDM

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and GPIOi.GPIO_OE registers must be written.

NOTE: Software INPUTENABLE controls are not available for the lpddr21_x, lpddr22_x, usbb1_hsic_x, and usbb2_hsic_x pads. Once their buffers are enabled they are always bidirectional. For more information, see Section 18.4.12.9.2, *High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings*.

Table 18-6 lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-6. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal is inactive.	Input enable signal is active.
OFFMODEENABLE	Off mode values are invalid.	Off mode values are valid.
OFFMODEOUTENABLE	Output	Input
OFFMODEOUTVALUE	Low	High
OFFMODEPULLUDENABLE	Not activated	Activated
OFFMODEPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event is not detected.	Wake-up event is detected.
MUXMODE bits	See Table 18-7, *Mode Selection*.	See Table 18-7, *Mode Selection*.

18.4.8.1 Mode Selection

Table 18-7 lists the multiplexing modes and settings.

Table 18-7. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

Table 18-7. Mode Selection (continued)

MUXMODE	Selected Mode
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Modes 1–6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

Safe mode (Mode 7) avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. Safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pin multiplexing, the pad is actually set undriven (HiZ) with potential pullup/down.

For more information about the configurable mode on each pin, see Table 18-10 and Table 18-9.

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown/pullup resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-8. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

For more information about the pull available on each pin, see Table 18-10 and Table 18-9.

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the CONTROL_LPDDR2IO1_0 through CONTROL_LPDDR2IO1_2 and CONTROL_LPDDR2IO2_0 through CONTROL_LPDDR2IO2_2 registers, respectively.

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x and usbb2_hsic_x pads are available in the CONTROL_USBB_HSIC register.

For more information, see Section 18.4.12.9.2, *High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings*.

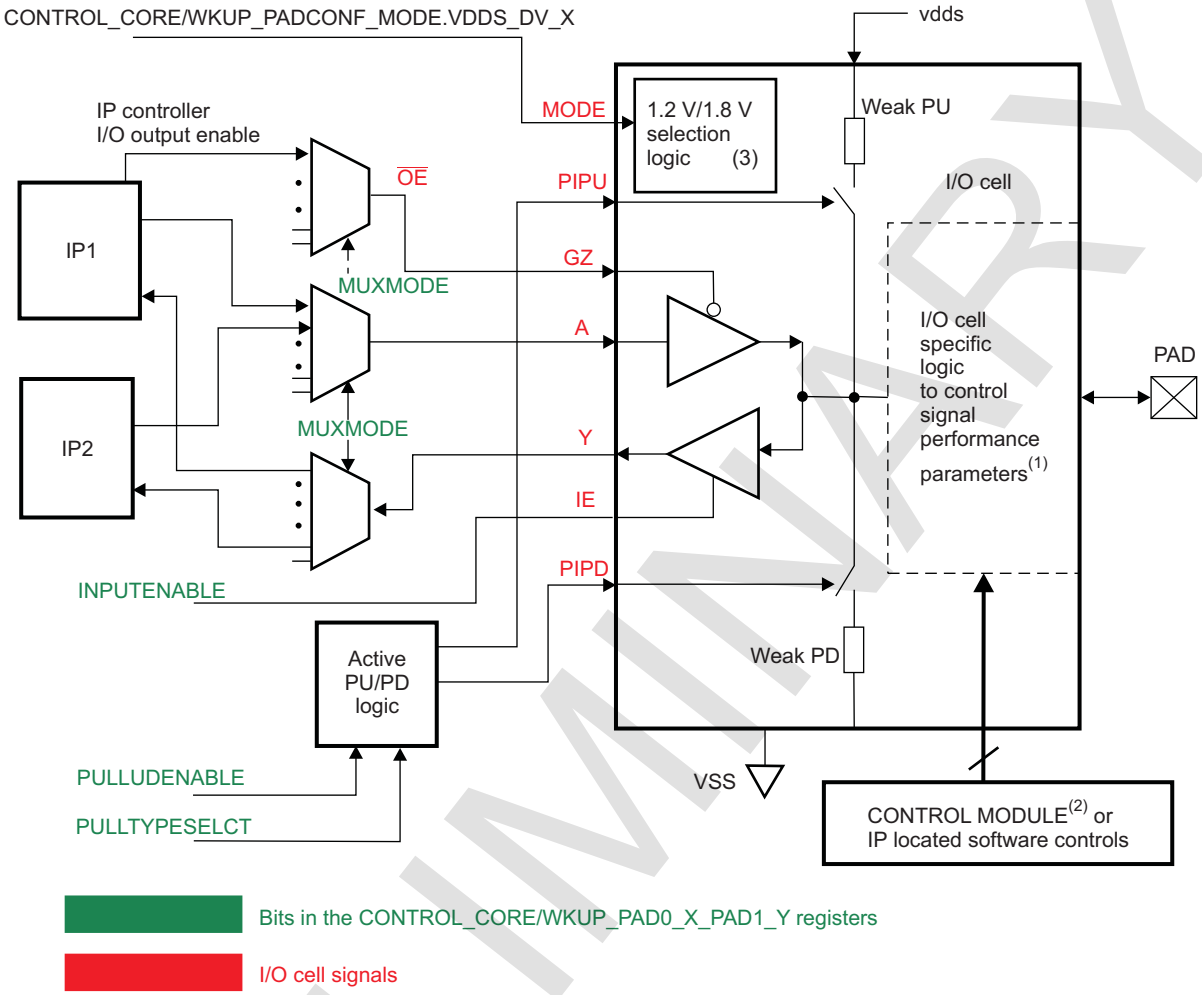
18.4.8.2.1 Generic Pad Configuration Bit Fields vs I/O Cell Mapping

Figure 18-8 provides a generic view of the relations between the pad configuration controls and I/O cell functions for a pad configured in active mode.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 18-8. Active Mode Pad Configuration Bit Fields vs I/O Cell Mapping



(1) Section 18.4.12.9, *Signal Integrity Parameter Control Registers With Pad Group Assignment*, summarizes the I/O cell signal performance settings. For more information about the controlled I/O cell electrical parameters and interdependency considerations, see the device data manual.

(2) For information about the mapping of software controls in the control module versus different device pads, see Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*. For more information about interface-specific signal parameter settings, see the device data manual.

(3) The CONTROL_CORE/WKUP_PADCONF_MODE.VDDS_DV_x bit is available for each I/O that is part of the dual-voltage domain group x. For more information about 1.2-V/1.8-V dual-voltage domain I/Os, see the device data manual. For more information about peripheral dual-voltage software controls versus pad group mapping, see Section 18.4.12.10, *Dual-Voltage-Supplied Peripheral Controls*.

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-10 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default padconfiguration settings (POR values) for pads in the CORE power domain, seeSection 18.6.7, *SYSCTRL_PADCONF_CORE Register Description;* for pads in the WKUP power domain, see Section 18.6.9, *SYSCTRL_PADCONF_WKUP Register Description.*

Copyright © 2011, Texas Instruments Incorporated

NOTE:

- Table 18-9 lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. Table 18-10 lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
- In Table 18-10 and Table 18-9, an empty cell indicates that the mode or pull is not available for this pin.

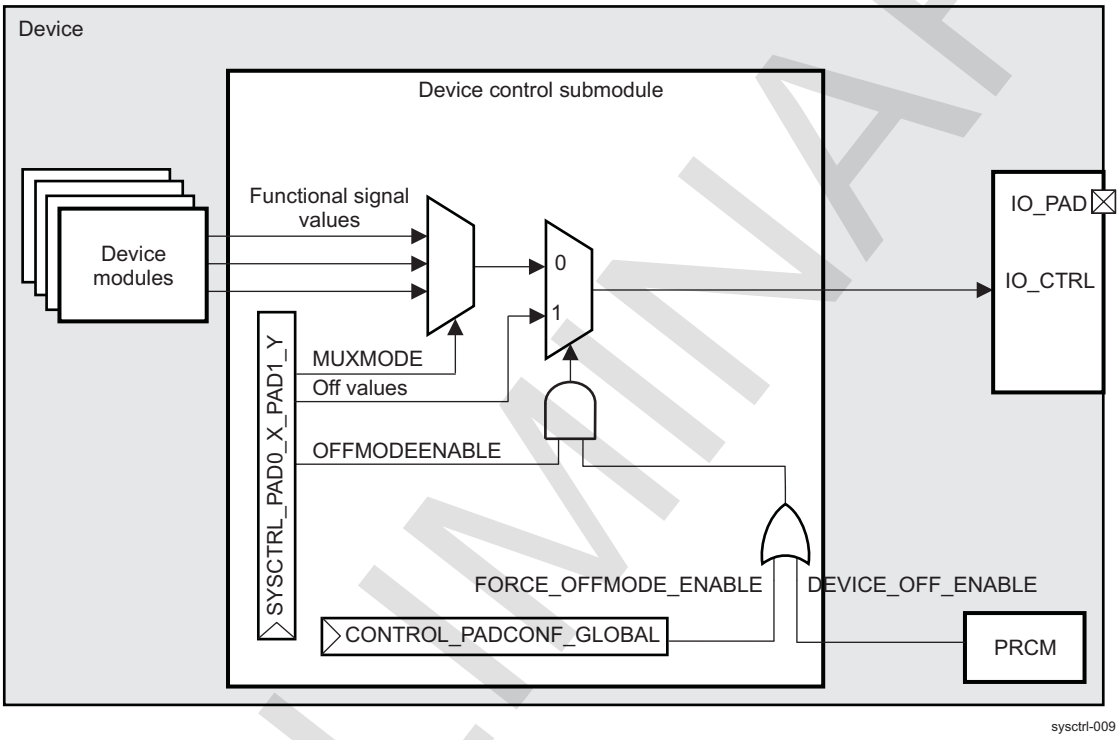
18.4.8.4 Off Mode Pad Control Overview

When off mode is selected, which is true when PRM_DEVICE_OFF_CTRL[0] DEVICE_OFF_ENABLE from the PRCM module = 0b1 or CONTROL_PADCONF_GLOBAL[31] FORCE_OFFMODE_ENABLE = 0b1 (force bit to test the value of off mode), the off mode values field CONTROL_CORE_PAD0_X_PAD1_Y[27,11] OFFMODEOUTVALUE overrides the pad state when the CONTROL_CORE_PAD0_X_PAD1_Y[25,9] OFFMODEENABLE bit is set.

The CONTROL_CORE_PAD0_X_PAD1_Y[26,10] OFFMODEOUTENABLE bit is active low.

Figure 18-9 shows the off mode pad control.

Figure 18-9. Off Mode Pad Control Overview



If off mode is active and the OFFMODEENABLE bit field is set to 0 (disable the off mode override feature), the pad keeps the AND value of the configuration (input/output, pullup/down) it had before going into off mode:

- For an input, the pad is isolated and the pull remains active.
- For an output, the value is latched before going into off mode, to drive the same value in off mode.

NOTE: Software controls for internal off-mode pullups and pulldowns on the usbb1_hsic_x and usbb2_hsic_x pads are available in the CONTROL_USBB_HSIC register.

No internal off-mode pullups and pulldowns are available for the lpddr21_x and lpddr22_x pads of the device.

For more information, see Section 18.4.12.9.2, *High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings*.

18.4.8.4.1 Wake-Up Event Detection

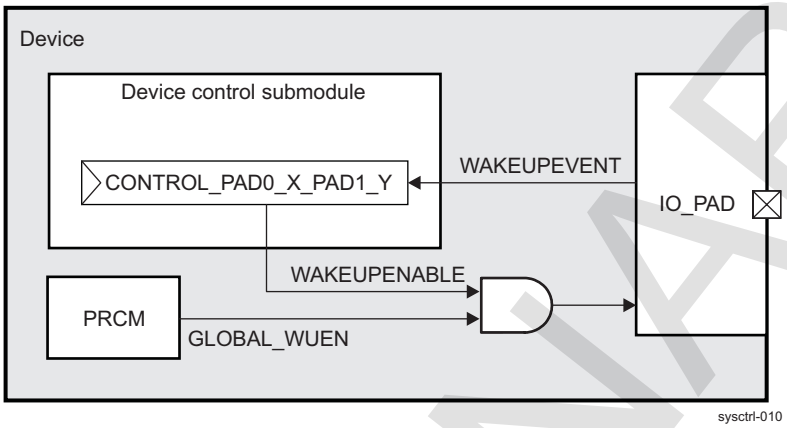
In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] WAKEUPEVENT bits.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The off mode I/O pads wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from the PRCM module. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each I/O pad of the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-10. Wake-Up Event Detection Overview



NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

If this pin is configured as an output in active mode, the off override function must be enabled to set the pin as an input during off mode: in the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y register, set the OFFMODEENABLE bit to 0x1 to enable the off override function and set the OFFMODEOUTENABLE bit to 0x1 to switch this pin to input mode.

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup/down resistors at the pad to avoid spurious wake-up detection. User software can optionally enable the pad off-mode internal pullup/down resistors through the appropriate setting of the OFFMODEPULLUDENABLE and OFFMODEPULLTYPESELECT bits in the corresponding pad configuration register.

The CONTROL_PADCONF_WAKEUPEVENT_0 through CONTROL_PADCONF_WAKEUPEVENT_6 registers are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these seven additional registers helps reduce the software latency in identifying which pad has triggered a wake-up event.

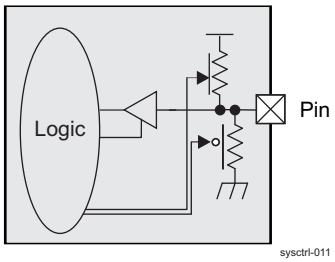
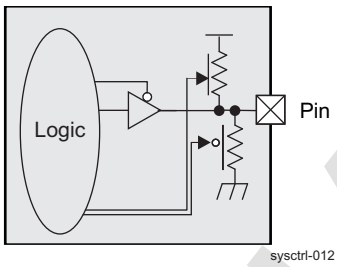
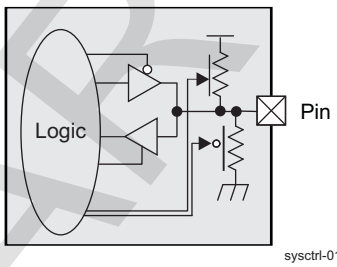
18.4.8.4.2 I/O Power Optimization

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. Table 18-11 shows the three available pin (or ball) types.

Table 18-11. Pin Types

Input	Output	Bidirectional
		






The configuration differs according to the I/O cell types. The following advice can be useful to avoid extra current leakage:

- For input pins, use a pullup/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

NOTE: If the pad is always configured in output mode, it is recommended for software to disable the internal pull by programming the I/O pad configuration register of the corresponding control module.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding pad configuration bit CONTROL_CORE /WKUP_PAD0_X_PAD1_Y.INPUTENABLE set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

Figure 18-11 shows how to optimize the power consumption of pads.

PRELIMINARY

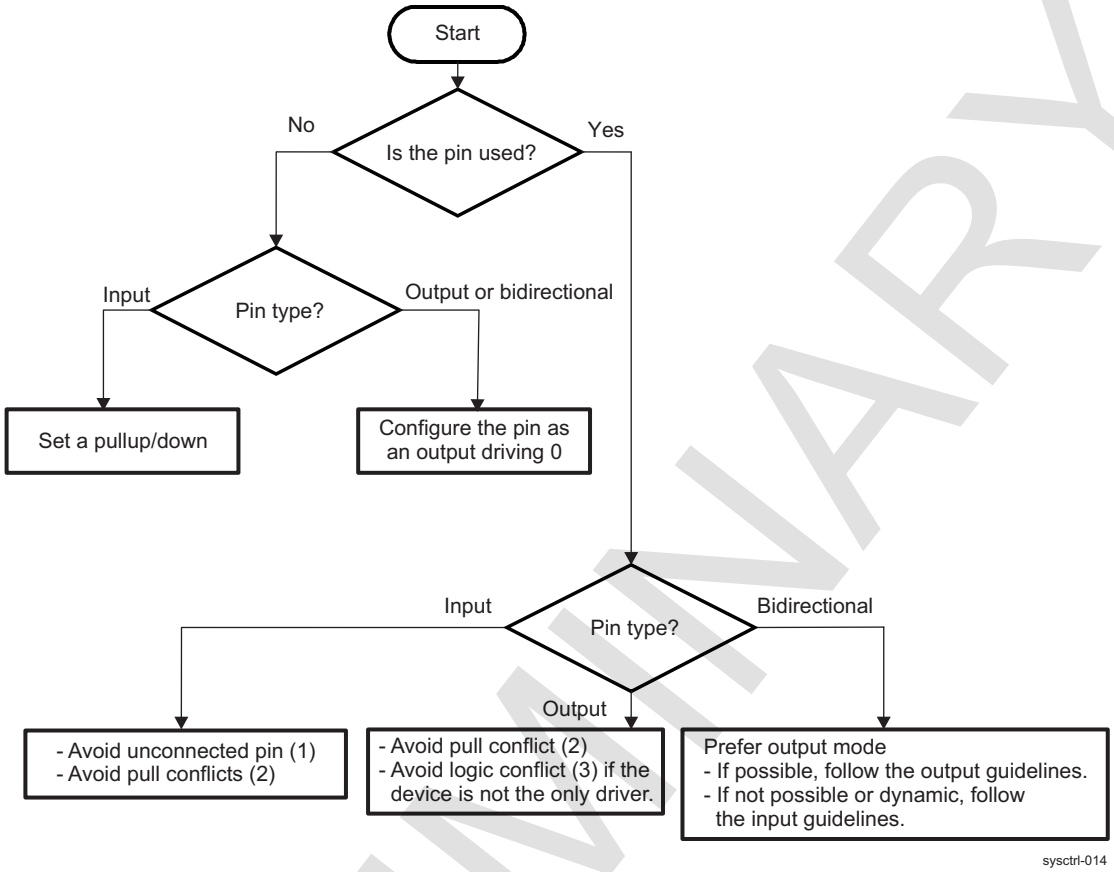
Figure 18-11. I/O Power Optimization Flow Chart



The following notes explain more about the pin configuration.

- To avoid unconnected pins, the configuration depends on its use:
  - If the pin is not driven externally, a pullup/down is required.
  - Otherwise, a pullup/down is not necessary.
- Pull conflicts occur when different pulls are on the same line. To configure the pin correctly, avoid having external and internal pulls together.
- Logic conflicts consist in different electrical levels at the same time on the same line. This can occur when several devices are connected to the same line. The two possible cases are:
  - If no external device drives the line, configure the pin to drive 0.
  - If another device drives the line, the same value must be driven or the pin must be disconnected (high-impedance state [HiZ]).

NOTE: It is advised to use HiZ logical state on the device or on the external component when the line is driven by both components.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device primarily supports 1.8-V I/O voltage on its interfaces, with the exception of the MMC/SD/SDIO1 interface, which supports 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on the MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell MMC1_PBIAS to provide a 1.8-V or 3.0-V reference.

A second PBIAS cell (PBIAS1) is integrated in the device. One of its associated extended-drain I/O cells operates the signals of the gpio_wk0 through gpio_wk2 I/Os.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

A separate extended-drain I/O cell (USBC1_ICUSB extended-drain I/O cell) is shared between usbc1_icusb_dp and usbc1_icusb_dm (MUXMODE = 0x0), and between the gpio98 and gpio99 (MUXMODE = 0x3) pads. The USBC1_ICUSB I/O cell and the gpiowk_0–gpiowk_2 extended-drain I/O cells are biased by the same PBIAS1 output voltage.

NOTE: With the appropriate PBIAS cell configuration, the different I/Os muxed on the sdmmc1, usbc1_icusb, and gpio_wk0 through gpio_wk2 pads can operate at 1.8-V or 3.0-V power supply.

The MMC1_PBIAS cell and its associated MMC1 extended-drain I/O is software-controlled by bits in the CONTROL_PBIASLITE and CONTROL_MMC1 registers of the device core control module. PBIAS1 and associated GPIO_WKx and USBC1_ICUSB_x I/Os are software-controlled by bits in the CONTROL_PBIASLITE, CONTROL_MMC1, and CONTROL_GPIOWK registers.

Figure 18-12 shows the functional block diagram with the connections between the PBIAS cells and the extended-drain I/O cells.

Figure 18-12. Functional Block Diagram

Table 18-12. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Description
MMC1_PBIAS_PWRDNZ	Protects the MMC1_PBIAS cell when the SDMMC1_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is set to 0, the PBIAS output voltage is equal to SDMMC1_VDDS voltage and the PBIAS supply detector is disabled.
MMC1_PBIAS_VMODE	Sets the SDMMC1_VDDS voltage level (MMC1_PBIAS side) according to which MMC1_PBIAS cell generates appropriate biasing levels for the MMC1 extended-drain I/O. The default state of this bit is HIGH, indicating that the voltage level SDMMC1_VDDS is 3.0 V.
MMC1_PBIAS_HIZ_MODE	When MMC1_PBIAS_HIZ_MODE is set to 1, the PBIAS output is in high impedance. MMC1_PBIAS_ERROR is automatically set to 1 when MMC1_PBIAS_HIZ_MODE = 1. When MMC1_PBIAS_HIZ_MODE = 0, MMC1_PBIAS cell is in normal operation mode.
MMC1_PBIAS_SUPPLY_HIGH_OUT	Output from the internal MMC1_PBIAS voltage supply detector, which indicates whether the SDMMC1_VDDS supply is 3.0 V or 1.8 V
MMC1_PBIAS_ERROR	Indicates whether the software-programmed MMC1_PBIAS_VMODE level matches the MMC1_PBIAS_SUPPLY_HI_OUT output signal during normal operation
MMC1_IO_PWRDNZ	Protects the MMC1 I/O extended-drain cell when the SDMMC1_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDMMC1_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
SDMMC1_DRx_SPEEDCTRL, x = (0…2)	Speed control signals for three different SDMMC1 pad groups identified within the MMC1 I/O cell
SDMMC1_PUSTRENGTH_GRPx, x = (0…3)	Pullup strength controls for four different SDMMC1 pad groups identified within the MMC1 I/O cell
PBIAS1_PWRDNZ	Protects the PBIAS1 cell when the SIM_VDDS supply voltage is not stable. Software must keep the PWRDNZ signal to 0b0 whenever this supply voltage ramps up/down or changes. When this bit is at 0, the PBIAS1 output voltage is equal to SIM_VDDS voltage and the PBIAS supply detector is disabled.
PBIAS1_VMODE	Sets the SIM_VDDS voltage level (PBIAS1 side) according to which PBIAS1 cell generates appropriate biasing levels for the GPIOWK0GPIOWK2 and USBC1_ICUSB associated extended-drain I/Os. The default state of this bit is HIGH, indicating that the voltage level SIM_VDDS is 3.0 V.
PBIAS1_HIZ_MODE	When PBIAS1_HIZ_MODE is set to 1, the PBIAS1 output is in HIGH impedance. PBIAS1_ERROR is automatically set to 1 when PBIAS1_HIZ_MODE = 1. When PBIAS1_HIZ_MODE = 0, PBIAS1 is in normal operation mode.
PBIAS1_SUPPLY_HIGH_OUT	Output from the internal PBIAS1 voltage supply detector, which indicates whether the SIM_VDDS supply is 3.0 V or 1.8 V
PBIAS1_ERROR	Indicates whether the software-programmed PBIAS1_VMODE level matches the PBIAS1_SUPPLY_HI_OUT output signal during normal operation
GPIOWK_IO_PWRDNZ	Protects the GPIOWK0GPIOWK2 associated extended-drain I/O cell when the SIM_VDDS voltage is not stable Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is set to 0, the pad is floating.
PAD_GPIO_WK1_LOW	This signal must be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk1 pad. This is to ensure normal use of the gpio_wk1 pad.
0.22 PAD_GPIO_WK2_LOW	This signal must be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk2 pad. This is to ensure normal use of the gpio_wk2 pad.
0.23 USBC1_ICUSB_IO_PWRDNZ	Protects the USBC1_ICUSB extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
0.24 USBC1_DR0_SPEEDCTRL	Speed controls for the ICUSB pads associated with the USBC1_ICUSB associated I/O cell

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

NOTE: When HIZ_MODE = 1, the PBIAS output (the pbias_mmc1 pin) must be tied to a defined external potential to avoid stress on transistors.

Table 18-13 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-13. Power Supplies

Name	Description
VDD2	Core voltage supply
SDMMC1_VDDS	MMC1 I/O cell supply voltage nominal 1.8 V/3.0 V
SIM_VDDS	USBC1_ICUSB and GPIOWK I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

18.4.9.1 PBIAS Cell

The MMC1_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended-drain in the MMC/SD/SDIO1 cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SDMMC1_VDDS) value (1.8 V or 3.0 V) and update, with its status, the CONTROL_PBIASLITE[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit. However, this is possible when the voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the MMC1_PBIAS_PWRDNZ signal is set to 0b1).

The PBIAS1 cell provides a reference voltage for biasing the gpiowk0gpiowk2 associated extended-drain I/O cell and the USBC1_ICUSB extended-drain I/O cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SIM_VDDS) value (1.8 V or 3.0 V) and update, with its status, the CONTROL_PBIASLITE[30] PBIASLITE1_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the PBIAS1_PWRDNZ signal is set to 0b1).

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not part of a peripheral, but part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1_VDDS or SIM_VDDS, the corresponding PBIAS must be configured.

18.4.9.2 Extended-Drain I/O

The following MMC/SD/SDIO1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the MMC1 extended-drain I/O cell:

- sdmmc1_clk
- sdmmc1_cmd
- sdmmc1_dati (where i = 0 to 7)

The MMC1 I/O cell is powered externally through the vdds_sdmmc1 pad.

Copyright © 2011, Texas Instruments Incorporated

NOTE: The MMC1 I/O cell-associated device I/Os are also shared with other signals. gpio100gpio109, etc. are available when MuxMode is different than 0x0. If signals other than sdmmc1_x are selected , the MMC1 I/O cell must also be configured.

For more information about signal multiplexing, see Table 18-10.

For general-purpose (GP) device I/Os, which are part of the associated extended-drain cell of the GPIOWK pad , Muxmode = 3, Muxmode = 4 (gpio_wk0 pad only), and Muxmode = 6 are functional.

With Muxmode set to 0x3, the following signals are present:

- gpio_wk0
- gpio_wk1
- gpio_wk2

With Muxmode set to 0x4, the input signal (c2c_pwkup) is selected on the gpio_wk0 pad.

With Muxmode set to 0x6, the output signals (hw_dbg1, hw_dbg2, and hw_dbg3) are present at the gpio_wk0, gpio_wk1, and gpio_wk2 pads, respectively.

This PBIAS1 associated extended-drain I/O cell is externally powered through the vdds_sim pad.

NOTE: The GPIOWK-associated I/O cell must be properly configured when the gpio_wk0 through gpio_wk2 pads are used. For more information about signal multiplexing, see Table 18-10.

The following USBC1_ICUSB interface signals (selected through MuxMode = 0) use the device I/Os associated with the USBC1_ICUSB extended-drain I/O cell:

- usbc1_icusb_dp
- usbc1_icusb_dm

The USBC1_ICUSB I/O cell uses the same external power supply voltage as the GPIOWK cell (vdds_sim pad).

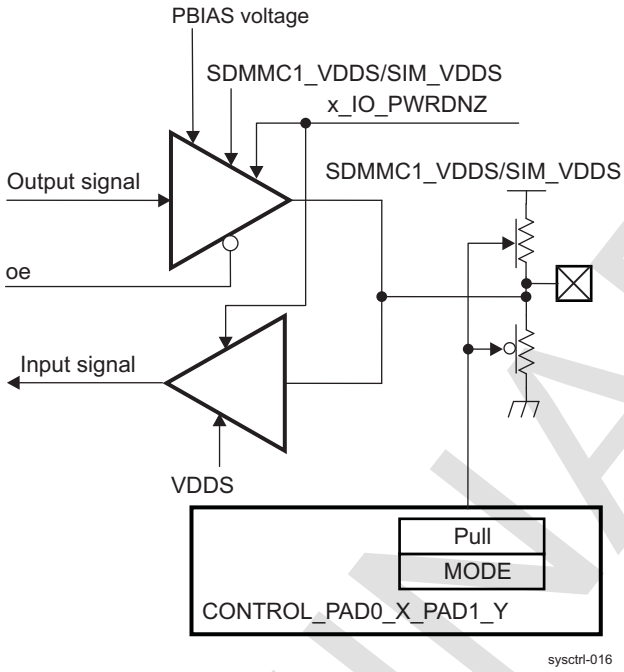
NOTE: The USBC1_ICUSB I/O cell associated device I/Os are also shared with the gpio_98 and gpio_99 signals when MuxMode = 0x3. The USBC1IC_ICUSB cell must be configured to allow for gpio_98 and gpio_99 operation. For more information about signal multiplexing, see Table 18-10.

Figure 18-13 shows the extended-drain I/O cells.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 18-13. Extended-Drain I/O



The extended-drain I/O cells have the following I/O signals:

- The output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup/down configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC1, USBC1_ICSUB, and GPIOWK I/O cells.
- The PWRDNZ signals are used to protect the I/O cells when the SDMMC1_VDDS/SIM_VDDS voltage is not stable.

CAUTION

Software must keep the PWRDNZ-related signals to 0b0 whenever the SDMMC1_VDDS or SIM_VDDS signal ramps up/down or changes. When it is set to 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- CONTROL_PBIASLITE[24] MMC1_PBIASLITE_SUPPLY_HI_OUT is a status bit on the SDMMC1_VDDS value and is used to inform the MMC1 I/O cell about the value of the SDMMC1_VDDS signal.
- CONTROL_PBIASLITE[30] PBIASLITE1_SUPPLY_HI_OUT is a status bit on the SIM_VDDS value and is used to inform the gpiowk0 through gpiowk2 associated I/O cell and USBC1_ICUSB I/O cell about the value of the SIM_VDDS signal.

For more information about the software configurations of the extended drain I/Os and PBIAS cells, see Section 18.5.1.2.2, *Extended-Drain I/Os and PBIAS Cells Programming Guide.*

Copyright © 2011, Texas Instruments Incorporated

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable VMMC1 (for the MMC/SD/SDIO1 or muxed I/O modules) or VSIM (for the GPIOWK0, GPIOWK2 , USBC1_ICUSB, or muxed I/Os) and the LDO to provide 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I^2C™) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage generated from the companion power IC and applied on the vdds_sdmmc1 or vdds_sim device pins must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground.

Table 18-14 lists the control signal with the corresponding control bits from the CONTROL_PBIASLITE, CONTROL_MMC1, and CONTROL_GPIOWK registers to configure the PBIAS and the extended-drain I/O cells. These signals can be controlled by software.

Table 18-14. PBIAS/Extended-Drain I/O Cells Control Signals

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value

PRELIMINARY

The two PBIAS cells support two ranges of I/O SDMMC1_VDDS/SIM_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See Table 18-15.

Table 18-15. Voltage Configuration[1]

PBIASLITEVMODE Configuration	SDMMC1_VDDS/SIM_VDDS Voltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration[2]
3.0 V	1.8 V	Degraded functionality[2]
3.0 V	3.0 V	Normal 3.0-V operation

(1) For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

(2) These modes must not be used.

The PBIAS output voltage is the same as SDMMC1_VDDS/SIM_VDDS voltage when the corresponding PWRDNZ bit is low. Once the SDMMC1_VDDS / SIM_VDDS supply is stable, software can release the PWRNDZ (setting it high). This starts the PBIAS cell work to generate the PBIAS voltage. During the completion process the corresponding I/Os cannot be used to transmit data. If VMODE is set correctly (compared with supply detector output and found to be the same), then PBIAS output voltage is generated based on the value of VMODE.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The VMODE bit must be defined before the PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of VMODE bit is high (indicates 3.0-V operation).
- The PWRNDZ bit must be kept low whenever the SDMMC1_VDDS/SIM_VDDS supply ramps up/down or changes. This can be damaging.
- Supply detector is disabled when PWRDNZ = 0, and in this case, supply detector output (SUPPLY_HI_OUT) is initialized to 0.

18.4.9.3 PBIAS Error Generation

If VMODE and supply detector outputs are unequal, it takes 4 µs for the comparator to process the inputs and generate the VMODE_ERROR flag.

Table 18-16 summarizes the generation of the PBIAS error signals (MMC1_PBIAS_ERROR of the MMC1_PBIAS cell, and PBIAS1_ERROR of the PBIAS1 cell), which depend on the various CONTROL_PBIASLITE bit combinations. The shaded row in the table indicates a condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDMMC1_VDDS/SIM_VDDS when the PBIAS error signal is high. This disables the I/Os.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

CAUTION

Although asserting VMODE_ERROR to 1 ensures that PBIAS voltage is equal to SDMMC1_VDDS/SIM_VDDS, this does not completely protect the I/O cells. It is recommended that all the I/Os are powered down, setting the PWRDNZ mode bits of the corresponding I/O cells to 0b0 by software as soon as VMODE_ERROR = 0b1.

Table 18-16. PBIAS Error Signal Truth Table

VMODE	PWRDNZ	HIZ_MODE	SUPPLY_HI_OUT	VMODE_ERROR
0	0	X	0	0
0	1	0	0	0
0	1	0	1	1
X	1	1	X	1
1	0	X	0	0
1	1	0	0	1
1	1	0	1	0

NOTE: VMODE_ERROR = 0b1: VMODE level is not the same as SUPPLY_HI_OUT, or HiZ mode is selected.

VMODE_ERROR = 0b0: VMODE level is the same as SUPPLY_HI_OUT, or VMODE is not considered (PWRDNZ = 0b0).

The MMC1_PBIAS_ERROR and PBIAS1_ERROR signals are ORed and the outputs are mapped to the microprocessor unit (MPU) subsystem INTC. The interrupt line MA_IRQ_75 is activated upon error occurrence. For more information about the Cortex™-A9 MPU INTC registers and their description, see the *ARM Cortex-A9 Technical Reference Manual* .

The CONTROL_PBIASLITE[29] PBIASLITE1_VMODE_ERROR and CONTROL_PBIASLITE[23] MMC1_PBIASLITE_VMODE_ERROR bits also indicate whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is critical that the PBIAS and I/O cell-related PWRDNZ bits are deasserted (made 1 from 0) only after SDMMC1_VDDS/SIM_VDDS power supply voltage is stable in the device. The cells support only the case where the 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon POR by hardware in the device. Take care to ensure that the externally provided SDMMC1_VDDS/SIM_VDDS voltage (1.8 V/ 3 V) is powered up only after VDD2 and VDDS reach their steady state.

Figure 18-14 shows the only possible power-up sequence, as well as the expected behavior of PWRNDZ mode-related bits with regard to supplying voltage ramp up.

Figure 18-14. VDDS Ramps Up Before VDD2

18.4.10 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the band gap voltage and temperature sensor (VBGAPTS) module. The band gap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature.

The main features of the VBGAPTS module are:

- A constant voltage reference output of 0.5 V
- Five constant current reference outputs of 1µA
- Analog supply is a nominal 1.8 V.
- Small ADC with 10-bit digital output
- Off mode compatible

A small finite state-machine (FSM) (band gap FSM) is instantiated inside the general core control module to help the VBGAPTS cell accomplish different measurement modes (see Section 18.4.10.2, *Temperature Sensor*) . In addition, two programmable comparator blocks inside the general core control module post-process the converted data and provide the following outputs:

- Thermal alert programmable comparator output
- Thermal shutdown programmable comparator output

Figure 18-15 shows the functional block diagram of the band gap and the temperature sensor module.

PRELIMINARY

Figure 18-15. Functional Block Diagram

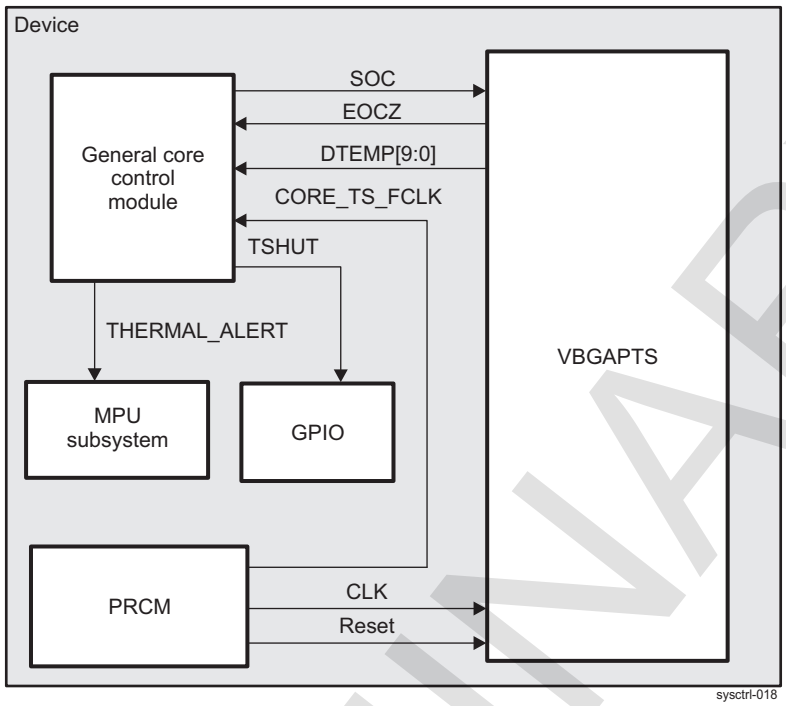

Table 18-17 describes the I/O signals, some of which (SOC, EOCZ, DTEMP[9:0]) build the interface between the VBGAPTS module and the bandgap state-machine of the general core control module.

Table 18-17. Band Gap Voltage and Temperature Sensor Signal Description

Pin	I/O (1)	Description
SOC	I	Start of Conversion signal. A transition to high starts a new ADC conversion cycle.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CLRZ	I	When low, the temperature sensor is in reset mode. This signal must be low when OFFMODE is high.
CLK	I	Functional clock in the range (1–2 MHz) from the WKUP power domain used by the temperature sensor during temperature conversion

(1) I = Input, O = Output

All the configuration signals of the VBGAPTS temperature conversion logic are available through the CONTROL_TEMP_SENSOR register.

The bandgap state-machine of the general core control module is driven by a dedicated clock (CORE_TS_FCLK) that shares a common PRCM clock source with the VBGAPTS CLK. For more information about the thermal management clocks, see Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The VBGAPTS functional clock delivered on CLK input is used only for the temperature sensor. When ADC is not converting, this clock can be switched off (CLK = 0). In this case, DTEMP[9:0] retains the temperature code obtained at the previous conversion.

NOTE: User software must ensure that the CONTROL_BANDGAP_STATUS[3] CLEAN_STOP bit read-only flag is high before switching off the VBGAPTS cell (CLK) and the bandgap state (CORE_TS_FCLK) clocks by programming the CONTROL_TEMP_SENSOR[13] BGAP_TEMPSOFF bit to 1. Status CLEAN_STOP = 1 indicates that the band gap state-machine is in IDLE state, and clocks can be safely switched off.

PRELIMINARY

Table 18-18 describes the functional outputs of the two post-processing comparator blocks integrated in the general core control module.

Table 18-18. General Core Control Thermal Logic Outputs Description

Functional Output	Description
THERMAL_ALERT	General core control module thermal alert output, mapped as an interrupt in the MPU subsystem. It is used by software to implement a thermal management policy of the device.
TSHUT	General core control module thermal shutdown comparator output, mapped on a GPIO input. This overheat protection signal is low during normal operation and goes high during a thermal shutdown event.

The configuration bits of the thermal post-processing logic are in several registers of the general core control module. For more information, see Section 18.4.10.2.3, *Thermal Data Post-Processing*.

18.4.10.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits and for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or tests.

The current reference signals consist of five lines, each of which generates a 1-µA current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 10 bits. An internal ADC, which is part of the device embedded bandgap cell, is used for conversion.

For more information about the thermal sensor operating parameters (temperature range, accuracy, etc.), see the *Temperature Sensor* section in the device data manual.

For more information about the device operating junction temperature ranges under different conditions, see the *Recommended Operating Conditions* section in the device data manual.

NOTE: The temperature measured at the temperature sensor location is lower than the temperature of the hottest spot on the device die. This difference, defined also as the temperature offset between the on-die hottest spot temperature and the temperature registered by the on-die thermal sensor, depends on a number of factors, such as the current system power dissipation, device cooling conditions, etc.

CAUTION

User software must always take care to program thermal thresholds (thermal alert or TSHUT event points) at levels that do not exceed the device hottest spot maximal-allowed temperature minus the device temperature sensor offset estimated at current conditions.

The thermal alert interrupt events are described in Section 18.4.10.2.4, *Thermal Alert Functionality Comparators*.

The TSHUT signal is connected internally to a GPIO controller pin. For more information, see Chapter 25, *General-Purpose Interface*.

The bandgap state-machine offers two operating modes for the temperature sensor: single conversion mode and repeated single conversion mode.

Copyright © 2011, Texas Instruments Incorporated

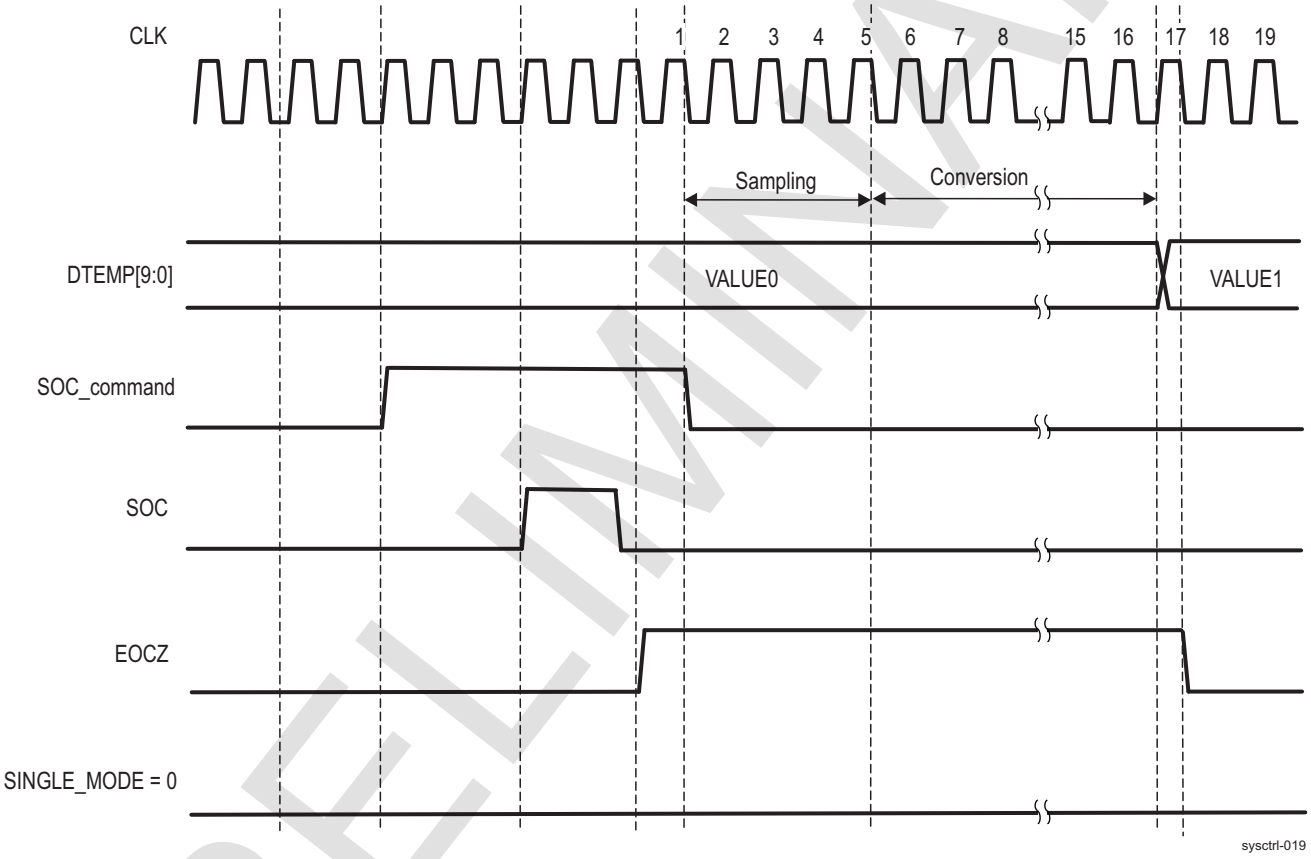
PRELIMINARY

18.4.10.2.1 Single Conversion Mode

When the ADC is idle (CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0) and the CONTROL_BANDGAP_CTRL[31] SINGLE_MODE bit is set to 0, it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion bit (CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC) must be asserted and maintained high until the end of conversion flag (CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ) goes high, after which the SOC signal must be made low by setting the CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC bit to 0. Conversion completion is indicated by a negative edge of EOCZ (the CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ bit).

Figure 18-16 shows the timing sequence of a single temperature conversion. As can be seen in the figure, a single temperature conversion is performed by ADC for 17 band gap clock cycles.

Figure 18-16. Single Conversion Mode



18.4.10.2.2 Repeated Single Conversion Mode

A continuous temperature measurement on the device is performed as a sequence of single ADC conversions automatically initiated at regular intervals. A 24-bit counter inside the general core control module adds flexibility to program the delay between two consecutive SOC pulses generated from the band gap state-machine.

Two scenarios for ADC to work in a repeated single conversion mode are:

- Fixed-delay repeated single conversions
- Programmable-delay repeated single conversions

18.4.10.2.2.1 Fixed-Delay Repeated Single Conversions

The fixed-delay repeated single conversions scenario follows the sequence:

When the ADC is idle (CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0), and

Copyright © 2011, Texas Instruments Incorporated

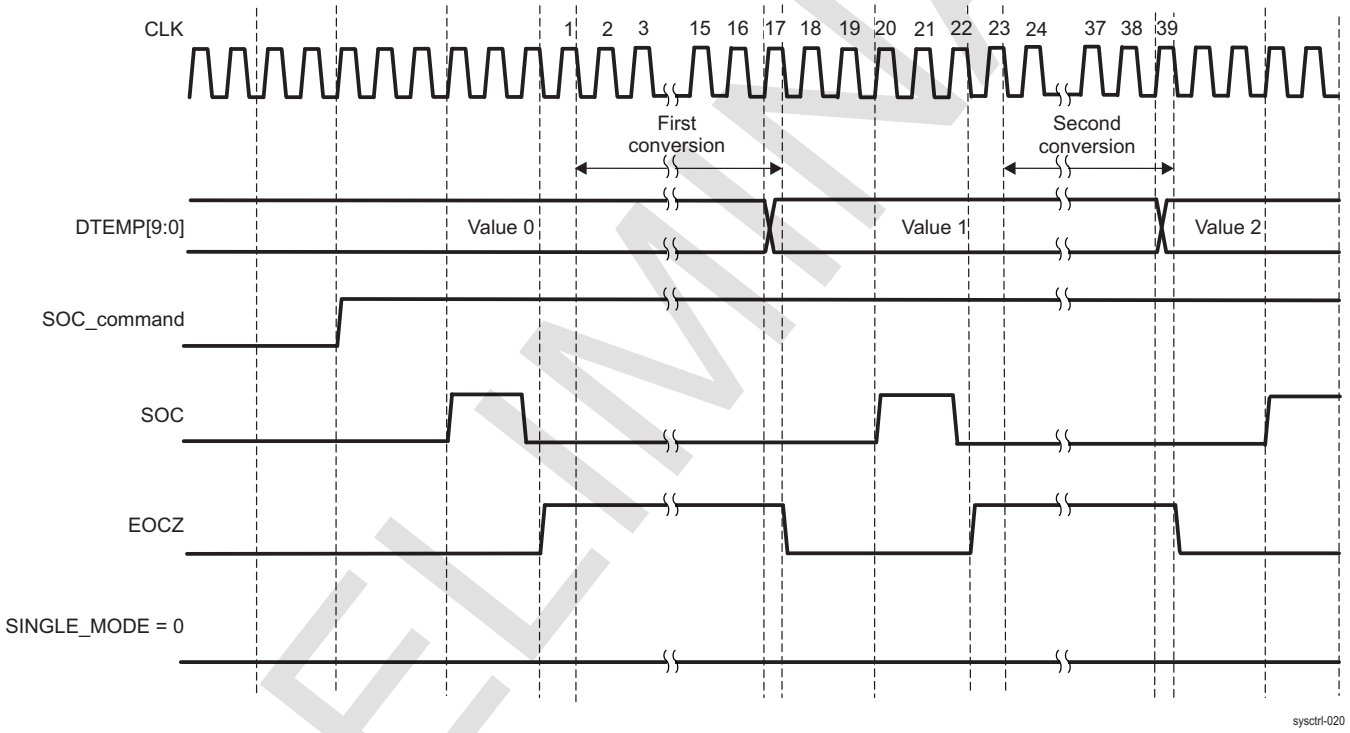
CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 0, the bandgap state-machine can be forced to generate a series of SOC pulses if the CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC bit is asserted high and continuously maintained in this state during the required temperature monitoring period. The user software must deassert the CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC bit to 0 when the CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ status bit is set high for the last temperature measurement.

As described in Section 18.4.10.2.1, *Single Conversion Mode*, valid data on the DTEMP[9:0] bus upon single conversion completion is indicated by a negative edge of the EOCZ signal. For the software, CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0 signals that the temperature data CONTROL_TEMP_SENSOR[7:0] BGAP_TEMP_SENSOR_DTEMP bit field is updated.

Figure 18-17 shows the timing sequence for fixed-delay repeated single mode.

In this case, there is no flexibility to control delay between two consecutive SOC pulses, because with CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 0 band gap counter logic is disabled .The delay is fixed to 22 bandgap functional clock cycles.

Figure 18-17. Fixed-Delay Repeated Single Conversions



18.4.10.2.2.2 Programmable-Delay Repeated Single Conversions

In the programmable-delay repeated single conversions mode the bandgap state-machine uses a 24-bit incremental counter (part of the thermal post-processing logic of the general core control module) to generate a series of SOC pulses with a programmable delay between them.

The programmable-delay repeated single conversions scenario follows this sequence:

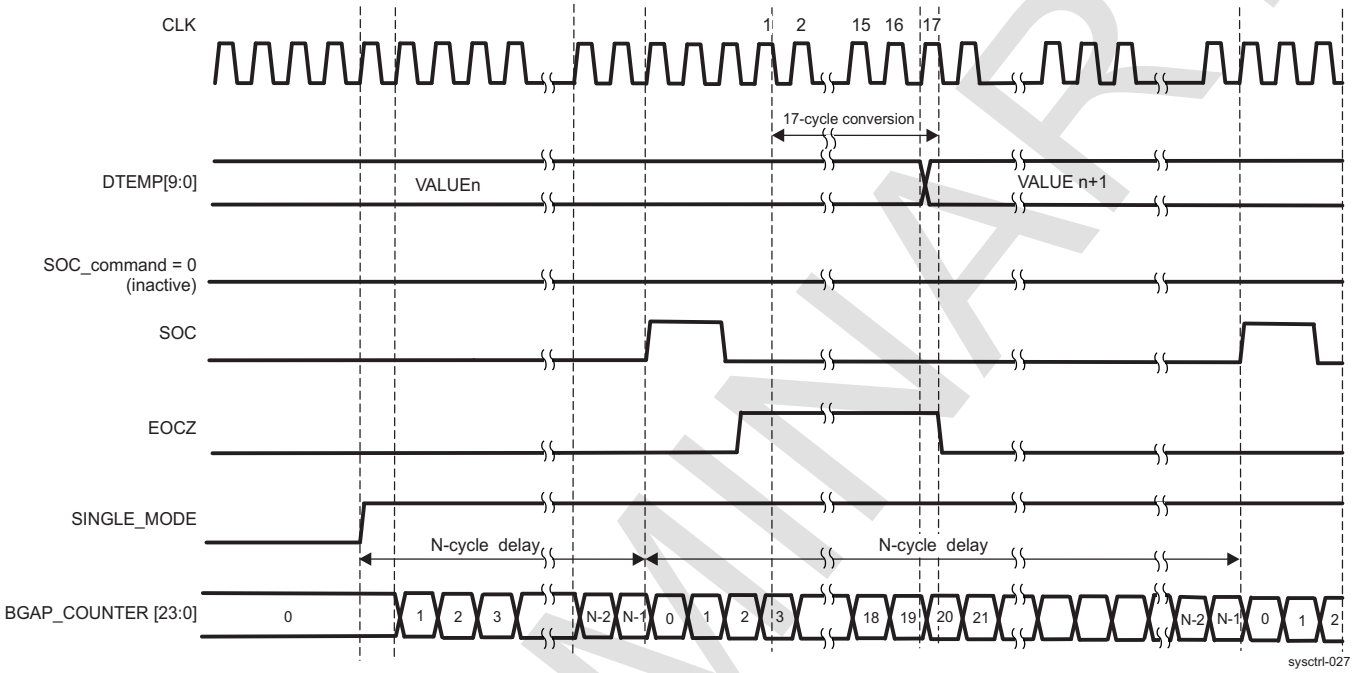
Before enabling this mode, the user must write the desired delay value as the number of bandgap CLK cycles in the CONTROL_BGAP_COUNTER[23:0] COUNTER bit field. When the ADC is idle (CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0) and CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC = 0, the user must assert CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 1 to enable programmable-delay repeated single conversions.

Copyright © 2011, Texas Instruments Incorporated

NOTE: The programmable-delay repeated single conversions require that software keeps CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC = 0 during the measurement sequence.

Figure 18-18 shows the timing sequence for a programmable-delay repeated single mode.

Figure 18-18. Programmable-Delay Repeated Single Conversions



As Figure 18-18 shows, the initial SOC pulse of a sequence is generated N-cycles after assertion of the SINGLE_MODE bit, when BGAP_COUNTER reaches N-1. The N-cycle period is repeated for consecutive SOC insertions until the sequence is stopped in software by deasserting the CONTROL_BANDGAP_CTRL[31] SINGLE_MODE bit to 0.

The signal synchronization described in Section 18.4.10.2.1, *Single Conversion Mode*, applies to each single conversion in a measurement series. The general core control module sends the SOC pulses at regular programmable intervals defined through the value of the BGAP_COUNTER bit field and registers the temperature when EOCZ is asserted low. Software must populate the correct value based on the band gap frequency and monitoring frequency, knowing that the band gap, regardless of the clock frequency, delivers its temperature after 17 clock cycles.

Table 18-19 provides examples for programming SOC pulse generation periods based on minimal (1 MHz) and maximal (2 MHz) band gap clock frequency.

Table 18-19. Bandgap Counter Programming Examples

	Monitoring Period				
Bandgap Clock	**10 ms**	**20 ms**	**50 ms**	**100 ms**	**500 ms**
1 MHz – 1000 ns	10,000 cycles	20,000 cycles	50,000 cycles	100,000 cycles	200,000 cycles
2 MHz – 500 ns	20,000 cycles	40,000 cycles	100,000 cycles	200,000 cycles	1,000,000 cycles

18.4.10.2.3 Thermal Data Post-Processing Logic

A thermal data post-processing logic with dedicated registers is implemented in the general core control module. The registered ADC value is passed in parallel to the inputs of four comparators (two sets of two comparators). In each set, the temperature data is compared to high- and low-temperature thresholds defined in software, to handle the hysteresis effect when temperature decreases. The two comparator sets provide different thermal management functions.

Figure 18-19 shows the thermal management schema in the device.

NOTE: The software settings of the comparator blocks must be applied before starting a single or repeated-single measurement sequence.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

18.4.10.2.4 Thermal Alert Functionality Comparators

The first set of comparators provides a thermal alert function output. The high- and low-temperature thresholds for this function are configurable through the 10-bit CONTROL_BANDGAP_THRESHOLD[25:16] T_HOT and CONTROL_BANDGAP_THRESHOLD[9:0] T_COLD bit fields, respectively. Thermal alert logic in the general core control module provides the capability to mask (active low) comparator outputs for hot and cold events through the CONTROL_BANDGAP_CTRL[1] MASK_HOT and CONTROL_BANDGAP_CTRL[0] MASK_COLD bits. Figure 18-20 shows the functional logic of these 2 bits to mask comparator outputs for hot and cold thermal alert events. The masked HOT and COLD point monitoring signals are then ORed in the THERMAL_ALERT signal, which delivers an interrupt to the MPU subsystem on the MA_IRQ_126 input (see Section 18.3, *Control Module Integration*). It can be used by software to implement a thermal management policy of the device. For more information about this interrupt, see Section 17.3.2,*Interrupt Requests to the Cortex-A9 MPU Interrupt Controller*.

The nonmasked outputs of the thermal alert logic comparators are individually registered in the CONTROL_BANDGAP_STATUS[1] HOT_FLAG and CONTROL_BANDGAP_STATUS[0] COLD_FLAG read-only (RO) bits. The masked ORed event (that is, the THERMAL_ALERT signal) is mapped to the CONTROL_BANDGAP_STATUS[2] BGAP_ALERT RO bit. Figure 18-20 shows the behavior of the thermal alert logic.

NOTE: The thermal processing logic of the general core control module generates an interrupt event to the MPU subsystem whenever the registered temperature of on-die thermal sensor crosses a software-configurable threshold.

CAUTION

Users must take care to program the value of the CONTROL_BANDGAP_THRESHOLD[25:16] T_HOT bit field such that its corresponding temperature value does not exceed the maximal-allowed on-die temperature minus the temperature sensor offset estimated for the current conditions. For more information about the sensed temperature value constraints, see Section 18.4.10.2, *Temperature Sensor*.

18.4.10.2.5 Thermal Shutdown Functionality Comparators

The second set of two comparators in the general core control module is responsible for the thermal shutdown protection of the device. Two 10-bit fields (CONTROL_TSHUT_THRESHOLD[25:16] TSHUT_HOT and CONTROL_TSHUT_THRESHOLD[9:0] TSHUT_COLD) define the high- and low-threshold code values, respectively. The default value of the TSHUT_HOT bit field corresponds to the maximum allowed on the device die temperature (123°C). When the maximal temperature (TSHUT_HOT) is reached, TSHUT output is activated. The TSHUT output of the general core control module is tied internally to a GPIO3 module input pin (see Section 18.3, *Control Module Integration*). Its main purpose is to indicate that the maximum junction temperature of the die is reached, which is true when the temperature measured by the on-die sensor (at sensor location), satisfies the condition:

$T_{sensor_location_max_tshut}$, °C = $T_{max_allowed_hottest_spot}$, °C – $\Delta T_{estimated_temp_offset}$, °C

To prevent device malfunction or permanent damage to the device, software must take immediate action to reduce power dissipation by warm-resetting the device or freezing most internal activities.

CAUTION

User software must always provide that the temperature corresponding to the programmed value of the CONTROL_TSHUT_THRESHOLD[25:16] TSHUT_HOT bit field does not exceed the described $T_{sensor_location_max_tshut}$ limit value. For more information about the sensed temperature value constraints, see Section 18.4.10.2, *Temperature Sensor*.

For more information about thermal-related GPIO interrupts, see Chapter 25, *General-Purpose Interface*.

To deactivate TSHUT output, the temperature ADC-encoded value must go below the value of TSHUT_COLD threshold.

CAUTION

In case of a thermal shutdown event (T_{shut_hot}, °C value exceeded), users must take care to software-trigger a warm reset on the device upon a GPIO-generated TSHUT interrupt event. The device has no hardware mechanism to automatically generate a thermal-shutdown warm reset.

Figure 18-21 shows the behavior of the TSHUT logic.

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

The general control module provides observability features covering different module internal signals related to:

- Power and reset management protocol inside different power domains
- Power domain states/transition indication
- Interrupt requests by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals are multiplexed between the general control module CORE and/or WKUP power domain and are output on the po_hw_dbg[31:0] observability bus at the boundaries of the general wake-up control module. The po_hw_dbg[31:0] observability outputs are then exported to the device control module logic to be further multiplexed as their corresponding hw_dbg[31:0] signals on the different pads of the WKUP or CORE power domain of the device control module (see Section 18.4.11.4, *Observability Signals Multiplexing at Device Control Module Level)*.

NOTE: Each signal po_hw_dbg_i (where i = 0 to 31) of the general control wakeup po_hw_dbg[31:0] bus is propagated by device control module-level logic as its corresponding hw_dbgi output signal at the device boundary (where i = 0 to 31) for the device CORE power domain pads and where i = 0 to 13 for the device WKUP power domain pads (with the constraint that hw_dbg0 and hw_dbg11 are multiplexed on the same WKUP power domain pad) described in Section 18.4.11.4, *Observability Signals Multiplexing at Device Control Module Level*.

Figure 18-22 is an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

18.4.11.2 Observability Gating Capabilities

The programmer has the option to gate all 32 signals of the observability bus simultaneously at the observability paths of the CORE and WKUP power domains , keeping them tied to 1 (CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE = 0b1) or keeping them tied to 0 (CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE = 0b1). This can be useful to check the path from hardware observability to external pads. These two bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- CORTEX-A9 MPU subsystem
-
- IVA-HD
- Display subsystem
- CM2
- ABE

When CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE = 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE and CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE simultaneously to 1 to avoid undefined states of the observability bus.

The clock frequency of the hw_dbg0, hw_dbg1, and hw_dbg2 signals can be optionally divided by 1, 2, 4, 8, or 16 through programming dedicated bit fields in CONTROL_HWOBS_CONTROL.

Assignment of dividers to the hw_dbg0, hw_dbg1, and hw_dbg2 signals applies only in the CORE power domain, as follows:

- [7:3] HWOBS_CLKDIV_SEL for hw_dbg0
- [13:9] HWOBS_CLKDIV_SEL_1 for hw_dbg1
- [18:14] HWOBS_CLKDIV_SEL_2 for hw_dbg2

NOTE: Only the CORE power domain signals hw_dbg0, hw_dbg1, and hw_dbg2 pass through the CONTROL_HWOBS_CONTROL programmable dividers. These dividers are not available to the corresponding po_hw_dbg(0), po_hw_dbg(1), and po_hw_dbg(2) lines in the WKUP power domain.

NOTE: To enable observability over the po_hw_dbg(0), po_hw_dbg(1), and po_hw_dbg(2) bus lines, the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, and HWOBS_CLKDIV_SEL_2 bit fields in the CONTROL_HWOBS_CONTROL register must be set different than 0. The default value (0) is not sufficient to see the observability value at the hw_dbg0, hw_dbg1, and hw_dbg2 pins.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

NOTE: The hw_dbg0, hw_dbg1, and hw_dbg2 frequency division and ability to gate the MACRO group observability signals (hw_dbg i, configurable in the CONTROL_HWOBS_CONTROL register) are limited to the hardware observability signals hw_dbg i (where i = 0 to 31) multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1).

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which are muxed in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0x0).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group modules/DPLLs/sDMA associated) are configurable in the General Core Control Module, which is part of the switchable CORE power domain. Signal multiplexers are also instantiated in the general wakeup control module (CM1/PRM dedicated), which is part of the WKUP power domain. The CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field, instantiated in the CORE power domain, selects a signal to be observed between the outputs at the CORE and WKUP multiplexing levels. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain po_hw_dbgn (where n = 0…31) line, and when the bit is set to 0, selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to the padconfiguration muxing I/O level within device control module boundaries.

NOTE: Although the CONTROL_DEBOBS_FINAL_MUX_SEL observability control register is in the CORE power domain, its value is retentioned before the device goes into off mode. Thus, the preserved value is used to control the final observability muxer in the WKUP power domain, even when the PD_CORE supply in the device is switched off. Because the hw_dbg i signals, which are propagated in the CORE power domain, are not available in off mode, the value of CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1 (where i = 0 to 31) in this case means that the hw_dbg i signal is not available at output.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 4-bit field MODE in the 32 × 32-bit registers CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31. The following modules can be selected as source of observability signals: Cortex-A9 MPU subsystem, IVA-HD, display subsystem , CM2, and ABE (MACRO signal sources).

Some of the CONTROL_CORE_CONF_DEBUG_SEL_TST registers are responsible for selection of sDMA view channels, different DPLL clock view channels, and other signal view channels.

- 3 x DPLL clockout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clockout view channels monitoring the hwobs_coredivider_clkout3, hwobs_perdivider_clkout4, and hwobs_pd_l4_per_per32k_gfclk signals.

Table 18-21 summarizes the internal signals multiplexing schema for each of the 32 CONTROL_CORE_CONF_DEBUG_SEL_TST registers.

A third 1:N selection layer is applied over several signals to route them one-at-a-time to a certain view channel output:

- The CONTROL_CONF_CLK_SEL0[2:0] MULT through CONTROL_CONF_CLK_SEL2[2:0] MULT bit fields control the multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of six DPLLs in the device:
  - CORE DPLL
  - ABE DPLL
  - PER DPLL
  - DSI1 DPLL
  - DSI2 DPLL
  - USB DPLL
- The register bit fields associated with the seven different DPLL signal view channels are summarized in Table 18-22. Again, the 3-bit MULT bit field in each of the seven registers makes it possible to choose the source of the DPLL signal to be one of the following device DPLLs:
  - CORE DPLL
  - ABE DPLL
  - PER DPLL
  - DSI1 DPLL

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

  - DSI2 DPLL
  - USB DPLL

- There are four independent sDMA request view channels, each of which has a dedicated register (CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3) with a 7-bit MULT bit field to select one from 127 possible sDMA request signals for observation purposes. For more information, see Chapter 16, *sDMA Controller*. The fifth channel, sdma_req_view_all, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.
- The General Core observability logic input (hwobs_pd_l4_per_per32k_gfclk) is tied to the PRM output observability signal (pd_l4_per_per_32k_gfclk). The pd_l4_per_per_32k_gfclk signal corresponds to the hardware gated in the L4_PER clock domain clock (PER_32K_FCLK), which is directly sourced by the SCRM clock (32K_FCLK). For more information, see Section 3.6.3.1, *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*. The PER_32K_FCLK and 32K_FCLK clocks are also multiplexed for observability in the WKUP domain when the PRCM.PRM_DEBUG_CFG[6:0] bit field is set to 0x6C. The observable signals are devfsm_l0.clk and gat_per_32k_gfclk_l0.clkGated, respectively. For more information, see Table 18-41, *PRM Observable Signals*.
- The General Core observability logic input, hwobs_coredivider_clkout3, is tied to the Core DPLL observability output, CLK_FUNC_1_0_3, which is a direct (nongated, nondivided) version of the CORE DPLL clock output , CLKOUTX2_M3. For more information, see Section 3.6.3.5, *DPLL_CORE Description*, in Chapter 3, *Power, Reset, and Clock Management*.
- The General Core observability logic input, hwobs_perdivider_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see Section 3.6.3.4, *DPLL_PER Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-22 lists the DPLL signal observability controls.

Table 18-22. DPLL Signal Observability Controls

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain DPLL freqlock observability	Control	CONTROL_CONF_DPLL_FREQLOCK_SEL[2:0] MULT	Selects DPLL freqlock view channel (1:8)
Different domain DPLL phaselock observability	Control	CONTROL_CONF_DPLL_PHASELOCK_SEL[2:0] MULT	Selects DPLL phaselock view channel (1:8)
Different domain DPLL tinitz observability	Control	CONTROL_CONF_DPLL_TINITZ_SEL[2:0] MULT	Selects to observe DPLL tinitzview channel (1:8)
Different domain DPLL tenable observability	Control	CONTROL_CONF_DPLL_TENABLE_SEL[2:0] MULT	Selects to observe DPLL tenableview channel (1:8)
Different domain DPLL tenablediv observability	Control	CONTROL_CONF_DPLL_TENABLEDIV_SEL[2:0] MULT	Selects to observe DPLL tenabledivview channel (1:8)
Different domain DPLL bypassack observability	Control	CONTROL_CONF_DPLL_BYPASSACK_SEL[2:0] MULT	Selects to observe DPLL bypassackview channel (1:8)
Different domain DPLL idle observability	Control	CONTROL_CONF_DPLL_IDLE_SEL[2:0] MULT	Selects to observe DPLL idleview channel (1:8)

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

NOTE: Features configured in the following registers are limited to hardware observability signals, hw_dbg i (where i = 0 to 31), multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1):

- CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31
- CONTROL_CONF_CLK_SEL0[2:0] MULT through CONTROL_CONF_CLK_SEL2[2:0] MULT
- CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3
- CONTROL_CONF_DPLL_FREQLOCK_SEL
- CONTROL_CONF_DPLL_TINITZ_SEL
- CONTROL_CONF_DPLL_PHASELOCK_SEL
- CONTROL_CONF_DPLL_TENABLE_SEL
- CONTROL_CONF_DPLL_TENABLEDIV_SEL
- CONTROL_CONF_DPLL_BYPASSACK_SEL
- CONTROL_CONF_DPLL_IDLE_SEL

These options are not applicable to hardware observability signals, hw_dbg i (where i = 0 to 31), which at the general control module level are muxed in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b0).

The CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[0] MODE bit (where i = 0…31) provides the option to choose between observation of power and reset manager signals in the device or observation of signals related to CM1. If CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[0] =0b1, the hwobs_int_prm_i signal is selected. Otherwise, the hwobs_int_cm1_i signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in Core Power Domain

To map the hw_dbg0 through hw_dbg19 signals to their associated external device pads in the CORE power domain, set the related MUXMODE bit fields within the CONTROL_CORE_PAD0_SYS_BOOT5_PAD1_DPM_EMU0 through CONTROL_CORE_PAD0_DPM_EMU19_PAD1_CSI22_DX2 padconfiguration registers to 0b110 (Mode 6). To make the remaining signals (hw_dbg20 through the hw_dbg31) available at their corresponding device pads in the CORE power domain, set the MUXMODE bit fields within the CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_USBB1_ULPITLL_CLK through CONTROL_CORE_PAD0_USBB1_ULPITLL_DAT7_PAD1_USBB1_HSIC_DATA padconfiguration registers to 0b110 (Mode 6).

For more information, see Table 18-10, *Device Core Control Module Pad Configuration Register Fields*.

For more information about hardware observability configuration, see Table 18-109, *ACTIVE PADS Configuration Points*.

NOTE: The hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the CORE power domain, are not visible when the device is set in off mode (PD_CORE supply switched off).

18.4.11.4.2 Observability Signals Muxed on Pads in WKUP Power Domain

To have hw_dbg1 through hw_dbg13 signals multiplexed on the WKUP power domain pads, set MuxMode = 0x6 in the following SYSCTRL_PADCONF_WKUP registers:

- CONTROL_WKUP_PAD0_GPIO_WK0_PAD1_GPIO_WK1 through CONTROL_WKUP_PAD0_GPIO_WK2_PAD1_GPIO_WK3[31:16] to have the hw_dbg1–hw_dbg4 signals output on the gpio_wk0–gpio_wk3 device pads, respectively
- CONTROL_WKUP_PAD0_GPIO_WK4_PAD1_SR_SCL[15:0] to have the hw_dbg5 signal output on the gpio_wk4 device pad
- CONTROL_WKUP_PAD0_FREF_CLK0_OUT_PAD1_FREF_CLK3_REQ through CONTROL_WKUP_PAD0_FREF_CLK3_OUT_PAD1_FREF_CLK4_REQ to have the hw_dbg6–hw_dbg9 signal output on the fref_clk0_out, fref_clk3_req, fref_clk3_out, and fref_clk4_req device pads, respectively
- CONTROL_WKUP_PAD0_FREF_CLK4_OUT_PAD1_SYS_32K[15:0] to have the hw_dbg10 signal output on the fref_clk4_out device pad
- CONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT[31:16] to have the hw_dbg11 signal output on the sys_pwron_reset_out device pad
- CONTROL_WKUP_PAD0_SYS_BOOT6_PAD1_SYS_BOOT7 to have the hw_dbg12 and hw_dbg13 signals output on the sys_boot6 and sys_boot7 device pads, respectively

The hw_dbg0 signal is available on the sys_pwron_reset_out pad in WKUP domain, through setting MuxMode=0x5 in theCONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT[31:16] register. Because hw_dbg11 (MuxMode=0x6) and hw_dbg0 (MuxMode=0x5) are muxed on the same pad - sys_pwron_reset_out, user should make choice between the two observable signals in WKUP domain

See Table 18-9, *Device Wakeup Control Module Pad Configuration Register Fields* for more information.

See Table 18-109, *ACTIVE PADS Configuration Points*, for more details on hardware observability configuration.

Copyright © 2011, Texas Instruments Incorporated

NOTE: If multiplexed on corresponding device pads in the WKUP power domain, the hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the WKUP power domain, can be observed even if the device goes into off mode.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (see Figure 18-22, *Overview of the Hardware Observability Functionality)*.

18.4.11.5.1 Dual Cortex-A9 Subsystem Observable Signals

Table 18-23 through Table 18-31 list the Cortex-A9 MPU subsystem observable signals available in 12 functional multiplexing modes. The mode is selected at the general core control module level by programming the CONTROL_DEBOBS_MMR_MPU[3:0] SELECT bit field. The SELECT values in range (0xC–0xF) are reserved for future use.

Table 18-23. Observability Signals Multiplexing at Cortex-A9 MPU Subsystem Level – Mode 0

The POPROFILING_EVENT2PRM bus signals, observable in modes 0, 1, 2, and 3, monitor the power states of the CPU. There are 6 status bits per Cortex-A9 CPU0 and CPU1, respectively. Table 18-27 describes the encoding of the status bits.

POPROFILING_EVENT2PRM[5:0] are the status bits for CPU0, and POPROFILING_EVENT2PRM[11:6] are the status bits for CPU1.

Table 18-27. CPU0/CPU1 PM Profiling Bus Observable Signals Description

Bit Position (CPU0)	Bit Position (CPU1)	Descriptions
5	11	**Memory in transition** 1'b0 : Memory array power transition complete 1'b1 : Memory array power transition in progress
4:3	10:9	**Memory (L1) State** 2'b00 : OFF 2'b01 : RETENTION 2'b10: Reserved 2'b11: ON
2	8	**Logic in transition** 1'b0 : Power state transition complete 1'b1 : Power state transition in progress
1:0	7:6	**Power State** 2'b00 : Power Domain is OFF. 2'b01 : Power Domain is RETENTION. 2'b10:Power Domain is ON-INACTIVE. 2'b11: Power Domain is ON-ACTIVE.

18.4.11.5.4 DSP Subsystem Observable Signals

This information is not available in the public domain.

18.4.11.5.5 ABE Subsystem Observable Signals

The audio backend (ABE) observable signals described in Table 18-38 are directly mapped to the ABE dedicated observability inputs, hwobs_int_abe[31:0] of the SYSCTRL_GENERAL_CORE module, and no additional multiplexing is performed inside the ABE.

Table 18-38. Observability Signals at ABE Subsystem Level

SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside Cortex-A9 MPU subsystem	SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside Cortex-A9 MPU Subsystem	Signal Description	Logical Value Meaning

18.4.11.5.6 USBOTGHS Subsystem Observable Signals

One of the General Wakeup Control observability inputs can be mapped to the USBOTGHS start-of-frame signal (hsusbotg_sofpulse) by setting CONTROL_CORE_CONF_DEBUG_SEL_TST_11[3:0] MODE =0x1.

18.4.11.5.7 CM2 Subsystem Observable Signals

The SYSCTRL_GENERAL_CORE observability inputs hwobs_int_cm2(i), (where i = 0…31) are mapped to the signals debugcm2(i), (where i = 0…31) coming out of the PRCM submodule, clock manager 2 (CM2).

Local multiplexing controls at the CM2 level are in the CM2_DEBUG_CFG register. The CM2 observability output signals are driven on the debugcm2(0) through debugcm2(7) lines. A certain mux set is selected by programming the CM2_DEBUG_CFG[7:0] SEL0 bit field. The remaining debugcm2(8) through debugcm2(31) lines are reserved for future use. For more information about the CM2 observability source select field, see Section 3.11.30.1, *INTRCONN_SOCKET_CM2 Register Summary*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-39 provides different details about the signals inside the CM 2 that can be monitored on device hw_dbg pins.

18.4.11.5.8 CM1 Subsystem Observable Signals

The General Wakeup Control observability inputs hwobs_int_cm1(i) , (where i = 0…31) are mapped to the signals debugcm1(i), (where i = 0…31) coming out of the PRCM submodule clock manager 1 (CM1).

Local multiplexing controls at the CM1 level are in the CM1_DEBUG_CFG register. The CM1 observability output signals are driven on the debugcm1(0) through debugcm1(7) lines. A certain mux set is selected by programming the CM1_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugcm1(8) through debugcm1(31) lines are reserved for future use. For more information about the CM1 observability source select field, see Section 3.11.22.1, *INTRCONN_SOCKET_CM1 Register Summary* in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-40provides different details about the signals inside CM1 that can be monitored on device hw_dbg pins.

Table 18-40. CM1 Observable Signals

18.4.11.5.9 PRM Subsystem Observable Signals

The General Wakeup Control observability inputs hwobs_int_prm(i), (where i = 0…31) are mapped to the signals debugprm(i),(where i = 0…31) coming out from the power reset manager (PRM) submodule.

Local multiplexing controls at the PRM level are in the PRM_DEBUG_CFG register. The PRM observability output signals are driven on the debugprm(0) through debugprm(7) lines. A certain mux set is selected by programming the PRM_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugprm(8) through debugprm(31) lines are reserved for future use. For more information about the PRM observability source select field, see Section 3.11.2.1, *INTRCONN_SOCKET_PRM Register Summary* in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-41 provides different details about the signals inside the PRM that can be monitored on device hw_dbg pins.

Table 18-41. PRM Observable Signals

18.4.11.5.10 PRCM FSM State Observable Signals Description

Some of the observable signals encode the different PRCM finite state-machine (FSM) states. Each state corresponds to a combination of FSM output signal values. The states of the different FSMs associated with the SAR RAM, DPLLs, EMIF, I/O controller, power manager, global reset manager warm reset generator, and clock managers, along with their corresponding output signal values (except for DPLL Ctrl outputs) are described in Table 18-42 through Table 18-48.

18.4.12.3 Protection Status Registers

Table 18-59 lists the status registers.

Table 18-59. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4A00 22D0	CONTROL_SEC_ERR_STATUS_FUNC	Protection firewall error status register	Public (R)
0x4A00 22D4	CONTROL_SEC_ERR_STATUS_DEBUG	Protection firewall error status register debug	Public (RW)

These registers do not depend on the device type.

The CONTROL_PROT_ERR_STATUS_FUNC can be read in public mode, but cannot be written.

The CONTROL_PROT_ERR_STATUS_DEBUG register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded-error log registers are cleared. All bits in these registers reflect internal events in the device related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clock periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode
  - CONTROL_SEC_ERR_STATUS_FUNC[01] = L3RAM protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[02] = GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[03] = EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[04] = IVA-HD protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[05] = Dual Cortex™-M3 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[06] = SL2 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[12] = C2C protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[13] = SGX protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[14] = DSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[15] = ISS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[16] = L4_PER protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[17] = L4_CFG protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[18] = DEBUGSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[19] = L4 AudioBE protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[20] = C2C INIT protection violation
- In debug mode:
  - CONTROL_SEC_ERR_STATUS_DEBUG[01] = L3RAM protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[02] = GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[03] = EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[04] = IVA-HD protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[05] = Dual Cortex-M3 protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[06] = SL2 protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[12] = C2C protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[13] = SGX protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[14] = DSS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[15] = ISS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[16] = L4_PER protection violation

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- CONTROL_SEC_ERR_STATUS_DEBUG[17] = L4_CFG protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[18] = DEBUGSS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[19] = L4 AudioBE protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[20] = C2C INIT protection violation

For more information about L4 firewall protection-violation report mechanisms , see , *Firewall Error Logging in the Control Module*. For more information about L3 firewall protection-violation report mechanisms, see , *L3 Interconnect Error Analysis.*

18.4.12.4 Protection SDRAM Configuration Registers

Table 18-60, *Protection SDRAM Configuration Registers for EMIF1 and EMIF2*, lists the protection SDRAM configuration registers for EMIF1 and EMIF2 that are part of the general wakeup control module. Upon POR, their values are exported as reset values of the EMIF1 and EMIF2 registers (EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2, respectively).

Table 18-60. Protection SDRAM Configuration Registers for EMIF1 and EMIF2

Physical Address	Register Name	Description	Access
0x4A30C110	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG register	RW
0x4A30C114	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG_2 register	RW
0x4A30C118	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG register	RW
0x4A30C11C	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG_2 register	RW

18.4.12.5 Register Controls for the LPDDR2IO1/LPDDR2IO2 I/O Buffer Modes

Global LPDDR2IO1/LPDDR2IO2 (EMIF1 and EMIF2 associated) phycmd0 and phydata0–phydata3 I/O buffer controls are part of the SYSCTRL_GENERAL_CORE.CONTROL_GEN_CORE_ OCPREG_SPARE register. Their functionality is as follows:

- Programming the OCPREG_SPARE[1] and OCPREG_SPARE[3] bits to high brings the PWRDN signal to the I/O buffers driven by the emif1/emif2phydata0 through emif/emif2phydata3 components, respectively, to low; as a consequence, power-down mode for these I/O buffers is activated.

  The PWRDN software controls do not affect the emif1/emif2phycmd0 components.
- Programming the OCPREG_SPARE[0] and OCPREG_SPARE[2] bits to high enables the low-voltage CMOS buffer logic for the emif1/emif2phydata0-emif1/emif2phydata3 and emif1/emif2phycmd0 components, respectively. Programming the OCPREG_SPARE[0] and OCPREG_SPARE[2] bits to low enables a true differential comparator.
- Upon POR, the value of the register is 0x0. The PWRDN signal is high (power-down mode is inactive) and CMOSEN is low at the pads (differential comparator enable).

CAUTION

The bits in CONTROL_GEN_CORE_OCPREG_SPARE must not be updated.

Table 18-61 lists the register used to control the described EMIF1 and EMIF2 features.

Copyright © 2011, Texas Instruments Incorporated

Table 18-61. LPDDR2IO Buffer Control Register

Physical Address	Register Name	Description	Access
0x4A0023FC	CONTROL_GEN_CORE_OCPREG_SPARE	The lower 4 bits of this register are assigned to control the power-down mode and enable the LVCMOS buffers associated with the EMIF1 and EMIF2 PHY components.	RW

18.4.12.6 EMIF DLL Master/Slave Specific Registers

18.4.12.6.1 EMIF DLL Slaves Individual Offset Compensation

Delays used to time the DQS signals of the LPDDR2 interface vary for the different DDR PHY DLL slaves associated with an EMIF controller instance. An individual offset compensation is provided for each of the four DLL slaves to achieve symmetrical timings.

Two 32-bit registers (CONTROL_EMIF1_OFFSET and CONTROL_EMIF2_OFFSET) in the general core control module are dedicated to hold four signed-offset programmable values for the EMIF1 and EMIF2 PHY DLL slaves, respectively. The following programming points apply to these registers:

- Offset is stored as 2s complement 8-bit value, ranging from –128 to +127.
- Reset value is 0 (that is, by default, no offset is applied).
- The programmed values are saved and restored during an off mode transition.

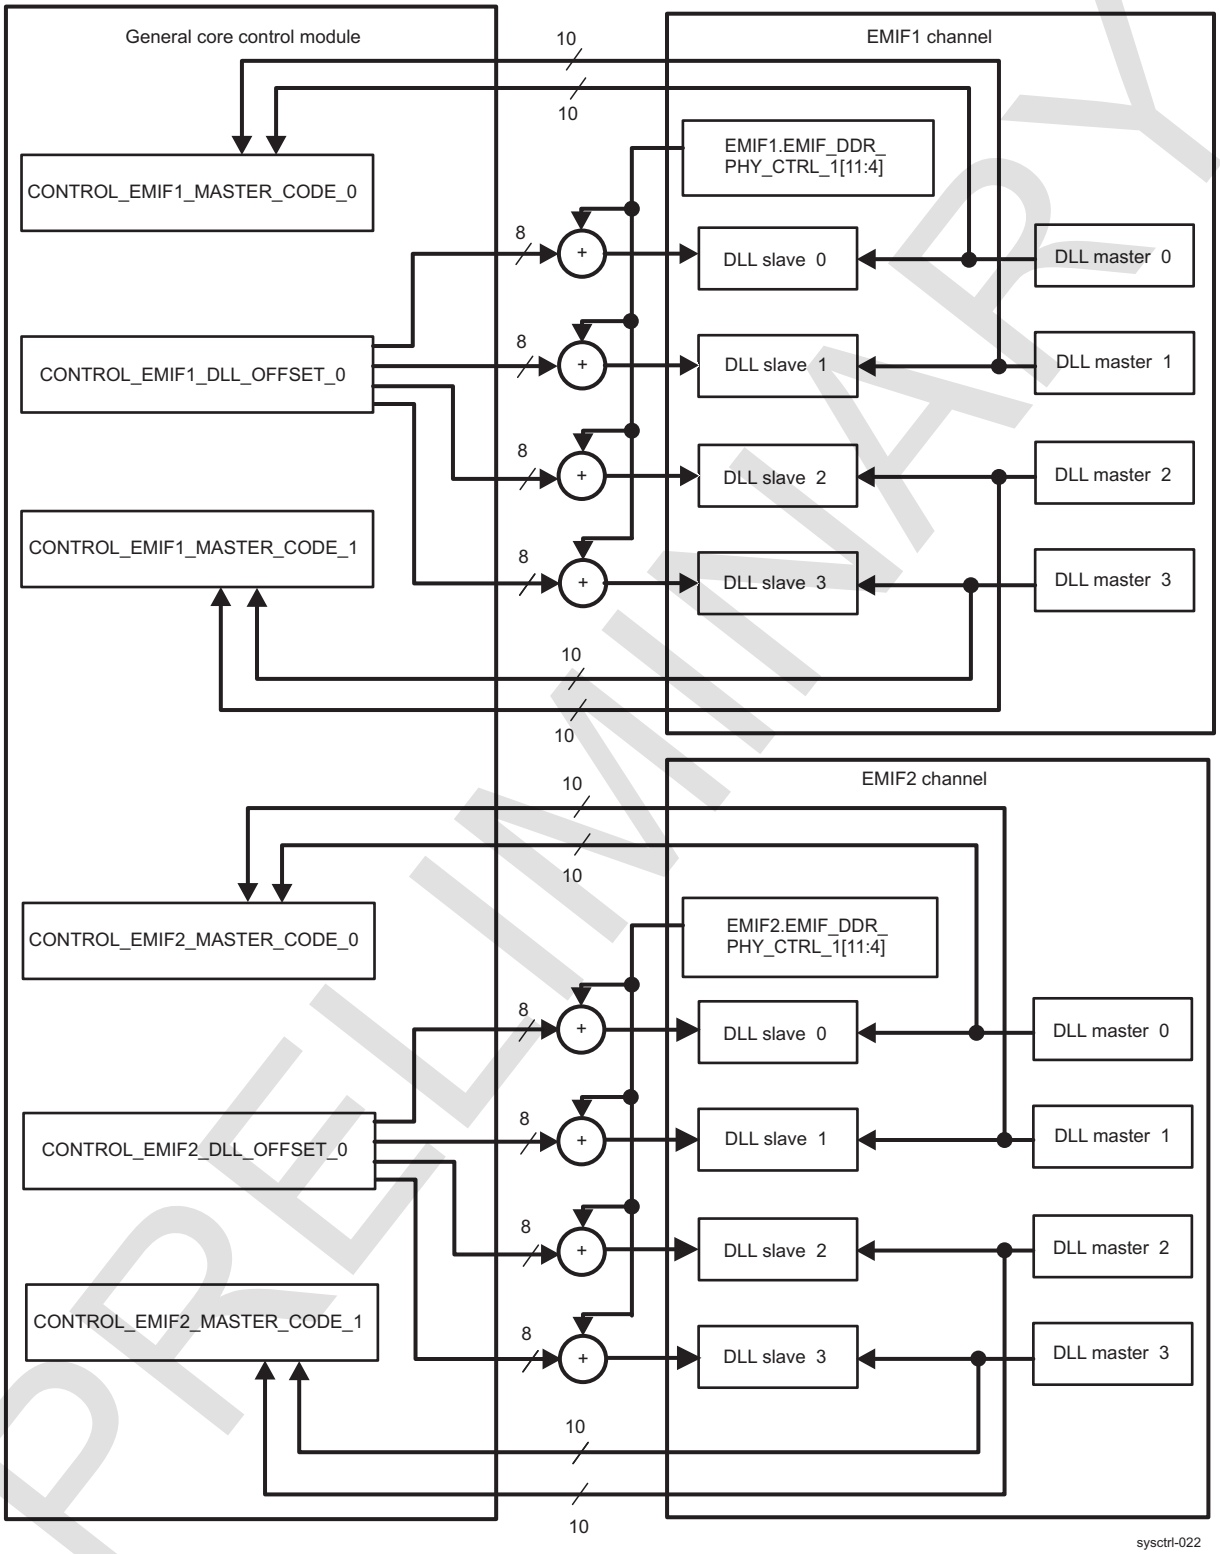
The slave delay ratio value also has a single software control for all DLLs associated with an EMIF instance (the EMIF1.EMIF_DDR_PHY_CTRL_1[11:4] REG_DLL_SLAVE_DLY_CTRL bit field in the EMIF1 address space and EMIF2.EMIF_DDR_PHY_CTRL_1[11:4] REG_DLL_SLAVE_DLY_CTRL bit field in the EMIF2 address space). For more information , see Chapter 15, *Memory Subsystem.*

The control sent to each DLL slave is the EMIF1/EMIF2 control (REG_DLL_SLAVE_DLY_CTRL) and the local signed offset, which is stored in the DLL slave corresponding bit field in the CONTROL_EMIF1_OFFSET/ CONTROL_EMIF2_OFFSET registers. DLL Slave Delay Control Schema shows the DLL slave delay control schema.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

Figure 18-23. DLL Slave Delay Control Schema



Because the adders work in saturation mode, there is no wrap-around on either end of the spectrum:

- Any value higher than 0xFF saturates to 0xFF.
- Any value lower than 0x00 saturates to 0x00.

Copyright © 2011, Texas Instruments Incorporated

Table 18-62 describes the control registers in general core control module dedicated to store delay offsets individually for the four DDR PHY DLL slaves.

Table 18-62. EMIF DLL Slave Offset Compensation Registers

Physical Address	Register Name	Description	Access
0x4A00 2360	CONTROL_EMIF1_OFFSET	EMIF1 slaves individual DLL offset controls	R/W
0x4A00 2364	CONTROL_EMIF2_OFFSET	EMIF2 slaves individual DLL offset controls	R/W

18.4.12.6.2 EMIF DLL Master Code Monitoring Registers

As can be seen in Figure 18-23, two read-only (RO) registers are provided in the general core control module to monitor DLL master codes for each of the EMIF1 and EMIF2 instances.

The 40 EMIF1 DLL master code monitoring signals are distributed as 20 read-only bits in the CONTROL_EMIF1_MASTER_CODE_0 register and 20 read-only bits in the CONTROL_EMIF1_MASTER_CODE_1 register, respectively.

Similarly, the 40 EMIF2 DLL master code monitoring signals are distributed as 20 read-only bits in the CONTROL_EMIF2_MASTER_CODE_0 register and 20 read-only bits in the CONTROL_EMIF2_MASTER_CODE_1 register, respectively.

Table 18-63 lists the control registers in general core control module dedicated to monitor the master code for the four DDR PHY DLLs.

Table 18-63. EMIF DLL Master Code-Monitoring Registers

Physical Address	Register Name	Description	Access
0x4A00 2368	CONTROL_EMIF1_MASTER_CODE_0	EMIF1 Master 0, 1 code	RO
0x4A00 236C	CONTROL_EMIF1_MASTER_CODE_1	EMIF1 Master 2, 3 code	RO
0x4A00 2370	CONTROL_EMIF2_MASTER_CODE_0	EMIF2 Master 0, 1 code	RO
0x4A00 2374	CONTROL_EMIF2_MASTER_CODE_1	EMIF2 Master 2, 3 code	RO

18.4.12.7 EMIF Read Pipeline Control Register

The EMIF1 and EMIF2 instances have dedicated control bits in the device core control module register (CONTROL_EMIF) to enable the EMIF read pipeline.

Table 18-64. EMIF Read Pipeline Control Register

Physical Address	Register Name	Description	Access
0x4A10 0694	CONTROL_EMIF	EMIF1, EMIF2 read pipeline enable	R/W

18.4.12.8 Force MPU Write Nonposted Transactions Control Register

At the top level, software can force all writes from the MPU subsystem to the L3 interconnect to be nonposted, regardless of the attributes of the transactions coming from the Cortex-A9 CPU. When active-high bit FORCEWRNP = 1, only nonposted write commands are sent to the L3 interconnect. This bit must remain stable for the entire transfer and must not change in between the transfer.

Table 18-65 describes the general core control module register with FORCEWRNP control.

PRELIMINARY

18.4.12.9 Signal Integrity Parameter Control Registers With Pad Group Assignment

18.4.12.9.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated with the device pads can be configured to deliver their carried signals to the targeted sink with maximum signal integrity. Configuration of these I/Os is done by pad group assignment and not individually per pad.

The different I/O-specific requirements determine the use of different types of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the SYSCTRL_PADCONF_CORE and SYSCTRL_PADCONF_WKUP level.

The following types of I/O cells associated with pad groups can be identified:

- LPDDR2 high-speed I/O cells with impedance(I), slew rate(SR), and weak driver (WD) settings
- High-speed I/O cells with far-end load (LB) settings
- Low -speed I/O cells with combined slew rate (SC) and load versus transmission line (TL) length (LB) settings
- Two types of I/O cells with mode (MB) controls and load compensation (LB) settings
- I/O cells with control (DS0) of the impedance mode
- C2C I/O cells with LB0 control adjustable according to interface requirement/voltage mode
- I/O cells with pullup strength (PUSTRENGTH) and speed controls
- I2Cx I/O cells with pullup resistance vers capacitance load settings
- JTAG I/O cells with bus-holder enable control

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

The pad group-assigned signal integrity controls are provided through the registers described in Table 18-66.

Table 18-66. Signal Integrity Parameter Control Registers

18.4.12.9.2 High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings

The LPDDR2IO (EMIF) buffers are based on high-speed unterminated logic and require excellent driver impedance control to achieve optimal timing–EMI trade-offs. A specific type of device I/O cell with programmable features is used to meet this requirement. These I/O cells also support the high-speed interchip (HSIC) interface.

Three types of software-configurable I/O cells are integrated to support high-speed unterminated logic:

- Single-ended I/O cells
- Two-pad differential I/O cells

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

- Vref generation cell

Two-pad differential I/O cells are provided with a differential receiver and complementary transmitter. They are used to support the LPDDR2 clock pads (lpddr21_ck, lpddr21_nck, lpddr22_ck, lpddr22_nck) and LPDDR2 strobe pads (lpddr21_dqsi, lpddr21_ndqsi, lpddr22_dqsi, and lpddr22_ndqsi ,where i = 0 to 3).

A Vref-generation cell is integrated in the device to supply a Vref-based receiver.

These I/O cells are integrated with the following controls in the SYSCTRL_PADCONF_CORE module:

- Driver output impedance (I) controls
- SR controls
- WD controls to support LPDDR2/HSIC interface and avoid floating pad
- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p1:5 and pulldown n1:5 impedance
- Internal and external reference voltage source selection for the Vref generation cell
- Vref cell decoupling capacitor selection

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program the desired impedance value of the driver.

The drive strengths corresponding to the I[2:0] value are aliased as Drv i (where i = 5 to 12) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x, (where x = 0 to 2) register tables in Section 18.6.7, *SYSCTRL_PADCONF_CORE Register Description*.

CAUTION

To ensure the best performance of the LPDDR2 I/Os, it is strongly recommended for user software to always set the impedance controlling bits (I) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x registers (where x = 0 to 2) to 0x7, which corresponds to Drv12 mode.

For more information about LPDDR2 I/O-specific driver output impedance (respectively, corresponding drive strength) parameter, see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

User software can program the slew rate (turn-on time) of the output signal using the control bits SR[1:0] in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x (where x = 0 to 2) registers.

For more information about the LPDDR2 I/O slew rate parameter control, SR[1:0], see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

Weak pullup/down or a keeper on pad is enabled through the wd0 and wd1 bits. The weak pullup/down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. Table 18-67 describes the WD controls.

NOTE: The WD[1:0] bit field controls play the role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, and provides the keeper function to the I/Os with the state WD = 0b11. For LPDDR2 I/Os, the WD controls do not apply during off mode.

Similar to the lpddr1_x and lpddr2_x pads, the usbb1_hsic_data/strobe and usbb2_hsic_data/strobe pads also have weak driver software controls for active-mode internal weak pullups and pulldowns. They are in the CONTROL_USBB_HSIC register.

Copyright © 2011, Texas Instruments Incorporated

In contrast to the LPDDR2 I/Os, the usbb1_hsic and usbb2_hsic pads are also provided with bits in the same register to select weak pullup/down and keeper function during off mode. For a given usbbx_hsic_data/strobe pad (where x = 1, 2) the associated bit to allow an off mode-specific pullup/pulldown/keeper setting is OFFMODE_WD_ENABLE. The off mode option is defined through the OFFMODE_WD[1:0] bit field in the CONTROL_USBB_HSIC register..

Table 18-67. Weak Driver PUPD/Latch Mode

WD1	WD0	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

The following sequence is required to program the off-mode pullup/pulldown /latch (keeper) feature of the usbb1_hsic_data/usbb2_hsic_data and usbb1_hsic_strobe/usbb2_hsic_strobe pads:

1. Program the desired values for USBB1_HSIC_DATA_OFFMODE_WD/ USBB2_HSIC_DATA_OFFMODE_WD and USBB1_HSIC_STROBE_OFFMODE_WD/ USBB2_HSIC_STROBE_OFFMODE_WD in the CONTROL_USBB_HSIC register.
2. For an off-mode pullup/pulldown configuration different than the active-mode pullup/pulldown configuration, set the USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_ OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_ STROBE_OFFMODE_WD_ENABLE bits to 1.

   If USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE is set to 0, the applied value of the pullup/pulldown after the device goes to off mode will be same as the value of the active pullup/pulldown (that is, in this case, the value of the OFFMODE PU/PD bit field is disregarded).

   If, for example, USBB1_HSIC_DATA_OFFMODE_WD/USBB2_HSIC_DATA_OFFMODE_WD is programmed with the same setting as USBB1_HSIC_DATA_WD/USBB2_HSIC_DATA_WD, then the value of USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ ENABLE does not matter.

   Therefore, USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_STROBE_OFFMODE_WD_ ENABLE apply only to off-mode pullup/pulldown selection.

The eFuse impedance compensation settings are exported upon POR to 10 bits in the CONTROL_EFUSE_2 register of the device control module as follows:

CONTROL_EFUSE_2[23] LPDDR2_PTV_N1 through CONTROL_EFUSE_2[19] LPDDR2_PTV_N5 (pulldown impedance trimming)

CONTROL_EFUSE_2[18] LPDDR2_PTV_P1 through CONTROL_EFUSE_2[14] LPDDR2_PTV_P5 (pullup impedance trimming)

CAUTION

Do not override the eFuse impedance compensation settings in the CONTROL_EFUSE_2 register.

NOTE: There is no software control (INPUTENABLE) for the input buffer of the high-speed unterminated logic I/Os associated with the lpddr21_x, lpddr22_x, usbb1_hsic_data/strobe, and usbb2_hsic_data/strobe pads. If the CMOS buffer is enabled, it is always bidirectional (that is, the input buffer is always enabled).

Copyright © 2011, Texas Instruments Incorporated

Internal LPDDR2IO Vref-based receivers use the output voltage of LPDDR2-associated voltage reference cells. The voltage drive selection bit fields of the LPDDR2 voltage reference cells are in the CONTROL_LPDDR2IO1_3 and CONTROL_LPDDR2IO2_3 registers. Individual VREF_TAP[1:0] control bits set the output drive capability for each of the pads (where x = 1, 2):

- lpddr2x_vref_ca_int
- lpddr2x_vref_ca
- lpddr2x_vref_dq0_int–lpddr2x_vref_dq3_int
- lpddr2x_vref_dq

Table 18-68, *LPDDR2 Internal Reference Configuration*, lists the possible options for internal reference voltage drive selection.

Table 18-68. LPDDR2 Internal Reference Configuration

VREF_TAP1	VREF_TAP0	Description
0	0	Pad/bias2 Connected to internal reference VDDS/2, for 2-µA current load
0	1	Pad/bias2 Connected to internal reference VDDS/2, for 4-µA current load
1	0	Pad/bias2 Connected to internal reference VDDS/2, for 6-µA current load
1	1	Pad/bias2 Connected to internal reference VDDS/2, for 8-µA current load

When the internal Vref generator is turned on, it supplies voltage reference to the Vref-based receivers associated with th LPDDR2IO DQ and CA interface lines.

In Vref-based receiver mode, the LPDDR2 I/O cell receiver is a true differential comparator with pad connected to the positive terminal and VREF tied to the negative terminal. The Vref-based receiver allows the improvement of speed performance at VDDS = 1.2-V I/O voltage supply.

Setting bit CONTROL_LPDDR2IOx_3[0] LPDDR2x_INT_VREF_AUTO_EN_DQ = 0b1 or CONTROL_LPDDR2IOx_3[1] LPDDR2x_INT_VREF_AUTO_EN_CA = 0b1 (where x = 1, 2) enables the automatic shut off or switch-on of the internal Vref cell generators associated with the LPDDR2x interface, the DQ and CA lines, respectively.

If user software sets the manual control bit CONTROL_LPDDR2IOx_3[2] LPDDR2x_INT_VREF_EN_DQ = 0b1 or CONTROL_LPDDR2IOx_3[3] LPDDR2x_INT_VREF_EN_CA = 0b1, internal Vref cell generators are enabled, regardless of the state of the LPDDR2x_INT_VREF_AUTO_EN_DQ/LPDDR2x_INT_VREF_AUTO_EN_CA bits. Thus, automatic control over LPDDR2 Vref cell generators can always be overridden in the context of enabling the Vref generator.

If the Vref cell generator is enabled, the following pads (where x = 1, 2) act as outputs and can be used to supply reference voltage to external devices:

- lpddr2x_vref_ca_int
- lpddr2x_vref_ca
- lpddr2x_vref_dq0_int–lpddr2x_vref_dq3_int
- lpddr2x_vref_dq (where x = 1, 2)

CAUTION

While using the Vref cell in internal reference mode, nothing else must drive the pad externally, although the pad can be connected to supply a Vref signal to other devices.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

When the internal Vref cell generators are disabled and bypassed, which is provided when the bits LPDDR2x_INT_VREF_EN_DQ/CA = 0b0 and LPDDR2x_INT_VREF_AUTO_EN_DQ/CA = 0b0, the following pads (where x = 1, 2) act as inputs that can supply voltage reference to Vref-based receivers from external sources:

- lpddr2x_vref_ca_int
- lpddr2x_vref_ca
- lpddr2x_vref_dq0_int–lpddr2x_vref_dq3_int
- lpddr2x_vref_dq

NOTE: The LPDDR2x_INT_VREF_EN_DQ and LPDDR2x_INT_VREF_AUTO_EN_DQ controls determine the direction of the lpddr2x_vref_dq0_int–lpddr2x_vref_dq3_int and lpddr2x_vref_dq pads. Similarly, the LPDDR2x_INT_VREF_EN_CA and LPDDR2x_INT_VREF_AUTO_EN_CA controls determine the direction of the lpddr2x_vref_ca_int and lpddr2x_vref_ca pads.

Table 18-69 provides different combinations of Vref cell control types, the state of the Vref cell, and the associated voltage reference pad direction.

Table 18-69. LPDDR2 Vref Cells State Description

LPDDR2x_INT_VREF_EN_DQ/CA (Manual Control Bits)	LPDDR2x_INT_VREF_AUTO_EN_DQ/CA (AUTO Control Bits)	Type of Control	Vref Cell State	Voltage Reference Pad Direction
1	x	Manual	Enabled	O
0	1	AUTO	Automatically enabled/disabled	O
0	0	–	Disabled and bypassed	I

According to the noise environment, the user can choose to filter the reference voltage, which is supplied at the internal VREF node (receiver comparators Vref input), by the Vref cell generator or by an external source. Two coupling capacitors, internal to the LPDDR2 Vref cell, are available at the internal VREF node, and are configurable as specified in Table 18-70.

Table 18-70. LPDDR2 Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDDS
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDDS as well as internal reference node and VSS

Individual VREF_CCAP0 and VREF_CCAP1 control bits in the CONTROL_LPDDR2IO1_3 and CONTROL_LPDDR2IO2_3 registers set the internal coupling capacitor connection at the internal VREF node for each of the following pads (where x = 1, 2):

- lpddr2x_vref_ca_int
- lpddr2x_vref_ca
- lpddr2x_vref_dq0_int–lpddr2x_vref_dq3_int
- lpddr2x_vref_dq

18.4.12.9.3 Low-Speed I/Os Combined Slew Rate vs TL Length and Load Settings

The low-speed I/O cells slew modes are selectable through the slew mode control SC[1:0] bit field. These settings act like coarse settings for the signal performance behavior of the low-speed I/Os.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

The low-speed I/O cells far-end capacitance load can be selected according to the transmission line (TL) length settings by modifying load bits LB[1] and LB[0] appropriately. These settings fine-tune the signal performance.

The pads featuring low-speed I/O cells require different SC[1:0] and LB[1:0] bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the different interfaces that have SC[1:0] and LB[1:0] controls and their pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific SC[1:0] and LB[1:0] bit field settings applicable to these interfaces multiplexed to low-speed I/O pads.

18.4.12.9.4 I/Os With Combined Mode and Load Settings

There are two subtypes (conditionally described as type 1 and type 2 throughout this chapter) of device I/Os, with combined mode and load settings, that differ primarily in typical output impedance and mode-specific performance. Type 1 I/Os feature a lower typical output impedance than type 2.

Both I/Os have an output buffer with an internal pad voltage SR control mechanism. Each of the type 1 and type 2 corresponding I/O cells is controlled from two mode bits (MB0 and MB1) and a dedicated bit (LB0) for load compensation. LB0 programs the CLoad for the I/O cell associated pads. The table also lists the load bit settings.

The pads featuring type 1 and type 2 I/O cells with combined mode and load settings require different MB[1:0] and LB0 bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the different interfaces that have type 1 and type 2 MB and LB0 controls and the type 1 and type 2 I/O cell pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section the device data manual provides more information about the specific MB[1:0] and LB0 bit field settings applicable to these interfaces multiplexed to type 1 and type 2 I/O pads with combined mode and load controls.

A process-only compensation using a 4-bit binary-coded schema is used separately for pullup/down output parameter variations.

For type 1 I/Os, only mode 2 does not use such compensation.

For type 2 I/Os, only mode 1 and mode 2 use eFuse process-only compensation to reduce the spread in timing parameters.

The I/Os with combined mode and load controls share the same compensation settings with the I/Os with driver output impedance (DS) settings and with the C2CI/O buffers. They are exported from eFuse upon POR to the following bits in the CONTROL_EFUSE_2 register:

CONTROL_EFUSE_2[31] EFUSE_SMART2TEST_P0 through CONTROL_EFUSE_2[28] EFUSE_SMART2TEST_P3 (pullup output parameters trimming)

CONTROL_EFUSE_2[27] EFUSE_SMART2TEST_N0 through CONTROL_EFUSE_2[24] EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

CAUTION

Do not override the SMART2TEST_P/SMART2TEST_N eFuse compensation settings in the CONTROL_EFUSE_2 register.

18.4.12.9.5 I/O Cells With Configurable Impedance Mode

The impedance mode at which this type of I/O cell operates is selected by setting a single bit drive strength control, DS0, as follows:

- DS0 = 1 selects mode 1, corresponding to 25-Ω impedance mode

Copyright © 2011, Texas Instruments Incorporated

- DS0 = 0 selects mode 2, corresponding to 50-Ω impedance mode

The pads featuring I/O cell with configurable impedance mode require different DS0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the different interfaces that have DS0 impedance mode control and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific DS0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

A process-only compensation using 4-bit binary coded schema is used separately for pullup/down output parameter variations. Only MODE1 and MODE2 use eFuse process-only compensation to reduce spread in timing parameters. The I/Os with DS0 impedance mode control share the same compensation settings with the I/Os with combined mode and load controls (both type 1 and type 2) and with the C2CI/O buffers. They are exported from eFuse upon POR to the following bits in the CONTROL_EFUSE_2 register:

CONTROL_EFUSE_2[31] EFUSE_SMART2TEST_P0 through CONTROL_EFUSE_2[28] EFUSE_SMART2TEST_P3 (pullup output parameters trimming)

CONTROL_EFUSE_2[27] EFUSE_SMART2TEST_N0 through CONTROL_EFUSE_2[24] EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

18.4.12.9.6 C2CI/O Cells With Load Setting Adjustable According to Interface Requirement Voltage Mode

To configure this type of I/O cell for different interfaces multiplexed on it, the user must manipulate in software a single bit, LB0, depending on type of multiplexed interface (C2C, GPMC, or SDMMC2) of the pad and the selected I/O voltage supply mode. Like LPDDR2IO, this I/O cell is provided with selectable LVCMOS and Vref-based receiver option. A vref pad is provided to supply reference voltage to the receiver in the 1.2-V mode. To save power at lower frequency operation, the LVCMOS receiver can be selected, and 2 bits, for each of the two C2C pad groups, are used to enable/disable the LVCMOS receiver (CMOSEN_C2C_FRM_CTRL) manually in the CONTROL_C2CIO_PADCONF_0 register.

The pads featuring C2C I/O cells with load setting adjustable according to interface requirement/voltage mode require different LB0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the different interfaces that have the interface type versus voltage mode control (LB0) and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific LB0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

NOTE: No bits are assigned to control the output drive capability of the internal C2C Vref generator (at the c2c_vref pad). It is fixed to a 2-µA current load.

If 1.2-V voltage mode is selected, the user can choose to have the LVCMOS receiver or Vref-based receiver on the C2C I/O cell pads. For the description of the dual-voltage mode settings of the C2C I/O cell pads, see Section 18.4.12.10, *Dual Voltage-Supplied Peripheral Controls*.

In Vref-based receiver mode, the C2C I/O cell receiver is a true differential comparator with pad connected to the positive terminal and VREF tied to the negative terminal. The Vref-based receiver allows the improvement of speed performance at VDDS = 1.2-V I/O voltage supply.

NOTE: The Vref-based receiver is not supported in 1.8-V mode. In this mode, the LVCMOS receiver is the only option.

Copyright © 2011, Texas Instruments Incorporated

NOTE: While at VDDS = 1.2 V, the LVCMOS receiver is supported for all C2C I/O cell pads. The Vref-based receiver is supported on only some of these pads.

The CONTROL_C2CIO_PADCONF_0[12] CMOSEN_C2C_0_FRM_CTRL and CONTROL_C2CIO_PADCONF_0[11] CMOSEN_C2C_1_FRM_CTRL bits, each related to a separate group of pads, are dedicated to select Vref-based receiver mode or LVCMOS receiver mode when VDDS = 1.2 V is selected in the CONTROL_CORE_PADCONF_MODE register.

CMOSEN_C2C_0_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver, and CMOSEN_C2C_0_FRM_CTRL = 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_ad8–gpmc_ad15
- gpmc_ncs4
- gpmc_ncs5

CMOSEN_C2C_1_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver and CMOSEN_C2C_1_FRM_CTRL= 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_a16–gpmc_a23

NOTE: The Vref-based receiver in 1.2-V mode is not supported for the following C2C I/O cell pads:

- gpmc_ad0–gpmc_ad7
- gpmc_a24
- gpmc_a25
- gpmc_ncs0–gpmc_ncs3
- gpmc_clk
- gpmc_nadv_ale
- gpmc_noe
- gpmc_nwe
- gpmc_nbe0_cle
- gpmc_nbe1
- gpmc_wait1
- gpmc_wait2
- gpmc_ncs6
- gpmc_ncs7

When the internal Vref generator is turned on, it supplies voltage reference to the Vref-based receivers supported for some C2C I/O cell pads and can also be used to drive external modules with 1.2-V reference. In this case, the c2c_vref device pad outputs voltage of the internal C2C Vref cell.

Setting bit CONTROL_C2CIO_PADCONF_0[7] C2C_INT_VREF_AUTO_EN = 0b1 enables the automatic shut off or switch-on of the internal Vref cell generator.

If user software sets the manual control bit CONTROL_C2CIO_PADCONF_0[8] C2C_INT_VREF_EN = 0b1, the internal Vref cell generator is enabled, regardless of the state of the CONTROL_C2CIO_PADCONF_0[7] C2C_INT_VREF_AUTO_EN bit. Thus, automatic control over the C2C Vref cell generator can always be overridden in the context of enabling the Vref generator.

If the Vref cell generator is enabled, the c2c_vref pad acts as output and can be used to supply reference voltage to external devices.

NOTE: At VDDS = 1.8-V voltage mode, the internal reference generator is shut off and the internal Vref cell reference node is connected to 0.

For the description of the dual-voltage mode settings of the C2C I/O cell pads, see Section 18.4.12.10, *Dual Voltage-Supplied Peripheral Controls*.

PRELIMINARY

CAUTION

While using the Vref cell in internal reference mode, nothing else must drive the pad externally, although the pad can be connected to supply the Vref signal to other devices.

When the internal Vref cell generator is disabled and bypassed, which is provided when bits CONTROL_C2CIO_PADCONF_0[8] C2C_INT_VREF_EN = 0b0 and CONTROL_C2CIO_PADCONF_0[7] C2C_INT_VREF_AUTO_EN = 0b0, the c2c_vref pad acts as input that can supply voltage reference to the Vref-based receivers from external sources.

Table 18-71 provides different combinations of Vref cell control types, the state of the Vref cell, and the associated voltage reference pad direction.

Table 18-71. C2C Vref Cell State Description

C2C_INT_VREF_EN (Manual Control Bits)	C2C_INT_VREF_AUTO_EN (AUTO Control Bits)	Type of Control	Vref Cell State	Voltage Reference Pad Direction
1	x	Manual	Enabled	O
0	1	AUTO	Automatically enabled/disabled	O
0	0	–	Disabled and bypassed	I

CAUTION

The c2c_vref pad must be externally driven only in 1.2-V voltage mode.

According to the noise environment, the user can select to filter the reference voltage, which is supplied at the internal VREF node (receiver comparators Vref input) by the Vref cell generator or by an external source. Two coupling capacitors, internal to the C2C Vref cell, are available at the internal VREF node, which is configurable as specified in Table 18-72.

Table 18-72. C2C Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDDS
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDDS as well as internal reference node and VSS

A process-only compensation using a 4-bit binary-coded schema is used separately for pullup/down output parameter variations. The C2CI/O buffers share the same compensation settings with the I/Os with combined mode and load controls (both with 25- and 50-Ω output) and I/Os with driver output impedance (DS) settings. They are exported from eFuse upon POR to the following bits in the CONTROL_EFUSE_2 register:

CONTROL_EFUSE_2[31] EFUSE_SMART2TEST_P0 through CONTROL_EFUSE_2[28] EFUSE_SMART2TEST_P3 (pullup output parameters trimming)

CONTROL_EFUSE_2[27] EFUSE_SMART2TEST_N0 through CONTROL_EFUSE_2[24] EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

PRELIMINARY

18.4.12.9.7 SDMMC1 Pullup Strength Control

The SDMMC1_PUSTRENGTH_GRPi (where i = 1 to 3) control bits are added in the CONTROL_MMC1 register to program the pullup strength for the MMC/SD/SDIO1 I/Os group.

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the different interfaces that have the pullup strength control and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific pullup strength settings applicable to these interfaces multiplexed to I/O pads with configurable pullup strength.

18.4.12.9.8 I2Cx I/Os Group Pullupresx Controls and Load Range Settings

The I2Cx buffer contains internal pullup resistors for F/S and HS modes. LB[1:0] bits are used to select an appropriate pullup resistor for a given load range.

The active high GLFENB[0] bit is implemented for I^2C receivers to enable glitch-free operation.

NOTE: The pullup versus load settings applicable to I2Cx FS mode also apply to I2Cx standard speed mode.

The type of the pullup resistor (external or internal) for a certain I2Cx I/O group (where x = 1 to 4) is selected through the I2Cx_SCL_PULLUPRESX and I2Cx_SDA_PULLUPRESX bits. Internal pullups are activated when I2Cx_SCL_PULLUPRESX / I2Cx_SDA_PULLUPRESX =0b0.

I^2C functionality is not ensured if the weak internal pullup or pulldown is activated on any of the I/Os connected to the bus.

NOTE: The user must set PULLUDENABLE = 0b0 in the I2Cx padconf registers (disable internal weak pullup resistors on i2cx pads) to ensure the full I/O cell performance capabilities of the I^2C.

The I^2C pads require different LB[1:0] and GLFENB[0] bit field settings to achieve optimal electrical performance for the multiplexed (in MuxMode = 0x0) I^2C signals. This behavior may depend on various factors:

- Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, describes the I^2C pads and their corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics/I^2C DC Electrical Characteristics* section of the device data manual provides more information about the specific LB[1:0] and GLFENB[0] bit settings applicable to I^2C I/O pads.

18.4.12.9.9 Device Interfaces Signal Group Controls Mapping

Table 18-73 through Table 18-100 describe the mapping of the signal integrity control bit fields in the different signal integrity control registers described in Table 18-66.

NOTE: The same I/O cell and I/O cell controls assigned to a pad signal available when Muxmode = 0 are shared between signals available on the same pad when Muxmode is selected different than 0. For more information, see Section 18.4.8.3, *Pad Multiplexing Register Fields*.

18.4.12.10 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1.2-V or 1.8-V power supply (VDDS through device external pads). The power supply level to the dual-voltage I/Os of different peripherals is configurable through bit fields in the CONTROL_CORE_PADCONF_MODE register in the CORE domain (EMIF, GPMC, C2C,CAMERA,and SDMMC2 I/Os) and the CONTROL_WKUP_PADCONF_MODE register in the WKUP domain (EMIF and FREF generator). One control bit in these registers is dedicated to set dual-voltage per group of pads.

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

Table 18-101 describes dual-voltage controls versus the mapping of different pads.

18.5 Control Module Programming Guide

18.5.1 Control Module Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the control module.

18.5.1.1 Global Initialization

18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the control module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. For more information, see *Section 18.2, Control Module Environment*, and Section 18.3, *Control Module Integration*.

Table 18-102. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The three clocks coming from the PRCM module (CFG_L4_ICLK , WKUP_L4_ICLK2 , and CORE_TS_FCLK) are not software-controlled by PRCM. For more information about the three clocks, see Section 3.6.3.2.4, *CM2 Clock Generator*, and Section 3.6.3.1, *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 interconnect	For information about the L4-CFG interconnect configuration, see Section 13.3, *L4 Interconnects*, in Chapter 13, *Interconnects*.

18.5.1.1.2 Control Module Global Initialization

18.5.1.1.2.1 Software Reset

The control module is not sensitive to a software reset.

18.5.1.1.2.2 Clock Gating Configuration

As described in Section 18.4.2, *Control Module Clock Configuration*, the programmer can choose a clock-gating strategy individually for each of the four control module instances. Table 18-103 explains the necessary steps.

Table 18-103. Configure Clock Gating for Different Control Module Instances

Step	Register/Bit Field/Programming Model	Value
Set clock gating for SYSCTRL_PADCONF_CORE.	CONTROL_PADCONF_CORE_SYSCONFIG[3:2]	0x-
Set clock gating for SYSCTRL_PADCONF_WKUP.	CONTROL_PADCONF_WKUP_SYSCONFIG[3:2]	0x-
Set clock gating for SYSCTRL_GENERAL_CORE.	CONTROL_GEN_CORE_SYSCONFIG[3:2] CONTROL_TEMP_SENSOR[13]	0x-
Set clock gating for SYSCTRL_GENERAL_WKUP.	CONTROL_GEN_WKUP_SYSCONFIG[3:2]	0x-

18.5.1.2 Operational Modes Configuration

18.5.1.2.1 Video Driver Configuration

This section provides information about all modules and features in the high-tier device.

For more information about the VDAC, see Section 10.6, *Video Encoder*.

PRELIMINARY

Table 18-104. Control Module AVDAC Configuration

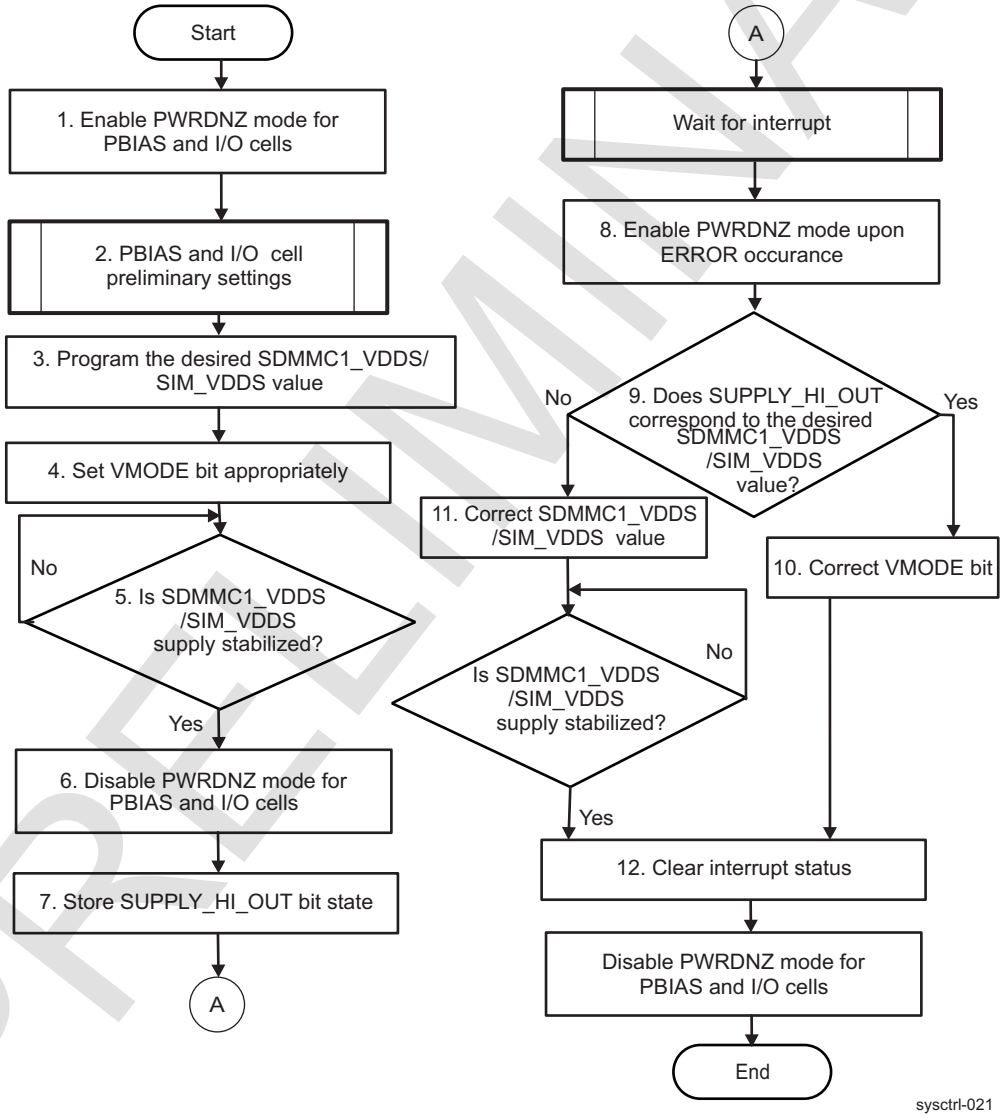
Step	Register/Bit Field/Programming Model	Value
Video buffer is bypassed or not bypassed.	CONTROL_AVDAC[30] AVDAC_TVOUTBYPASS	0b-
Enable or disable ac coupling for TV output.	CONTROL_AVDAC[31] AVDAC_ACEN	0b-

NOTE: The (VDAC) function is not supported.

18.5.1.2.2 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow from 3.0 V to 1.8 V, and vice versa, when operating with the extended-drain I/Os and PBIAS cells.

Figure 18-24. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method



PRELIMINARY

Table 18-105. Register Settings for Configuring the MMC1_PBIAS and MMC1 I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for MMC1_PBIAS cell and MMC/SD/SDIO1 I/O cell.	Software must keep MMC1_PBIAS cell and MMC1_IO cell PWRDNZ signals low whenever SDMMC1_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE[22] MMC1_PBIASLITE_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE[26] MMC1_PWRDNZ = 0b0.
2. Preliminary MMC1_PBIAS and MMC1 IO cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt. Select desired I/Os within the MMC1 I/O cell and set the corresponding pad configuration fields appropriately. Set the group speed and pullup strength controls for the MMC/SD/SDIO1 pads.	1. Set CONTROL_PBIASLITE[25]MMC1_PBIASLITE_HIZ_MODE = 0b0. 2. For information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controller*. 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, *Pad Configuration Programming Points*. 4. Set the speed control bits for the MMC1 I/O cell pads: • CONTROL_MMC1[27] SDMMC1_DR0_SPEEDCTRL = 0b- • CONTROL_MMC1[26] SDMMC1_DR1_SPEEDCTRL = 0b- • CONTROL_MMC1[28] SDMMC1_DR2_SPEEDCTRL = 0b- 5. Set the pullup strength control bits for the MMC1 I/O cell pad groups: • CONTROL_MMC1[31] SDMMC1_PUSTRENGTH_GRP0=0b- • CONTROL_MMC1[30] SDMMC1_PUSTRENGTH_GRP1=0b- • CONTROL_MMC1[29] SDMMC1_PUSTRENGTH_GRP2=0b- • CONTROL_MMC1[28] SDMMC1_PUSTRENGTH_GRP3=0b-
3. Program the desired SDMMC1_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDMMC1_VDDS voltage:(3.0 V/ 1.8 V).	For more information about I^2C interface operation, see Section 23.1, *Multimaster High-Speed I^2C*.
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SDMMC1_VDDS voltage.	Set CONTROL_PBIASLITE[21] MMC1_PBIASLITE_VMODE = 0b-(1).
5. Check whether the SDMMC1_VDDS supply is stabilized.	Check the state of the externally generated SDMMC1_VDDS voltage, which is provided through communication between the device and external power supply device over the I^2C interface.	For more information about I^2C interface settings, see Section 23.1, *Multimaster High-Speed I^2C.*
6. Disable PWRDNZ mode for MMC1_PBIAS and associated extended-drain MMC1 I/O cell.	This starts the MMC1_PBIAS cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE[22] MMC1_PBIASLITE_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE[26] MMC1_PWRDNZ = 0b1.
7. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store CONTROL_PBIASLITE[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE[26] MMC1_PWRDNZ = 0b0 . 2. Set CONTROL_PBIASLITE[22]MMC1_PBIASLITE_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SDMMC1_VDDS?	Test whether the error comes from incorrectly set value of SDMMC1_VDDS or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
10. Correct VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDMMC1_VDDS, the correct the value of the VMODE bit	Modify the value of the CONTROL_PBIASLITE[21] MMC1_PBIASLITE_VMODE bit.
11. Correct SDMMC1_VDDS value.	If SUPPLY_HI_OUT is different from expected, correct and set SDMMC1_VDDS value over I^2C again.	For more information about I^2C interface settings, see Section 23.1, *Multimaster High-Speed I^2C* ,
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controller*.

(1) Must be set high when external MMC1_VDDS source is programmed to be 3.0 V, or low when the external MMC1_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

Copyright © 2011, Texas Instruments Incorporated

Table 18-106. Register Settings for Configuring the PBIAS1 Cell, USBC1_ICUSB and gpio_wk0gpio_wk2 Associated I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for PBIAS1 cell ,USBC1_ICUSB I/O cel,l and gpiowk0–gpiowk2 associated I/O cell.	Software must keep the PBIAS1 cell and the USBC1_ICUSB and gpiowk0 - gpiowk2 I/O cells associated with the PWRDNZ signals low whenever SIM_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE[28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE[20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK[28] GPIOWK_IO_PWRDNZ = 0b0.
2. Preliminary MMC1_PBIAS and MMC1 IO cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt. Select desired I/Os within the USBC1_ICUSB and GPIOWK I/O cells and set appropriately their corresponding pad configuration fields Set the speed and pulldown controls for the pads (if applicable).	1. Set CONTROL_PBIASLITE[31] PBIASLITE1_HIZ_MODE = 0b0. 2. For more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controller*. 3. For the I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, *Pad Configuration Programming Points*. 4. Set the speed control bits for USBC1_ICUSB I/O cell pads CONTROL_MMC1[24] USBC1_DR0_SPEEDCTRL = 0b- (No speed ctrl available for GPIOWK associated I/O cell). 5. Disable strong pulldowns on the gpio_wk1 and gpio_wk2 pads available by default after reset: • CONTROL_GPIOWK[31] PAD_GPIO_WK1_LOW = 0b0 • CONTROL_GPIOWK[29] PAD_GPIO_WK2_LOW = 0b0
3. Program the desired voltage for SIM_VDDS for the USBC1_ICUSB/gpiowk0–gpiowk2 or (hw_dbg1–hw_dbg3 in WKUP domain) I/Os.	Program external power supply IC to generate appropriate SIM_VDDS voltage:(3.0 V/1.8 V)	For more information about I^2C interface operation, see Section 23.1, *Multimaster High-Speed I^2C* .
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SIM_VDDS voltage.	Set CONTROL_PBIASLITE[27] PBIASLITE1_VMODE = 0b-. (1)
5. Check whether SIM_VDDS supply is stabilized.	Check the state of the externally generated SIM_VDDS voltage.This is provided through communication between the device and the companion power supply device over the I^2C interface.	For more information about I^2C interface setting, see Section 23.1, *Multimaster High-Speed I^2C* .
6. Disable PWRDNZ mode for PBIAS1 cell and its associated extended-drain USBC1_ICUSB and gpiowk0–gpiowk2 I/O cells.	This starts the PBIAS1 cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE[28] PBIASLITE1_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE[20] USBC1_ICUSB_PWRDNZ = 0b1. 3. Set CONTROL_GPIOWK[28] GPIOWK_IO_PWRDNZ = 0b1.
7. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store the CONTROL_PBIASLITE[30] PBIASLITE1_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE[28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE[20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK[28] GPIOWK_IO_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SIM_VDDS level?	Test whether the error comes from incorrectly set value of SIM_VDDS or incorrectly set VMODE bit.	Check the stored in memory SUPPLY_HI_OUT bit.
10. Correct VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value for SIM_VDDS, the correct value of the VMODE bit.	Modify value of CONTROL_PBIASLITE[27] PBIASLITE1_VMODE.
11. Correct SIM_VDDS value.	If SUPPLY_HI_OUT is different than expected, correct and set SIM_VDDS value over I^2C again.	For more information about I^2C interface setting, see Section 23.1, *Multimaster High-Speed I^2C* .
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controller*.

(1) Must be set high when the external SIM_VDDS source is programmed to be 3.0 V, or low when the external SIM_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V .

18.5.1.2.3 Hardware Observability Settings

This section describes the procedures to control the hardware observability features of the device. To configure these features, the programmer must perform the steps listed in Table 18-107.

Table 18-107. Configure Hardware Observability Features

	Step	Register/Bit Field/Programming Model	Value
1.	Select the hwobs(0)/hwobs(1)/hwobs(2) signal frequency divider value (applies only to po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[7:3] HWOBS_CLKDIV_SEL CONTROL_HWOBS_CONTROL[13:9] HWOBS_CLKDIV_SEL_1 CONTROL_HWOBS_CONTROL[18:14] HWOBS_CLKDIV_SEL_2	0x-(1)
2.	Enable/disable gating of hwobs and alternatively set all hwobs ports to 0 or 1.	.CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE	0x-(2)
3.	Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE	0x- (3)
4.	Associate a certain hwobs channel to the CORE or WKUP power domain.	Configure each bit from the CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field appropriately for its corresponding hw_dbg channel.	0x-
5.	Choose the source of a signal or signal view channel in the CORE power domain.	Configure each CONTROL_CORE_CONF_DEBUG_SEL_TST_0[3:0] MODE through CONTROL_CORE_CONF_DEBUG_SEL_TST_31[3:0] MODE bit field appropriately for its corresponding hw_dbg channel.	0x-
6.	Choose the source of a signal within the WKUP power domain.	Configure each CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[0] MODE bit, (where i = 0 to 31) appropriately for its corresponding hw_dbg channel i (where i = 0 to 31).	0x-
7.	Choose to associate a certain DPLL signal to a given DPLL signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_DPLL_FREQLOCK_SEL[2:0] MULT .CONTROL_CONF_DPLL_TINITZ_SEL[2:0] MULT CONTROL_CONF_DPLL_PHASELOCK_SEL[2:0] MULT CONTROL_CONF_DPLL_TENABLE_SEL[2:0] MULT CONTROL_CONF_DPLL_TENABLEDIV_SEL[2:0] MULT CONTROL_CONF_DPLL_BYPASSACK_SEL[2:0] MULT CONTROL_CONF_DPLL_IDLE_SEL[2:0] MULT	0x-
8.	Choose to associate a certain clockout signal to a given clockview channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_CLK_SEL0[2:0] MULT through CONTROL_CONF_CLK_SEL2[2:0] MULT	0x-
9.	Choose to associate an sDMA signal to a given sDMA view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_SDMA_REQ_SEL0[6:0] MULT through CONTROL_CONF_SDMA_REQ_SEL3[6:0] MULT	0x-
10.	Set the appropriate pad configuration bit fields to associate the hw_dbgn pad function to output pins and configure additional output pad features.	For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *Pad Functional Multiplexing and Configuration*.	For more information, see Section 18.4.8, *PAD Functional Multiplexing and Configuration*.

(1) To configure the hwobs(0) channel to operate normally, the value of the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, or HWOBS_CLKDIV_SEL_2 bit must be set different than 0.

(2) Set both bits to 0 to enable hardware observability. Set only one bit to 1 to gate hwobs ports according to the output state required.

(3) The modules that belong to this group are: Cortex-A9 MPU subsystem, IVA-HD, display subsystem , CM2, and ABE.

For more information about the different functions and registers associated with the hardware observability features, see Section 18.4.11, *Hardware Observability*.

18.5.1.2.4 Off Mode Preliminary Settings

This section describes configurations of pads to work in off mode. The following actions must be performed once, and remain valid for all device off - on transitions.

Table 18-108. Setting Pad Off Mode Through Padconfiguration Registers

Step	Register/Bit Field/Programming Model	Value
Set OFFMODEPULLTYPESELECT bit.	CONTROL_CORE_PAD0_X_PAD1_Y[29,13] – Select pullup/down type when pad in off mode.	0b-
Set OFFMODEPULLUDENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[28,12] – Enable/disable pullup/down feature when pad in off mode.	0b-
Set OFFMODEOUTVALUE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[27,11] – Set off mode pad override value.	0b-
Set OFFMODEENABLE bit (enable/disable pad overriding capability in off mode).	CONTROL_CORE_PAD0_X_PAD1_Y[25,9] – Set pad to keep its previous state (it had before going to off mode) or force pad output to a certain override value (OFFMODEOUTVALUE) when pad in off mode.	0b-
Set OFFMODEOUTENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[26,10] – Enable/disable output in off mode.	0b-
Program a valid device ACTIVE pad configuration.	For more information about ACTIVE pad configuration, see Table 18-109.	
Set clock gating strategy.	. CONTROL_PADCONF_CORE_SYSCONFIG[3:2] IP_SYSCONFIG CONTROL_PADCONF_WKUP_SYSCONFIG[3:2] IP_SYSCONFIG	0x2,0x3
Enable/disable the wake-up detection capability(1).	CONTROL_CORE_PAD0_X_PAD1_Y[30,14]	0b-

(1) When the wake-up detection is enabled for a pad, this pad is configured as input. Therefore, be sure to write 0b1 in the OFFOUTENABLE bit to disable the output capability.

18.5.1.2.5 Pad Configuration Programming Points

This section describes through an example the configurations of pads necessary for working in active mode.

To configure the pad, ensure that the following steps are done:

1. Identify signals required on the interface based on the target application.

   Example: To configure the UART2 interface on balls, the required signals are uart2_tx, uart2_rts, uart2_cts, and uart2_rx.

2. Choose the pads used for those signals. Some signals may be available on several pads and/or may be multiplexed with other signals needed for another application. See Section 18.4.8.3, *Pad Multiplexing Register Fields.*

   Example: Unlike the UART2 interface signals, uart2_rx and uart2_tx, each of which is available on two pads, the uart2_cts and uart2_rts signals are available only on one pad each (MUXMODE = 0b000). The uart2_cts signal, however, is multiplexed with the MMC I/O signal sdmmc3_clk, and the uart2_rts signal is multiplexed with the MMC I/O signal sdmmc3_cmd on the same pad. Assume that the MMC I/O 3 interface is also required in the system. Therefore, for the MMC I/O interface signals, pads must be used where those signals are not multiplexed with a UART2 signal, if possible. In this case, the solution is to use sdmmc3_clk and sdmmc3_cmd on another two pads of the device (usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6) configuring (MUXMODE = 0b010).

3. Identify the signal integrity parameter settings (drive strength, impedance, slew rate, pullup/pulldown strength, etc.) necessary for the pads associated I/O cells, listed in Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*).

   For the register settings of the signal integrity parameters for the uart2_rx, uart2_tx, uart2_cts, and urat2_rts pads (this is the variant when the desired uart2 signals appear in MuxMode = 0x0), see Table 18-89.

Copyright © 2011, Texas Instruments Incorporated

PRELIMINARY

For the uart2_cts, uart2_rts, and uart2_rx pads, the following bit fields (Mode and Load bit group settings) must be set:

- CONTROL_SMART3IO_PADCONF_1[27:26] UART2_DR0_MB
- CONTROL_SMART3IO_PADCONF_2[13] UART2_DR0_LB

For the uart2_tx pad, the following bit fields (Mode and Load bit group settings) must be set:

- CONTROL_SMART3IO_PADCONF_1[25:24] UART2_DR1_MB
- CONTROL_SMART3IO_PADCONF_2[12] UART2_DR1_LB

For recommendations about the signal integrity parameter settings of the mentioned pad group, see the device data manual.

NOTE: To identify the signal-associated I/O cell signal parameter settings in Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, the user must search for the device pad name on which the desired signal is muxed, because the I/O cell settings are designated and listed on a per pad basis. This means that a signal name does not appear (unless MuxMode = 0x0) in Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*, but only the pad on which the signal is muxed.

Pads that do not have software I/O cell signal integrity parameter controls are not listed in Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*.

Assume the user application configures the sdmmc3_clk and sdmmc3_cmd signals on the usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6 pads (MuxMode = 0x2). The I/O cell setting (single-bit group control – SPI3_DR0_DS of driver output impedance) listed in Table 18-77 also applies to the sdmmc3_clk and sdmmc3_cmd signals, which appear on the same pads, when MuxMode = 0x2.

In this case, the CONTROL_SMART2IO_PADCONF_2[21] SPI3_DR0_DS bit must be set to configure the I/O cell performance of sdmmc3_clk and sdmmc3_clk.

For recommendations about the mentioned pad group signal integrity parameter settings, see the device data manual.

4. Identify and program the peripheral dual-voltage settings, if they apply to the chosen pads:

   Table 18-101 lists the corresponding control bits of the pads in the CONTROL_CORE_PADCONF_MODE and CONTROL_WKUP_PADCONF_MODE registers. The identification of the I/O dual voltage domains/control bits for a signal must be made on a per-pad basis.

   All pads (uart2_cts, uart2_rts, uart2_rx, and uart2_tx) fall within the same dual-voltage domain (VDDS_DV_BANK1) and the I/O supply voltage (1.2 V/1.8 V) is configured by setting the CONTROL_CORE_PADCONF_MODE[30] VDDS_DV_BANK1 bit.

   As previously explained, the sdmmc3_clk and sdmmc3_cmd signals are muxed on the usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6 pads. The dual-voltage control bit corresponding to these two pads is CONTROL_CORE_PADCONF_MODE[26] VDDS_DV_BANK6 (see Table 18-101).

   For more information about pad performance dependencies from I/O dual-voltage supply settings, see the device data manual.

5. Identify the pad configuration registers associated with the pads to be used in the application. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.

   Example: Under the previous hypothesis, the pad configuration registers to program are:

   - uart2_rts: CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[31:16]
   - uart2_cts: CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[15:0]
   - uart2_tx: CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[31:16]
   - uart2_rx: CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[15:0]
   - sdmmc3_clk (MuxMode = 0x2): CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1 _USBB2_ULPITLL_DAT7[31:16]
   - sdmmc3_cmd (MuxMode = 0x2): CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1 _USBB2_ULPITLL_DAT7[15:0]

PRELIMINARY

Table 18-109. ACTIVE PADS Configuration Points

Step	Register/Bit Field/Programming Model	Value
1. Identify the interface signals and map them to the appropriate pads according to the application requirements and the device-specific pad I/O muxing capabilities. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.	Define the list of I/O signal names: uart2_cts, uart2_rts, uart2_rx, uart2_tx, sdmmc3_clk, and sdmmc3_cmd Define the list of corresponding pads: uart2_cts, uart2_rts, uart2_rx, uart2_tx, usbb2_ulpitll_dat7, and usbb2_ulpitll_dat6	–
2. Identify the corresponding I/O cell signal integrity parameter controls for the pad (on a per-pad basis). See Section 18.4.12.9.9, *Device Interfaces Signal Group Controls Mapping*.	(uart2_cts, uart2_rts, uart2_rx pads) CONTROL_SMART3IO_PADCONF_1[27:26] UART2_DR0_MB CONTROL_SMART3IO_PADCONF_2[13] UART2_DR0_LB (uart2_tx pad) CONTROL_SMART3IO_PADCONF_1[25:24] UART2_DR1_MB CONTROL_SMART3IO_PADCONF_2[12] UART2_DR1_LB (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_SMART2IO_PADCONF_2[21] SPI3_DR0_DS	For more information about the recommended I/O settings, see the device data manual
3. Determine whether the pad is associated with a peripheral dual-voltage domain (see the device data manual). Identify its corresponding 1.2-V/1.8-V dual-voltage control bit in the CONTROL_CORE_PADCONF_MODE or CONTROL_WKUP_PADCONF_MODE register. See Table 18-101.	(uart2_cts, uart2_rts, uart2_rx, uart2_tx) CONTROL_CORE_PADCONF_MODE[30] VDDS_DV_BANK1 (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_CORE_PADCONF_MODE[26] VDDS_DV_BANK6	For more information about the I/O performance dependency on dual-voltage settings, see the device data manual.
4. Configure MUXMODE field in pad configuration registers associated with the pads used.	CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[18:16] UART2_RTS_MUXMODE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[2:0] UART2_CTS_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[18:16] UART2_TX_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[2:0] UART2_RX_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_ PAD1_USBB2_ULPITLL_DAT7[18:16] USBB2_ULPITLL_DAT7_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_ PAD1 _USBB2_ULPITLL_DAT7[2:0] USBB2_ULPITLL_DAT6_MUXMODE	0b000 0b000 0b000 0b000 0b010 0b010
5. Select the type of the internal pullup/down resistor (1).	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[4] UART2_RX_PULLTYPESELECT CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[2:0] UART2_CTS_PULLTYPESELECT	0b1 (pullup selected) 0b1 (pullup selected)
6. Enable/disable pullup/down feature of the pad (2).	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[3] UART2_RX_PULLUDENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[3] UART2_CTS_PULLUDENABLE	0b1 (pull feature enabled) 0b1 (pull feature enabled)
7. Set the direction of the pin signal.(2)	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[8] UART2_RX_INPUTENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[8] UART2_CTS_INPUTENABLE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[24] UART2_TX_INPUTENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[24] UART2_RTS_INPUTENABLE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_ PAD1_USBB2_ULPITLL_DAT7[24] USBB2_ULPITLL_DAT7_INPUTENABLE (sdmmc3_clk) CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_ PAD1 _USBB2_ULPITLL_DAT7[8] USBB2_ULPITLL_DAT6_INPUTENABLE (sdmmc3_cmd)	0b1 (input pin) 0b1 (input pin) 0b0 (output pin) 0b0 (output pin) 0b1 (input pin) 0b1 (input pin)

(1) It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.

(2) If the pad is configured in output mode, it is recommended for software to disable the internal pullup/pulldown associated with it.

PRELIMINARY

Copyright © 2011, Texas Instruments Incorporated

NOTE: The order for setting the previous pad configuration bits is not important.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding pad configuration bit CONTROL_CORE /WKUP_PAD0_X_PAD1_Y.INPUTENABLE set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

Bits	Field Name	Description	Type	Reset
13:10	EMIF1_SDRAM_CL	CAS latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices: Supported for LPDDR2-SDRAM: 0x1: CAS latency of 3 cycles 0x2: CAS latency of 4 cycles 0x3: CAS latency of 5 cycles 0x4: CAS latency of 6 cycles 0x5: CAS latency of 7 cycles 0x6: CAS latency of 8 cycles All other values are reserved.	RW	0x3
9:7	EMIF1_SDRAM_ROWSIZE	Row size. Defines the number of row address bits of connected SDRAM devices: Set to 0x0 for 9 row bits. Set to 0x1 for 10 row bits. Set to 0x2 for 11 row bits. Set to 0x3 for 12 row bits. Set to 0x4 for 13 row bits. Set to 0x5 for 14 row bits. Set to 0x6 for 15 row bits. Set to 0x7 for 16 row bits. This field is used only when the ibank_pos field in the SDRAM Config register is set to 0x1, 0x2, or 0x3.	RW	0x4
6:4	EMIF1_SDRAM_IBANK	Internal bank setup. Defines number of banks inside connected SDRAM devices: Set to 0x0 for 1 bank. Set to 0x1 for 2 banks. Set to 0x2 for 4 banks. Set to 0x3 for 8 banks. All other values are reserved.	RW	0x3
3	EMIF1_SDRAM_EBANK	External CS setup. Defines whether SDRAM accesses will use 1 or 2 CS lines. Set to 0 to use pad_cs_o_n[0] only: Set to 0x0 to use only pad_cs_o_n[0]. Set to 0x1 to use pad_cs_o_n[1:0]. This bit is automatically set to 0 if either the cs0nvmen or cs1nvmen field in the LPDDR2-NVM is set to 1.	RW	0x0
2:0	EMIF1_SDRAM_PAGESIZE	Page size. Defines the internal page size of the connected SDRAM devices: Set to 0x0 for 256-word page (8 column bits). Set to 0x1 for 512-word page (9 column bits). Set to 0x2 for 1024-word page (10 column bits). Set to 0x3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0
