12	TX3_EMPTY	MCSPI_TX3 register is empty (only when channel 3 is enabled) <sup>(2)</sup>  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
11	Reserved	Read returns 0.	RW	0x0
10	RX2_FULL	MCSPI_RX2 register full (only when channel 2 is enabled)  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
9	TX2_UNDERFLOW	MCSPI_TX2 register underflow (only when channel 2 is enabled) <sup>(1)</sup>  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
8	TX2_EMPTY	MCSPI_TX2 register empty (only when channel 2 is enabled) <sup>(2)</sup>  Write 0x0: Event status bit unchanged	RW	0x0

<sup>(1)</sup> The MCSPI\_TXx register is empty (not updated by host or DMA with new data) before its time slot assignment.  
Exception: No TX\_UNDERFLOW event when no data has been loaded into the MCSPI\_TXx register since channel has been enabled.

<sup>(2)</sup> Enabling the channel automatically rises this event.

Bits	Field Name	Description	Type	Reset
		Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.		
7	Reserved	Read returns 0.	RW	0x0
6	RX1_FULL	MCSPi_RX1 register full (only when channel 1 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
5	TX1_UNDERFLOW	MCSPi_TX1 register underflow (only when channel 1 is enabled) <sup>(1)</sup> Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
4	TX1_EMPTY	MCSPi_TX1 register empty (only when channel 1 is enabled) <sup>(2)</sup> Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
3	RX0_OVERFLOW	MCSPi_RX0 register overflow (only in slave mode) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
2	RX0_FULL	MCSPi_RX0 register full (only when channel 0 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
1	TX0_UNDERFLOW	MCSPi_TX0 register underflow (only when channel 0 is enabled) <sup>(1)</sup> Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
0	TX0_EMPTY	MCSPi_TX0 register empty (only when channel 0 is enabled) <sup>(2)</sup> Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0

**Table 19-36. MCSPI\_SYST**

<b>Address Offset</b>	0x24	<b>Instance</b>	MCSPI1
<b>Physical Address</b>	0x4809 8024		MCSPI2
	0x4809 A024		MCSPI3
	0x480B 8024		MCSPI4
	0x480B A024		MCSPI4
<b>Description</b>	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device IO pads, when the module is configured in system test (SYSTEST) mode.		
<b>Type</b>	RW		
<b>Write Latency</b>	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	PIEN_2	SPIEN_1	SPIEN_0				

Bits	Field Name	Description	Type	Reset
31:12	Reserved	Reads returns 0	RW	0x00000
11	SSB	Set status bit  0x0: No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the <a href="#">MCSPI_IRQSTATUS</a> register.	RW	0
10	SPIENDIR	Set the direction of the spim_cs lines and spim_clk line 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1] (spim_simo) 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0] (spim_somi) 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	spim_clk line (signal data value)  If <a href="#">MCSPI_SYST</a> [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_clk line (high or low) and a write into this bit has no effect.  If <a href="#">MCSPI_SYST</a> [SPIENDIR] = 0 (output mode direction), the spim_clk line is driven high or low according to the value written into this register.	RW	0
5	SPIDAT_1	spim_somi line (signal data value)  If <a href="#">MCSPI_SYST</a> [SPIDATDIR1] = 0 (output mode direction), the spim_somi line is driven high or low according to the value written into this register.	RW	0

Bits	Field Name	Description	Type	Reset
		If <b>MCSPY_SYST</b> [SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the spim_somi line (high or low) and a write into this bit has no effect.		
4	SPIDAT_0	spim_simo line (signal data value)  If <b>MCSPY_SYST</b> [SPIDATDIR0] = 0 (output mode direction), the spim_simo line is driven high or low according to the value written into this register.  If <b>MCSPY_SYST</b> [SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the spim_simo line (high or low) and a write into this bit has no effect.	RW	0
3	SPIEN_3	spim_cs3 line (signal data value)  If <b>MCSPY_SYST</b> [SPIENDIR] = 0 (output mode direction), the spim_cs3 line is driven high or low according to the value written into this register.  If <b>MCSPY_SYST</b> [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs3 line (high or low) and a write into this bit has no effect.	RW	0
2	PIEN_2	spim_cs2 line (signal data value)  If <b>MCSPY_SYST</b> [SPIENDIR] = 0 (output mode direction), the spim_cs2 line is driven high or low according to the value written into this register.  If <b>MCSPY_SYST</b> [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs2 line (high or low) and a write into this bit has no effect.	RW	0
1	SPIEN_1	spim_cs1 line (signal data value)  If <b>MCSPY_SYST</b> [SPIENDIR] = 0 (output mode direction), the spim_cs1 line is driven high or low according to the value written into this register.  If <b>MCSPY_SYST</b> [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs1 line (high or low) and a write into this bit has no effect.	RW	0
0	SPIEN_0	spim_cs0 line (signal data value)  If <b>MCSPY_SYST</b> [SPIENDIR] = 0 (output mode direction), the spim_cs0 line is driven high or low according to the value written into this register.  If <b>MCSPY_SYST</b> [SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs0 line (high or low) and a write into this bit has no effect.	RW	0

<b>Description</b>	This register is dedicated to the configuration of the channel x.		
<b>Type</b>	RW		
<b>Write Latency</b>	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Reserved	CLKG	FFER	FFEW	TCS	SBPOL	SBE	Reserved	FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM	WL					EPOL	CLKD			POL	PHA				

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Read returns 0s.	RW	0x00
29	CLKG	Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set, the <a href="#">MCSPI_CHxCTRL[15:8] EXTCLK</a> bit field must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of <a href="#">MCSPI_CHxCONF[5:2] CLKD</a> and <a href="#">EXTCLK</a> values. 0x0: Clock granularity of power of two 0x1: One clock cycle ganularity	RW	0x0
28	FFER	FIFO enabled for Receive. Only one channel can have this bit field set. 0x0: The buffer is not used to Receive data 0x1: The buffer is used to Receive data	RW	0x0
27	FFEW	FIFO enabled for Transmit. Only one channel can have this bit field set. 0x0: The buffer is not used to Transmit data 0x1: The buffer is used to Transmit data	RW	0x0
26:25	TCS	Chip select time control Defines the number of interface clock cycles between CS toggling and first (or last) edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start bit polarity 0x0: Start bit polarity is held to 0 during SPI transfer. 0x1: Start bit polarity is held to 1 during SPI transfer.	RW	0x0
23	SBE	Start bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by <a href="#">MCSPI_CHxCONF[SBPOL]</a> .	RW	0x0
22:21	Reserved	Write the reset value. Read returns the reset value.	RW	0x0
20	FORCE	Manual spim_csx assertion to keep spim_csx for channel x active between SPI words (single channel master mode only). The <a href="#">MCSPI_MODULCTRL[0] SINGLE</a> bit must bit set to 1.	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x0: Writing 0 into this bit drives the spin_csx line low for channel x when <a href="#">MCSPI_CHxCONF</a> [6] EPOL = 0, and drives it high when <a href="#">MCSPI_CHxCONF</a> [6] EPOL = 1. 0x1: Writing 1 into this bit drives the spin_csx line high for channel x when <a href="#">MCSPI_CHxCONF</a> [E6] EPOL = 0, and drives it low when <a href="#">MCSPI_CHxCONF</a> [6] EPOL = 1.		
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer) 0x1: Turbo is activated to maximize the throughput for multi-SPI word transfers.	RW	0x0
18	IS	Input select 0x0: Data Line 0 (spim_somi) selected for reception 0x1: Data Line 1 (spim_simo) selected for reception	RW	0x1
17	DPE1	Transmission enable for data line 1 (spim_simo) 0x0: Data Line 1 (spim_simo) selected for transmission 0x1: No transmission on data Line 1 (spim_simo)	RW	0x1
16	DPE0	Transmission enable for data line 0 (spim_somi) 0x0: Data Line 0 (spim_somi) selected for transmission 0x1: No transmission on data Line 0 (spim_somi)	RW	0x0
15	DMAR	DMA Read request The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA Read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0x0
14	DMAW	DMA Write request. The DMA write request line is asserted when the channel is enabled and the <a href="#">MCSPI_TXx</a> register of the channel is empty. The DMA write request line is deasserted on load completion of the <a href="#">MCSPI_TXx</a> register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0x0
13:12	TRM	Transmit/receive modes 0x0: Transmit and receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4-bit long 0x4: The SPI word is 5-bit long 0x5: The SPI word is 6-bit long 0x6: The SPI word is 7-bit long 0x7: The SPI word is 8-bit long 0x8: The SPI word is 9-bit long 0x9: The SPI word is 10-bit long 0xA: The SPI word is 11-bit long	RW	0x00

Bits	Field Name	Description	Type	Reset
		0xB: The SPI word is 12-bit long		
		0xC: The SPI word is 13-bit long		
		0xD: The SPI word is 14-bit long		
		0xE: The SPI word is 15-bit long		
		0xF: The SPI word is 16-bit long		
		0x10: The SPI word is 17-bit long		
		0x11: The SPI word is 18-bit long		
		0x12: The SPI word is 19-bit long		
		0x13: The SPI word is 20-bit long		
		0x14: The SPI word is 21-bit long		
		0x15: The SPI word is 22-bit long		
		0x16: The SPI word is 23-bit long		
		0x17: The SPI word is 24-bit long		
		0x18: The SPI word is 25-bit long		
		0x19: The SPI word is 26-bit long		
		0x1A: The SPI word is 27-bit long		
		0x1B: The SPI word is 28-bit long		
		0x1C: The SPI word is 29-bit long		
		0x1D: The SPI word is 30-bit long		
		0x1E: The SPI word is 31-bit long		
		0x1F: The SPI word is 32-bit long		
6	EPOL	spim_csx polarity for channel x 0x0: spim_csx is held high during the active state. 0x1: spim_csx is held low during the active state.	RW	0x0
5:2	CLKD	Frequency divider for spim_clk (for master device only) A programmable clock divider divides the SPI reference clock (CLKSPIREF) by a 4-bit value and results in a new spim_clk clock available to shift data in and out. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: Division not supported 0xE: Division not supported 0xF: Division not supported	RW	0x0
1	POL	spim_clk polarity 0x0: spim_clk is held high during the active state. 0x1: spim_clk is held low during the active state.	RW	0x0
0	PHA	spim_clk phase 0x0: Data are latched on odd-numbered edges of spim_clk. 0x1: Data are latched on even-numbered edges of spim_clk.	RW	0x0

## **HDQ/1-Wire**

---

---

---

This chapter describes the features and functions of the HDQ/1-Wire module for the OMAP34xx multimedia device.

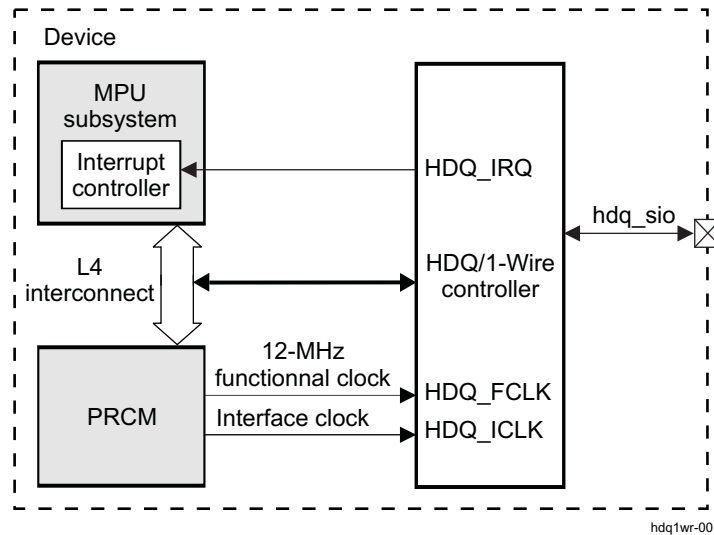

<b>Topic</b>	<b>Page</b>
<b>20.1 HDQ/1-Wire Overview .....</b>	<b>2845</b>
<b>20.2 HDQ/1-Wire Environment .....</b>	<b>2847</b>
<b>20.3 HDQ/1-Wire Integration .....</b>	<b>2850</b>
<b>20.4 HDQ/1-Wire Functional Description .....</b>	<b>2852</b>
<b>20.5 HDQ/1-Wire Basic Programming Model .....</b>	<b>2858</b>
<b>20.6 HDQ/1-Wire Use Cases and Tips .....</b>	<b>2861</b>
<b>20.7 HDQ/1-Wire Register Manual .....</b>	<b>2865</b>

## 20.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slave (HDQ/1-Wire external compliant device).

Figure 20-1 shows the HDQ/1-Wire controller module.

**Figure 20-1. HDQ/1-Wire Highlight**

The HDQ and 1-Wire module has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The HDQ operates from a fixed 12-MHz functional clock provided by the PRCM module.

Only the MPU subsystem uses the HDQ/1-Wire module.

The main features of the HDQ/1-Wire module support the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire module provides a communication rate of 5K bits/s over an address space of 128 bytes.

A typical application of the HDQ/1-Wire module is the communication with battery monitor (gas gauge) integrated circuits.

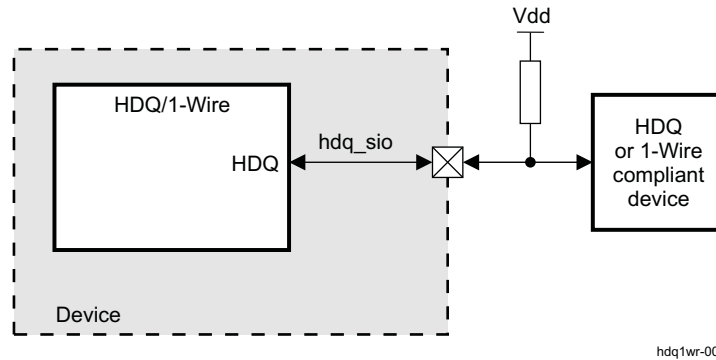

## 20.2 HDQ/1-Wire Environment

### 20.2.1 HDQ/1-Wire Functional Interface

Figure 20-2 shows a typical application using the HDQ/1-Wire connection.

Figure 20-2. HDQ/1-Wire Typical Application System Overview

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command, the line is pulled to a logical high level).

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in [Section 20.5](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 20-1](#) describes the external pullup signal from an HDQ or 1-Wire compliant device.

Table 20-1. I/O Description

Signal Name	I/O	Description	Value at Reset
hdq_sio	Bidir	Serial data input/output	1

### 20.2.2 HDQ and 1-Wire (SDQ) Protocols

#### 20.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ.HDQ\_CTRL\_STATUS[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.HDQ\_TX\_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time  $t(B)$  or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time  $t(BR)$ . The slave is then ready for a command from the host processor. Figure 20-3 shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

**Figure 20-3. HDQ Break-Pulse Timing Diagram**

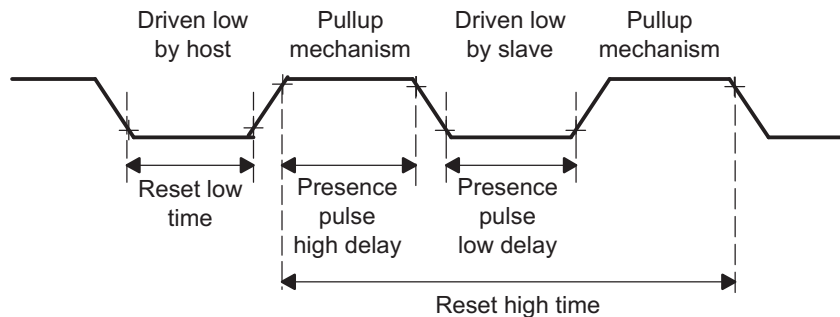

### 20.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in Figure 20-4 shows the 1-Wire (SDQ) reset sequence.

**Figure 20-4. 1-Wire (SDQ) Reset Timing Diagram**

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

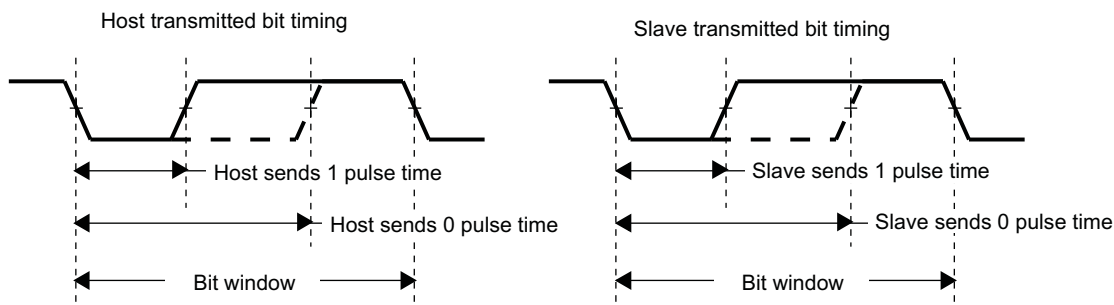

On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

### 20.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 20-5.

Figure 20-5. HDQ/1-Wire Transmitted Bit Timing

hdq1wr-005

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

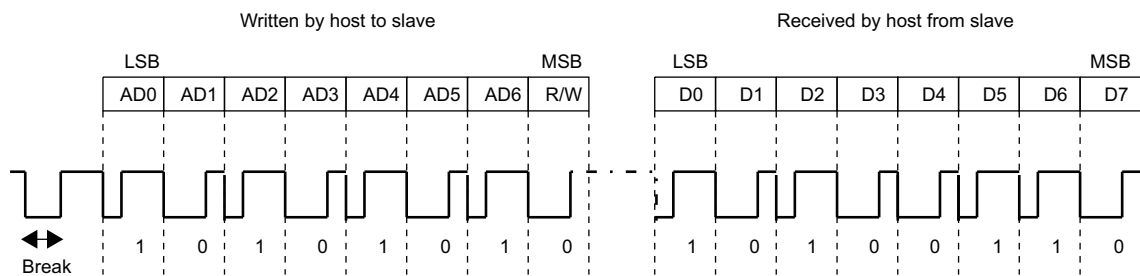

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 20-2 lists the command byte values.

Table 20-2. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

- R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.
- AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in Figure 20-6 shows a read command at address 0x55; the received data is 0x65.

## 20.3 HDQ/1-Wire Integration

Figure 20-7 shows the HDQ/1-Wire module integration in the device.

**Figure 20-7. HDQ/1-Wire Integration**

hdq1wr-007

### 20.3.1 Clocking, Reset, and Power Management Scheme

#### 20.3.1.1 HDQ/1-Wire Clocks

There are two clock domains in the HDQ/1-Wire module: the functional clock domain and the interface clock domain.

- HDQ\_FCLK belongs to the functional clock domain. It is a fixed 12-MHz clock provided by the PRCM. It is used to clock the internal module logic.

The HDQ\_FCLK source is the CORE\_12M\_FCLK PRCM output, which is derived from the CORE\_48M\_FCLK clock signal (a 1/4 ratio is applied). The CORE\_12M\_FCLK clock is issued from the peripherals DPLL4. For more information about the clock, see [Chapter 4, Power, Reset, and Clock Management](#).

When the HDQ/1-Wire module no longer requires the HDQ\_FCLK, the software can disable it at the PRCM level by setting the EN\_HDQ bit (PRCM.CM\_FCLKEN1\_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and DPLL4 configuration, see [Chapter 4, Power, Reset, and Clock Management](#).

- HDQ\_ICLK is the interface clock. It runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface. Its source is the PRCM CORE\_L4\_ICLK signal. It typically runs at L3/2 frequency.

When the HDQ/1-Wire module no longer requires the HDQ\_ICLK, the software can disable it at the PRCM level by setting the EN\_HDQ bit (PRCM.CM\_ICLKEN1\_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

It is also possible to activate an autoidle mode for this clock (AUTO\_HDQ bit PRCM.CM\_AUTOIDLE1\_CORE[22] set to 1). In this case, HDQ\_ICLK follows the CORE clock domain behavior. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

#### 20.3.1.2 HDQ/1-Wire Reset Scheme

Global reset of the module is done either by activating the CORE\_RST signal in the CORE\_RST domain (for more information, see [Chapter 4, Power, Reset, and Clock Management](#)) or by setting to 1 the SOFTRESET bit HDQ.HDQ\_SYSCONFIG[1]. Setting this bit enables an active software reset functionality equivalent to a hardware reset.

### 20.3.1.3 HDQ/1-Wire Power Domain

The HDQ/1-Wire belongs to the CORE power domain. For more information about the CORE power domain, see [Chapter 4, Power, Reset, and Clock Management](#).

### 20.3.2 Hardware Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ\_IRQ: This is an interrupt to the MPU subsystem interrupt controller. It is mapped on M\_IRQ\_58.

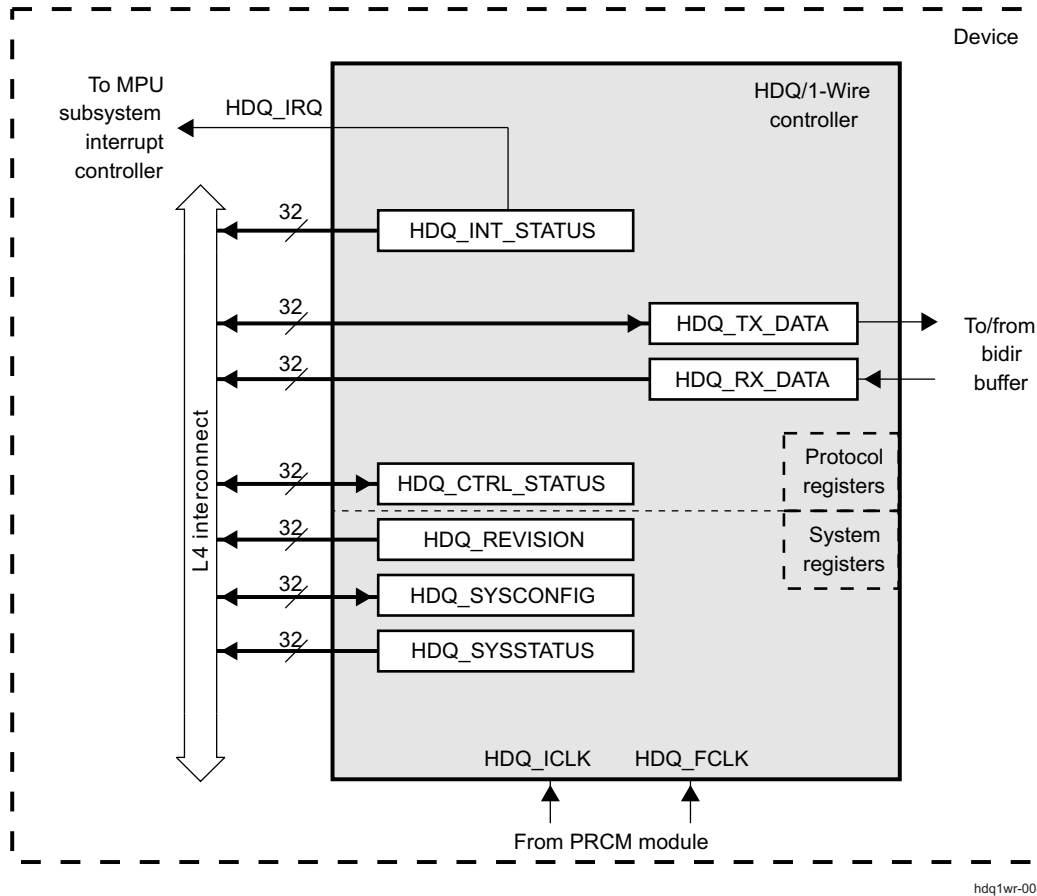

## 20.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

### 20.4.1 HDQ/1-Wire Block Diagram

Figure 20-8 shows the HDQ/1-Wire block diagram.

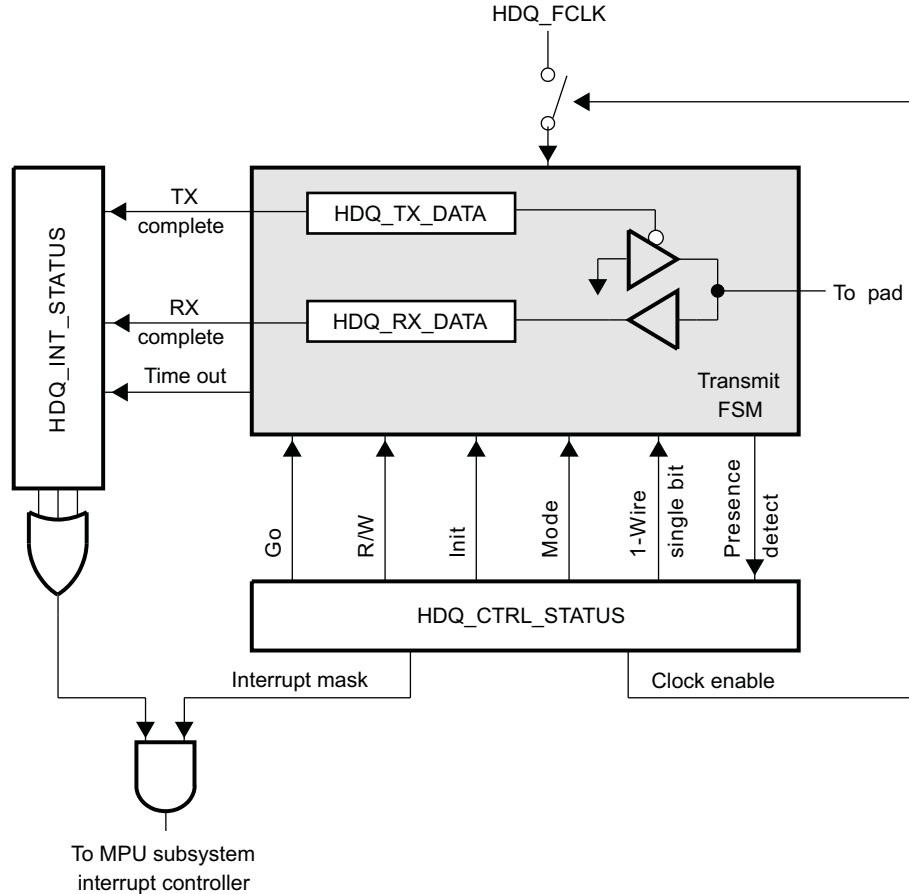

Figure 20-8. HDQ/1-Wire Block Diagram

The MODE bit `HDQ.HDQ_CTRL_STATUS[0]` allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 20-9 shows the protocol-dedicated register scheme.

Figure 20-9. Protocol Registers Description

hdq1wr-009

The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the OMAP device and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

## 20.4.2 HDQ Mode (Default)

### 20.4.2.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

### 20.4.2.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the INITIALIZATION bit HDQ.HDQ\_CTRL\_STATUS[2] creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ.HDQ\_INT\_STATUS[0] is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.HDQ\_INT\_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.HDQ\_INT\_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

#### 20.4.2.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1\_WIRE\_SINGLE\_BIT bit HDQ.HDQ\_CTRL\_STATUS[7] set to 1) has no effect because the HDQ protocol supports only byte transfers.

#### 20.4.2.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).

2. Read complete:

In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).

3. Presence detect/time-out:

In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).

In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

### 20.4.3 1-Wire Mode

#### 20.4.3.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

#### 20.4.3.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after INITIALIZATION bit HDQ.HDQ\_CTRL\_STATUS[2] is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the PRESENCEDETECT bit HDQ.HDQ\_CTRL\_STATUS[3].

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the TIMEOUT bit HDQ.HDQ\_INT\_STATUS[0] is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ\_INT\_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register (HDQ.HDQ\_RX\_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

#### 20.4.3.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (1\_WIRE\_SINGLE\_BIT bit HDQ.HDQ\_CTRL\_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register (HDQ.HDQ\_RX\_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ\_TX\_DATA) contains the bit to be sent.

#### 20.4.3.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:  
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
2. Read complete:  
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
3. Presence detect/time-out:  
In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

#### 20.4.3.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ.HDQ\_CTRL\_STATUS[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ.HDQ\_INT\_STATUS[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

### 20.4.4 Module Power Saving

#### 20.4.4.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ.HDQ\_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ\_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

This mode is recommended to reduce power consumption.

#### 20.4.4.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ.HDQ\_CTRL\_STATUS[5]) to 0 shuts off the functional clock (HDQ\_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

### 20.4.5 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see [Chapter 4, Power, Reset, and Clock Management](#)). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE\_L4\_ICLK and FUNC\_12M\_CLK belong to the L4 interconnect clock domain).

When the AUTO\_HDQ bit PRCM.CM\_AUTOIDLE1\_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

**CAUTION**

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

## 20.5 HDQ/1-Wire Basic Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

### 20.5.1 Module Initialization Sequence

#### 20.5.1.1 Mode Selection

MODE bit HDQ.HDQ\_CTRL\_STATUS[0] allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

#### 20.5.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ.HDQ\_CTRL\_STATUS[2] and the GO bit HDQ.HDQ\_CTRL\_STATUS[4]. The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ.HDQ\_CTRL\_STATUS[2] to 1 and the GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ.HDQ\_INT\_STATUS[0]) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ.HDQ\_CTRL\_STATUS register to check whether the presence pulse has been received before starting any transfer.

### 20.5.2 HDQ Protocol Basic Programming Model

#### 20.5.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ.HDQ\_TX\_DATA).

---

**Note:** Steps 2 and 3 can be performed simultaneously.

---

2. Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to indicate a write.
3. Set GO bit HDQ.HDQ\_CTRL\_STATUS[4] to start the transmission.
  - a. The hardware sends the byte from the TX write register.
  - b. In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
  - c. When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[2]). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
  - d. The GO bit HDQ.HDQ\_CTRL\_STATUS[4] is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

### 20.5.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ.HDQ\_TX\_DATA).
2. Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 0 and GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 and wait for the TX-complete interrupt.

---

**Note:** Steps 3 and 4 can be performed simultaneously.

---

3. Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 1 to indicate a read.
4. Write 1 to GO bit HDQ.HDQ\_CTRL\_STATUS[4] to initiate the read.
  - a. The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ.HDQ\_RX\_DATA). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ.HDQ\_CTRL\_STATUS[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
  - b. If a time-out occurs, the TIMEOUT bit HDQ.HDQ\_CTRL\_STATUS[0] is set.
  - c. Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (RXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[1]. If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
  - d. At the end of the read operation, the GO bit HDQ.HDQ\_CTRL\_STATUS[4] is cleared. It is also cleared if a time-out is detected.
5. The software must read the interrupt status register (HDQ.HDQ\_INT\_STATUS) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ.HDQ\_RX\_DATA) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

---

**Note:** In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

---

## 20.5.3 1-Wire Mode (SDQ) Basic Programming Model

### 20.5.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ.HDQ\_TX\_DATA).

---

**Note:** Steps 2 and 3 can be performed simultaneously.

---

2. Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 0 to indicate a write operation.
3. Set GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 to start the transmission.
  - a. The hardware sends the byte stored in the TX write register.
  - b. In a write operation, the TIMEOUT bit is always cleared.
  - c. When the operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ\_INT\_STATUS [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
  - d. The GO bit of the control and status register is cleared at the end of a write operation.
4. The software must read the interrupt status register (HDQ.HDQ\_INT\_STATUS) to clear the interrupt.

- Repeat step 1 through step 4 for each successive byte to write.

### 20.5.3.2 Read Operation

The read operation sequence is as follows:

- Write the address to the TX write register (HDQ.HDQ\_TX\_DATA).
- Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 0 and the GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 and wait for the TX-complete interrupt flag.
- Write the command value to the TX write register (HDQ.HDQ\_TX\_DATA).
- Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 0 and GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 and wait for the TX-complete interrupt flag.

---

**Note:** Steps 5 and 6 can be performed simultaneously.

---

- Set DIR bit HDQ.HDQ\_CTRL\_STATUS[1] to 1 to indicate a read.
- Set GO bit HDQ.HDQ\_CTRL\_STATUS[4] to 1 to start the transmission.
  - The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ.HDQ\_RX\_DATA). The first bit received is the LSB and the last bit is the MSB.
  - TIMEOUT bit HDQ.HDQ\_INT\_STATUS[0] is always cleared in a read operation.
  - When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
  - GO bit HDQ.HDQ\_CTRL\_STATUS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
- The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
- The software reads the RX receive buffer register (HDQ.HDQ\_RX\_DATA) to retrieve the read data from the slave.
- Repeat step 1 through step 8 for each successive byte.

### 20.5.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1\_WIRE\_SINGLE\_BIT bit HDQ.HDQ\_CTRL\_STATUS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[2]) for a write operation). Bit 0 of the RX register (HDQ.HDQ\_RX\_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ.HDQ\_TX\_DATA) contains the bit of data to be sent.

### 20.5.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ\_ICLK and functional clock: HDQ\_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ.HDQ\_SYSCONFIG[0] set to 1) provides a safe transfer (the module wakes up the HDQ\_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

### 20.5.4.1 Module Power-Down Mode

1. Before shutting off the HDQ\_FCLK, wait for an RX-complete or a TX-complete interrupt.
  - In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ\_INT\_STATUS [1]) generates an interrupt.
  - In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ\_INT\_STATUS [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/ address byte is sent; otherwise, the data is not written to the slave.

HDQ.HDQ\_INT\_STATUS must be read to clear the interrupt condition.
2. Set the CLOCKENABLE bit HDQ.HDQ\_CTRL\_STATUS[5] to 0 to disable the clock.  
Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

### 20.5.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see [Chapter 4, Power, Reset, and Clock Management](#)).

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ\_FCLK can be cut if the EN\_HDQ bit PRCM.CM\_FCLKEN1\_CORE [22] is set to 0 and no other modules require CORE\_12M\_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.  
In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ\_INT\_STATUS [1]) generates an interrupt.
2. Read the HDQ.HDQ\_INT\_STATUS to clear the read-complete interrupt flag.
3. Read the HDQ.HDQ\_RX\_DATA to retrieve the read data.
4. The HDQ\_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.  
In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ\_INT\_STATUS[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.
2. Read the HDQ.HDQ\_INT\_STATUS to clear the TX-complete interrupt flag.
3. The HDQ\_ICLK can be shut off by entering the system idle mode.

Concerning HDQ\_ICLK, two situations can occur:

- The clock is no longer required and EN\_HDQ bit PRCM.CM\_ICLKEN1\_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN\_HDQ bit, the software must follow the steps described in this section.
- AUTO\_HDQ bit PRCM.CM\_AUTOIDLE1\_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

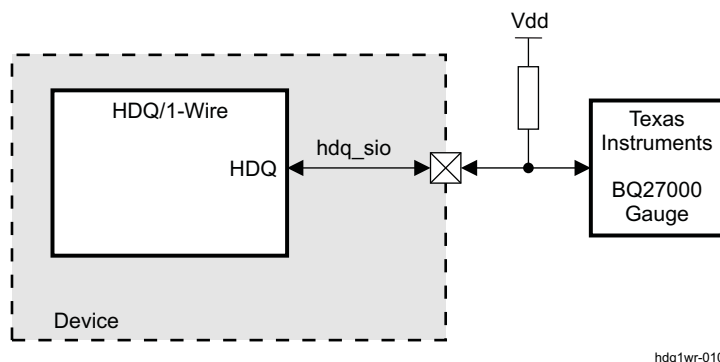

## 20.6 HDQ/1-Wire Use Cases and Tips

## 20.6.1 How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge

### 20.6.1.1 Environment

Figure 20-10 details the OMAP device connections with the BQ27000 gauge.

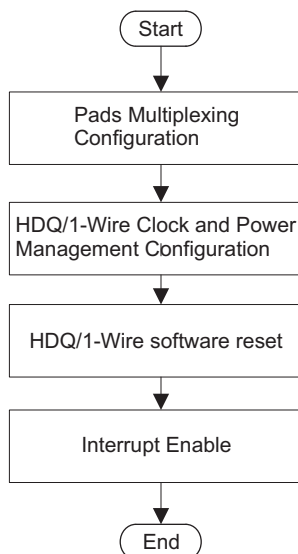

**Figure 20-10. Environment**

### 20.6.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. Figure 20-11 shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

**Figure 20-11. HDQ/1-Wire Configuration in HDQ Mode**

### 20.6.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

Table 20-3 shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

**Table 20-3. Registers Print for HDQ/1-Wire Configuration**

Register Name	Address	Value	Value description
SCM.CONTROL_PA DCONF_I2C3_SDA	0x 4800 21C4	0x0118 0100	Configure hdq_sio pad in mode 0

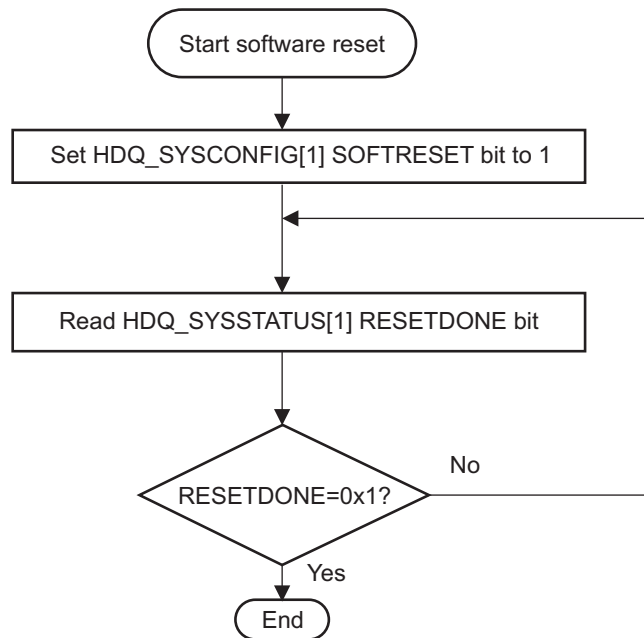

**Table 20-3. Registers Print for HDQ/1-Wire Configuration (continued)**

Register Name	Address	Value	Value description
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x0020 0000	Enable HDQ/1-Wire Functional clock
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x0020 0000	Enable HDQ/1-Wire Interface clock
HDQ_CTRL_STATUS	0x480B 200C	0x0000 0020	Enable clocks and select the HDQ mode
HDQ_SYSCONFIG	0x480B 2014	0x0000 0000	Module clock is free-running (Disable autoidle mode)

**20.6.1.4 HDQ/1-Wire Software Reset**

Perform a software reset as described in [Figure 20-12](#).

**Figure 20-12. Software Reset Flowchart**

hdq1wr-013

[Table 20-4](#) describes the registers to be configured for the HDQ/1-Wire software reset step.

**Table 20-4. Registers Print for HDQ/1-Wire Software Reset**

Register Name	Address	Value	Value description
HDQ_SYSCONFIG	0x480B 2014	0x0000 0002	Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware.
HDQ_SYSSTATUS	0x480B 2018	0x0000 0001	The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done.

**20.6.1.5 Interrupts Enable**

[Table 20-5](#) describes the registers to be configured for the interrupts enable step and the use case values.

**Table 20-5. Registers Print for HDQ/1-Wire Interrupts Enable**

Register Name	Address	Value	Value description
<a href="#">HDQ_CTRL_STATUS</a>	0x480B 200C	0x0000 0060	Enable Interrupts

### 20.6.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in [Section 20.5.2](#). Please, refer to this section to see how HDQ/1-Wire registers are configured for these operations.

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 gauge specification.

## 20.7 HDQ/1-Wire Register Manual

### 20.7.1 HDQ/1-Wire Instance Summary

Table 20-6 lists the HDQ/1-Wire instances.

**Table 20-6. Instance Summary**

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4K bytes

#### CAUTION

All reserved bits must be written with 0. There is no synchronization between the register clock domain and the state-machine domain. Therefore, the following rules must be observed when accessing the module registers:

- A read from the interrupt status register or the receive buffer register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the control and status register, no access to the TX data register or the control and status register is allowed until the processor has been interrupted by the module.
- Polling of the interrupt status register by software to determine whether an interrupt was generated is not allowed.
- No access to the module registers should be done after the software puts the module in power-down mode (by setting bit 5 of the control and status register to 0) except to re-enable the clock.

#### CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

### 20.7.2 HDQ/1-Wire Register Mapping Summary

Table 20-7 lists the HDQ/1-Wire registers.

**Table 20-7. HDQ/1-Wire Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	HDQ/1-Wire Physical Address
<a href="#">HDQ_REVISION</a>	R	32	0x000	0x480B2000
<a href="#">HDQ_TX_DATA</a>	RW	32	0x004	0x480B2004
<a href="#">HDQ_RX_DATA</a>	R	32	0x008	0x480B2008
<a href="#">HDQ_CTRL_STATUS</a>	RW	32	0x00C	0x480B200C

## **Multi-Channel Buffered Serial Port**

---

---

---

This chapter introduces the Multi-Channel Buffered Serial Port of the OMAP34xx multimedia device.

Topic	Page
21.1 McBSP Overview .....	2871
21.2 McBSP Environment .....	2875
21.3 McBSP Integration .....	2884
21.4 McBSP Functional Description .....	2905
21.5 McBSP Basic Programming Model.....	2940
21.6 McBSP Use Case and Tips.....	2969
21.7 McBSP Register Manual .....	2972

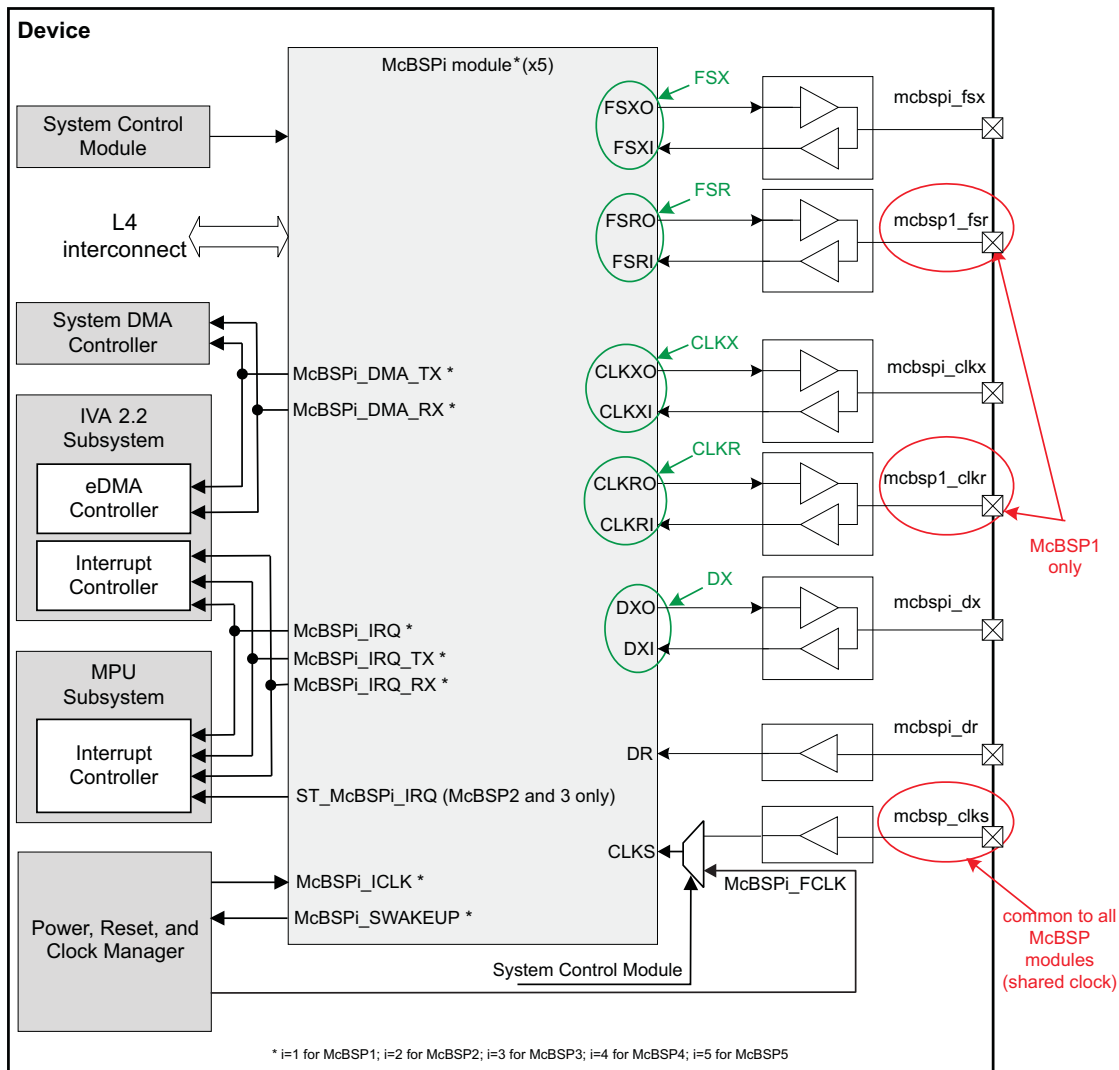

## 21.1 McBSP Overview

The multichannel buffered serial port (McBSP) provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec (TWL4030 device), etc. Because of its high level of versatility, it can accommodate to a wide range of peripherals and clocked frame oriented protocols (for details, see [Section 21.1.1](#)).

The device provides five instances of the McBSP module.

[Figure 21-1](#) shows the McBSP overview in the device.

**Figure 21-1. McBSP Highlight**

001

### 21.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 16- /8-bit access supported only by data registers

- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations (McBSP1, 3, 4, 5)
- 5K bytes (1024 × 32 bits for audio buffer + 256 × 32 bits for buffer) for each buffer for transmit/receive audio operations (McBSP2 only)
- Interrupts configurable in legacy mode (2 requests) or PRCM compliant (1 request)
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- SIDETONE core support: Audio loopback capability (McBSP2 and 3 only)
- Multidrop support
- Serial interface description
  - 6 pin configuration (McBSP 1 only)
  - 4 pin configuration (McBSP2, 3, 4, 5)
  - Full-duplex communication
  - Multichannel selection modes
    - Support to enable or block transfers in each of the channels
    - 128 channels for transmission and for reception
  - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
    - Inter-IC sound (I2S) compliant devices
    - Pulse code modulation (PCM) devices
    - Time division multiplexed (TDM) bus devices

**CAUTION**

McBSP modules do not offer support for  $\mu$ -law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
  - Independent clocking and framing for reception and for transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
  - Programmable polarity for frame-sync pulses and for clock signals

---

**Notes:**

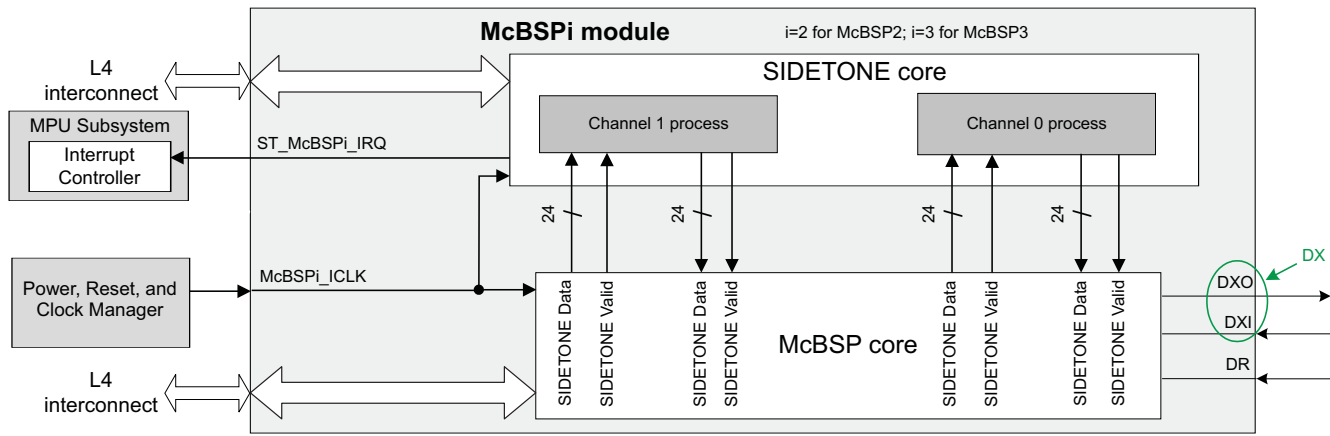

- McBSP modules do not support features such as re-transmit or re-receive of an erroneous frame or word.
  - McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.
- 

### 21.1.2 SIDETONE Core

The purpose of this section is to present the SIDETONE core implemented in McBSP2 and 3 modules. It is required that two of the audio input channels to be looped back, filtered, and mixed to the two corresponding audio output channels.

Data to be processed comes on two separate paths (one for each channel) through a simple interface. After filtering the data, gain is applied and outputted through a similar interface. For more details, see [Figure 21-2](#)).

**Figure 21-2. SIDETONE Core Architecture**

002

The SIDETONE core offers the following features:

- Filter coefficients are shared between the two channels (the filter coefficient is assumed to represent values in the range  $-1...+1$ )
- Gains are independent for the two channels (the gain coefficients are in the range  $-2...+2$ )
- The filter output is multiplied with the gain, and the result is rounded to output channel word width.
- The FIR filter length is 128 samples.
- Filtered loop back signals are added to the corresponding output signals, and saturation is applied if the result exceeds arithmetic range.
- Filter coefficients and gains are programmable:
  - Coefficients are changed while audio is stopped.
  - Gains are changed at any time (also during audio operation with SIDETONE enabled).

## 21.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

### 21.2.1 McBSP Functions

The device provides five instances of the McBSP module, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) Data
- McBSP2: Audio data with audio buffer and SIDETONE feature
- McBSP3: Bluetooth voice data with SIDETONE feature
- McBSP4: DBB voice data
- McBSP5: Midi data

[Table 21-1](#) describes the functions and the corresponding application fields.

**Table 21-1. Functions Description**

Function	Application field	Recommended McBSP module	Description
Control and Data	Digital Base Band (DBB) Data	McBSP1	Serial interface to transfer data
Audio Data	Audio Data with Audio Buffer	McBSP2	Audio interface to transfer audio data with Inter-IC Sound codec (I2S)
	Audio Data with Audio Buffer and SIDETONE feature		
	Midi Data	McBSP5	
Voice Data	Bluetooth Voice Data	McBSP3	Voice interface to transfer voice data with Pulse Code Modulation codec (PCM)
	Bluetooth Voice Data with SIDETONE feature		
	DBB Voice Data	McBSP4	

### 21.2.2 McBSP Signals Descriptions

The five McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6 pins configuration (McBSP 1 only) or 4 pins configuration (McBSP2, 3, 4, 5).

For a McBSP module with 6 pins configuration, an internal loop back capability between Transmitter and Receiver clock signals, and both frame synchronisation signals enables using the McBSP module with 4 pins configuration. The related internal multiplexers are controlled through the System Control Module on the device (see [Section 21.3](#)).

**Table 21-2. Input/Output Description**

Pin Name <sup>(1)</sup>	I/O <sup>(2)</sup>	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
mcbasp_clks	I	External clock (shared by all McBSP modules)	CLKS	-	ü	ü	ü
mcbaspi_dr	I	Receive serial data	DR	-	ü	ü	ü
mcbaspi_dx	I/O <sup>(3)</sup>	Transmit serial data	DX	0	ü	ü	ü
mcbaspi_clkx	I/O <sup>(3)</sup>	Transmit clock <sup>(4)</sup>	CLKX	0	ü	ü	ü
mcbaspi_fsx	I/O <sup>(3)</sup>	Transmit frame synchronization <sup>(5)</sup>	FSX	0	ü	ü	ü
mcbasp1_clkr	I/O <sup>(3)</sup>	Receive clock <sup>(6)</sup>	CLKR	1	ü		
mcbasp1_fsr	I/O <sup>(3)</sup>	Receive frame synchronization <sup>(7)</sup>	FSR	0	ü		

(1) I = 1 to 5

(2) I = Input; O = Output

(3) For details of the input/output selection, see [Section 21.2.3.1](#).

(4) This signal is also used as CLKR when it is configured as output.

(5) This signal is also used as FSR when it is configured as output.

(6) This signal is also used as CLKX when it is configured as input.

(7) This signal is also used as FSX when it is configured as input.

- The mcbasp\_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 21.4.3](#)). The CLKS signal of the McBSP modules is linked to an external signal through the mcbasp\_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see [Section 21.3](#).
- Data are transmitted to external devices interfacing with McBSP modules via the mcbaspi\_dx pin. Data from those devices are received on the mcbaspi\_dr pin.

**Note:** The mcbaspi\_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated via the following pins: mcbaspi\_clkx (transmit clock), mcbasp1\_clkr (receive clock), mcbaspi\_fsx (transmit frame-sync), and mcbasp1\_fsr (receive frame-sync).

**CAUTION**

External pins mcbasp1\_clkr and mcbasp1\_fsr are connected to pads only for McBSP1 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbaspi\_clkx and mcbaspi\_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Both reception and transmission use the same clock signal and the same frame synchronization signal.

**21.2.3 McBSP Functions Description****21.2.3.1 McBSP Modes**

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

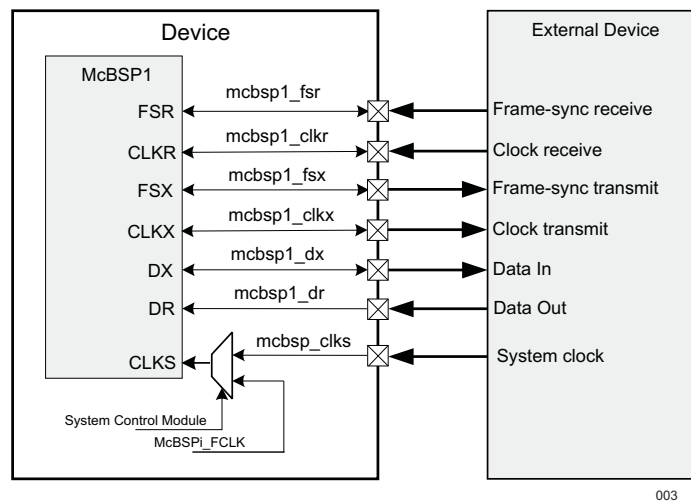

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

1. Transmit and receive master mode
2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

**Note:** If the McBSP module has a serial interface with 4 pins configuration (McBSP2, 3, 4, 5), only modes 1 or 2 are possible.

Figure 21-3 shows the connection between the McBSP1 module (6 pins configuration) and an external device in transmit master mode and receive slave mode.

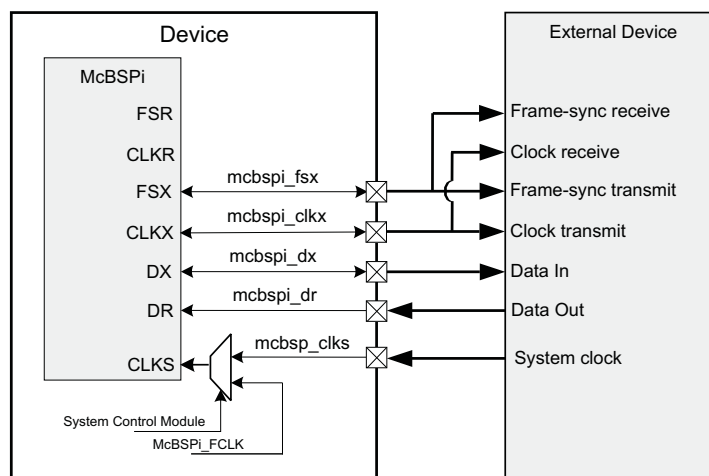

Figure 21-3. Mode Overview of McBSP1 Module

003

Figure 21-4 shows the connection between the McBSPi module, with I = 2, 3, 4 or 5 (4 pins configuration) and an external device in transmit and receive master mode.

Figure 21-4. Mode Overview of McBSPi Module

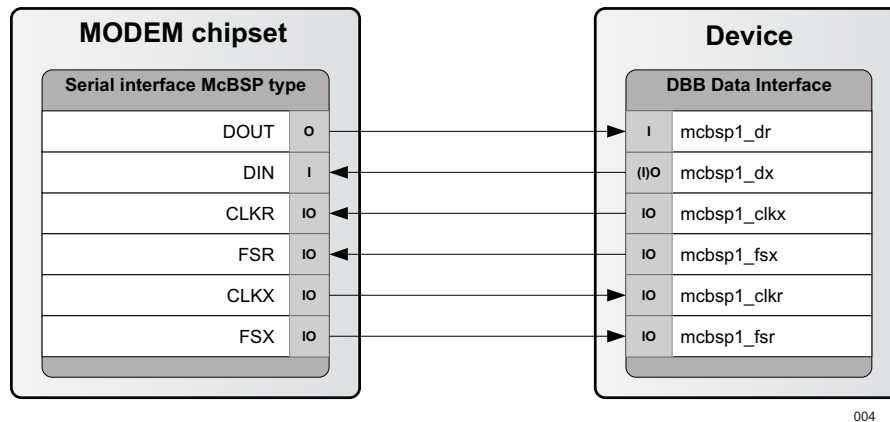

067

### 21.2.3.2 McBSP Functions

#### 21.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 21-5 shows typical connections between device and modem chipset to illustrate DBB data application.

Figure 21-5. DBB Data Application

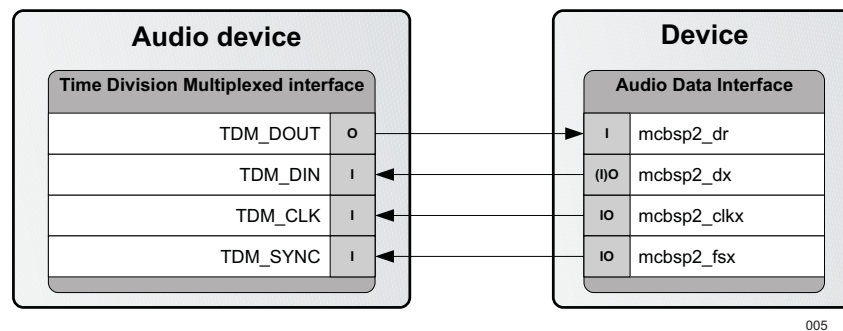

In Figure 21-5, the McBSP1 module is configured in transmit master mode and in receive slave mode.

#### 21.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 21-6 shows typical connections between device and a typical device of analog audio interface (TWL4030 device) to illustrate Audio Data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 21-6. Audio Data Application

In Figure 21-6, the McBSP2 module is configured in transmit and receive master mode.

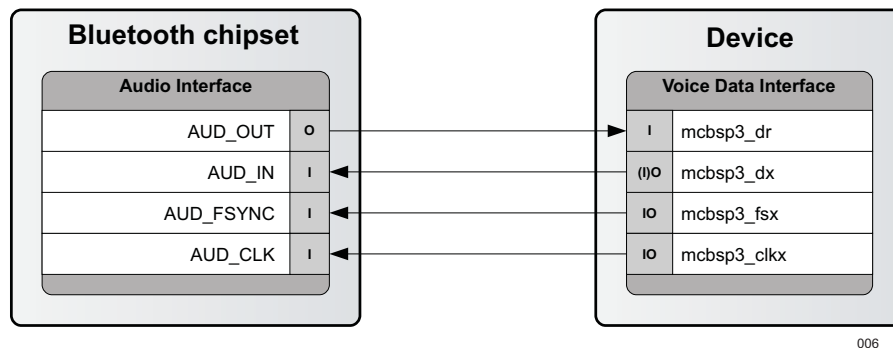

#### 21.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be either modem chipsets, Bluetooth chipsets or others devices with voice data interface.

Figure 21-7 shows typical connections between device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 21-7. Voice Data Application

In Figure 21-7, the McBSP3 module is configured in transmit and receive master mode.

## 21.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

### 21.2.4.1 Words, Frames, and Phases Definitions

#### 21.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field and McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field, McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field and McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field) and can be 8, 12, 16, 20, 24 or 32 bits (see Section 21.4.2.3). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP\_PCR\_REG).

For more information, see Section 21.4.2.4.

#### 21.2.4.1.2 Frames

One or more words (max 128) are transferred in a group called a frame. The McBSP module can transmit / receive a maximum of 128 words per frame, programmable via bits field of transmit and receive control registers (McBSPi.MCBSPLP\_XCR1\_REG/McBSPi.MCBSPLP\_XCR2\_REG and McBSPi.MCBSPLP\_RCR1\_REG/McBSPi.MCBSPLP\_RCR2\_REG). For more details, see Section 21.4.2.3.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP\_PCR\_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP\_XCR2\_REG and McBSPi.MCBSPLP\_RCR2\_REG). For more information, see [Section 21.4.4.6.3](#) and [Section 21.4.4.3.3](#).

### 21.2.4.1.3 Phases

The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual phase frame is that the number of words per phase must be set to one for both first and second phase. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 21.4.2.4](#).

[Figure 21-8](#) shows signal activity for two possible reception/transmission scenarios.

**Figure 21-8. McBSP Reception/Transmission Signal Activity**

## 21.2.4.2 Serial Protocol and Data Formats

### 21.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

### 21.2.4.2.2 Data Format

[Figure 21-9](#) shows typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see [Section 21.4](#) and [Section 21.5](#).

**Figure 21-9. Serial Data Formats**

**21.2.4.3 Audio Protocol and Data Formats**

**21.2.4.3.1 Protocol**

The I2S protocol is used to send and receive audio data from 8 KHz up to 48 KHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (Supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1 and 48 KHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

**21.2.4.3.2 Data Formats**

The I2S protocol supports TDM, I2S, left justified, and right justified data formats.

Bits of each word (sample) are clocked using clock signal. For each word, MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

**21.2.4.3.2.1 TDM Data Format**

[Figure 21-10](#) shows that each frame of TDM data format is composed of four words (or channels).

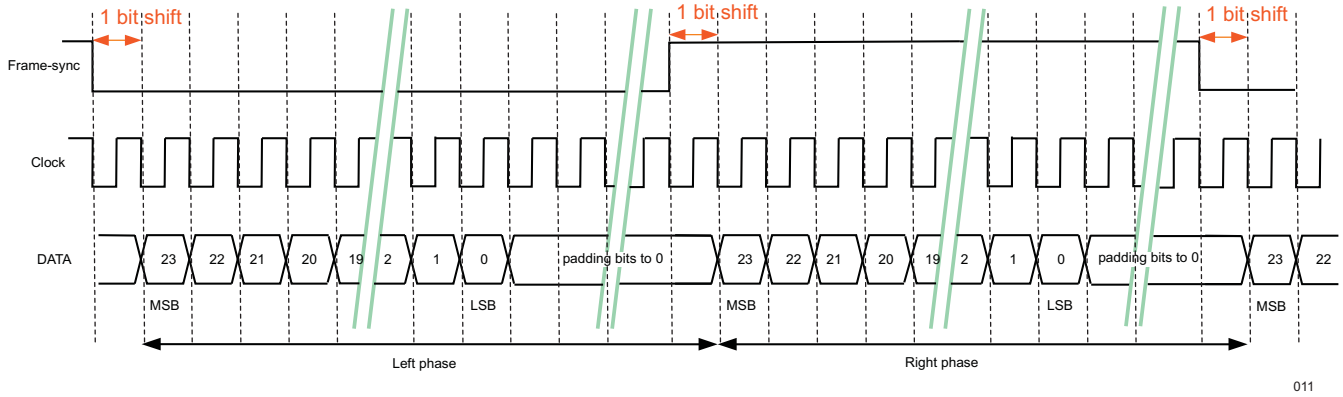

**Figure 21-10. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits**

### 21.2.4.3.2 I2S Data Format

Figure 21-11 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

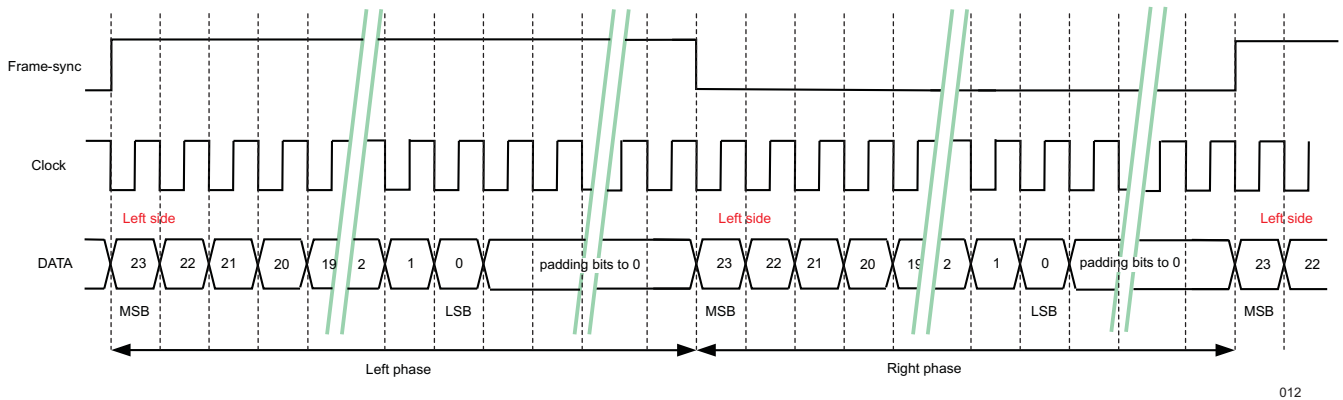

**Figure 21-11. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits**

### 21.2.4.3.2.3 Left Justified Data Format

Figure 21-12 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

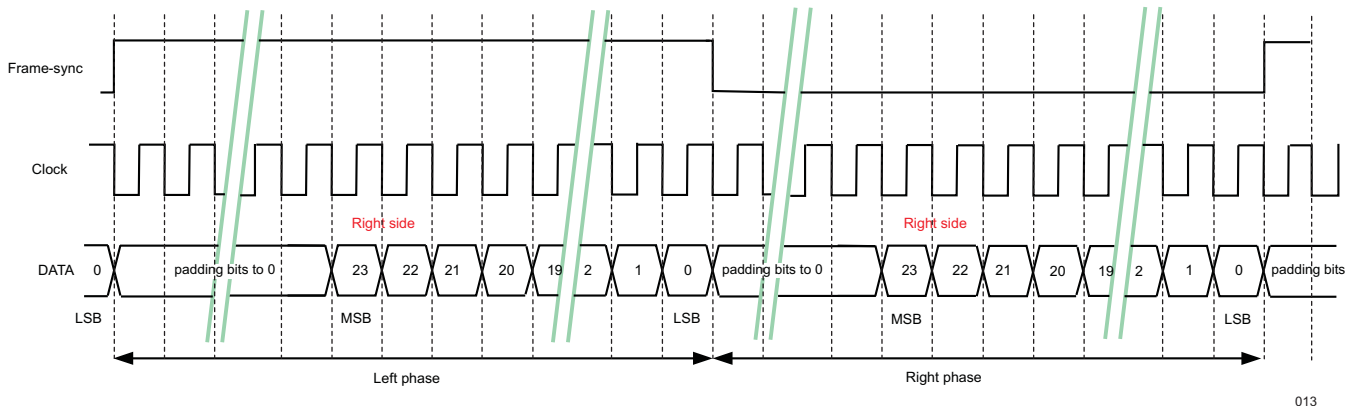

**Figure 21-12. Left Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits**

### 21.2.4.3.2.4 Right Justified Data Format

Figure 21-13 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

**Figure 21-13. Right Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits**

21.2.4.4 Voice Protocol and Data Formats

21.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8 kHz (default narrowband mode) or 16 kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using PCM clock signal, with MSB first.

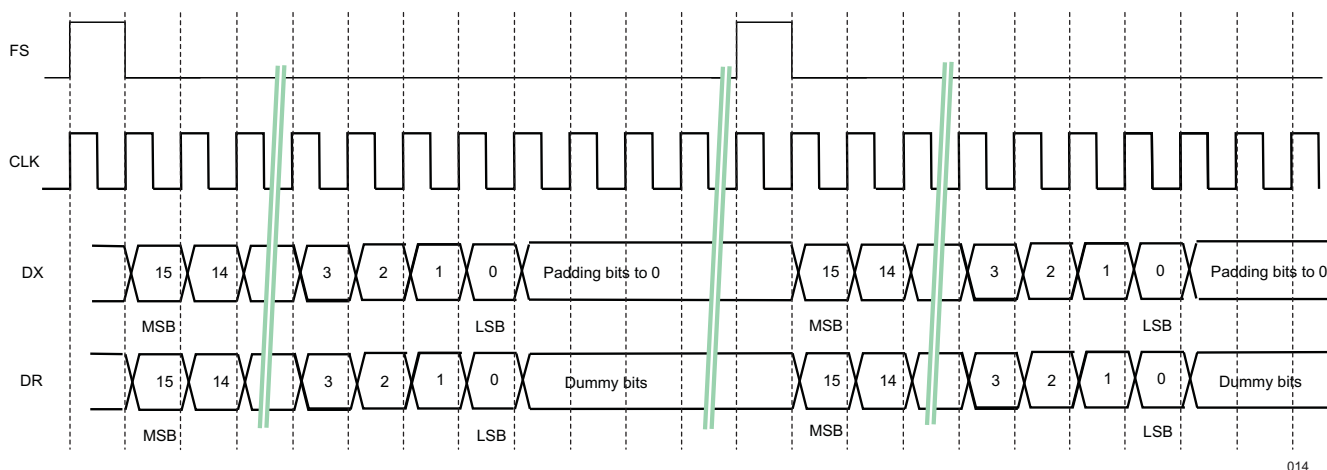

21.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For these both modes, it has two types of operations: Mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of clock signal, and the frame-synchronization polarity.

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

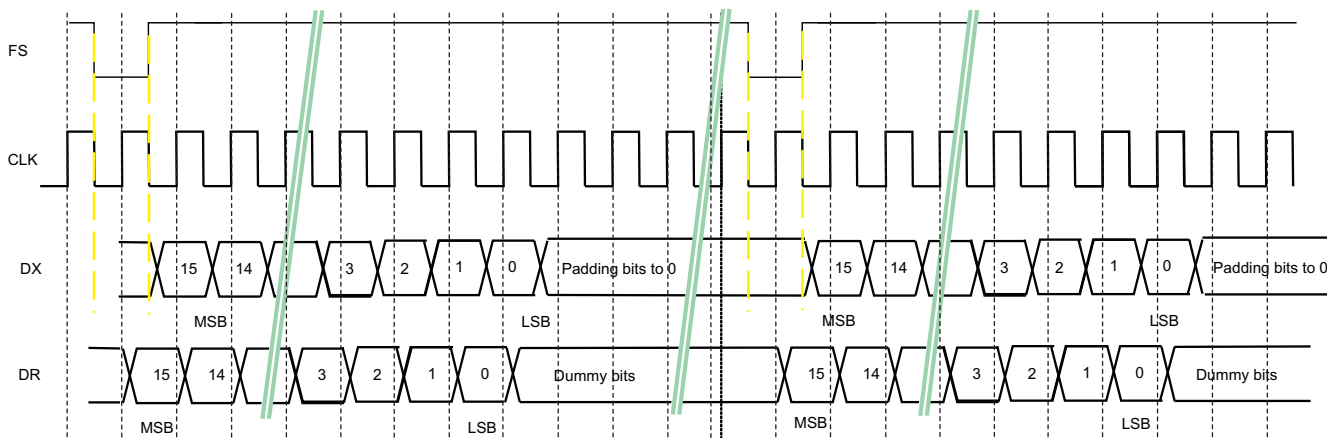

Figure 21-14 and Figure 21-15 shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

### 21.3 McBSP Integration

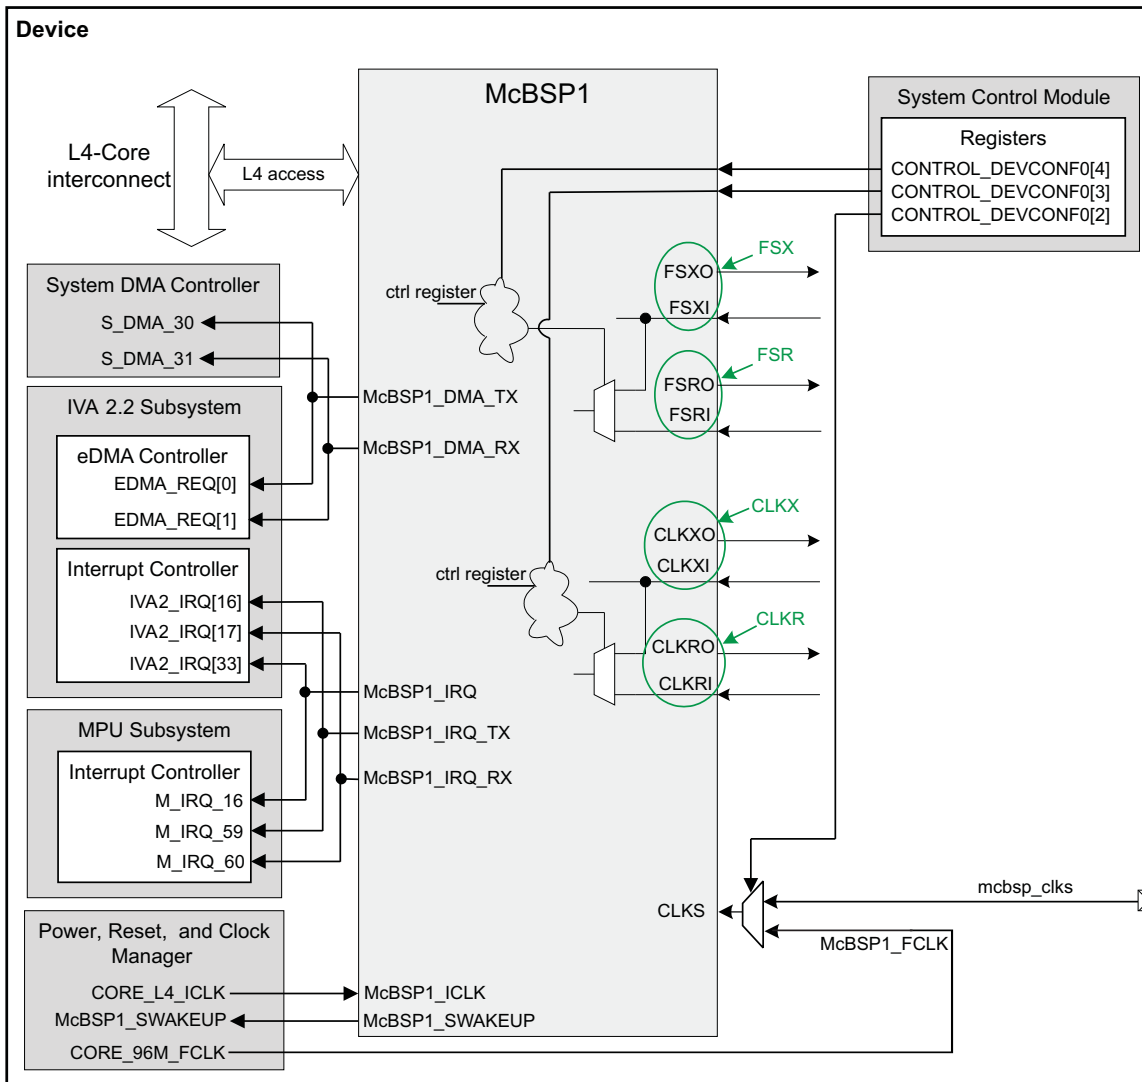

This section describes the McBSP modules integration inside the device and all the details about signal source controls, clocks, resets, power management, and hardware requests.

McBSP modules are divided into 2 families: McBSP modules that are gated in CORE domain (McBSP1 and 5), and McBSP modules that are gated in PER domain (McBSP2, 3, and 4).

For more details on CORE and PER domain, see [Chapter 4, Power, Reset and Clock Management](#).

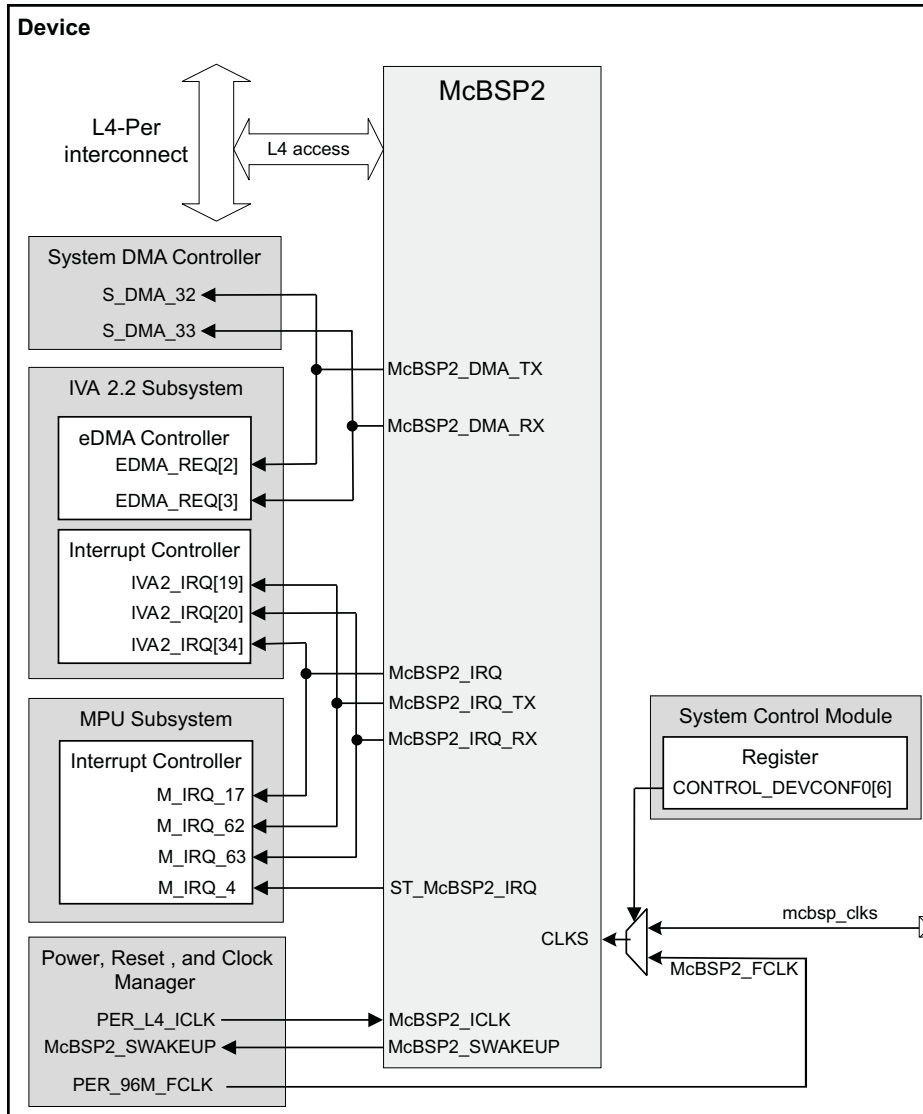

[Figure 21-16](#) through [Figure 21-20](#) highlight the integration of the McBSP modules in the device including interrupt handlers, DMA requests, clock generators, and interconnections.

017

### 21.3.1 Signal Source Control

The FSR, CLKR and CLKS signals sources are defined by the system control module. The control registers of the system control module are used to select these signals sources.

#### 21.3.1.1 McBSP1 Module (6 Pins Configuration)

The MCBSP1\_CLKS bit of the CONTROL.DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to '0', the CLKS source is from the CORE\_96M\_FCLK
- When set to '1', the CLKS source is from the mcbasp\_clks pin

The MCBSP1\_CLKR bit of the CONTROL\_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1\_FSR bit of the CONTROL\_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

### 21.3.1.2 McBSP2, 3, 4, and 5 modules (4 pins configuration)

For these McBSPi modules, there are no external mcbspi\_clkr and mcbspi\_fxr pins (i=2, 3, 4, and 5).

Consequently, the system control module controls only the internal connection of CLKS input signals. The settings are explained in [Section 21.3.2.2.2](#), [Section 21.3.2.2.3](#), [Section 21.3.2.2.4](#), and [Section 21.3.2.2.5](#).

## 21.3.2 Clocking, Reset, and Power Management Scheme

### 21.3.2.1 Power Domain

McBSP1 and McBSP5 modules belong to the CORE domain, whereas the McBSP2, McBSP3, and McBSP4 modules belong to the PER (peripheral) domain. This separation of McBSP modules in two power domain allows major part of the device to be switched off while keeping active McBSP2, 3, and 4.

For more information about these power domains, see [Chapter 4, Power Reset and Clock Management](#).

### 21.3.2.2 Clocks

There are two clock domains in the McBSP module:

- Functional clock domain
- Interface clock domain

**Table 21-3. Clocking Signals Input to McBSP Module**

Type	Name	Source	Description
Interface	McBSPi_ICLK	PER_L4_ICLK (McBSP2, 3, 4) <sup>(1)</sup>	The L4 interface clock is used for the module internal L4 interconnect slave interface and all depending parts of the Interface clock domain.
		CORE_L4_ICLK (McBSP1, 5) <sup>(1)</sup>	
Functional	CLKS	PER_96M_FCLK (McBSP2, 3, 4) <sup>(1)</sup>	McBSP module is running using either a functional clock generated internally (master mode) or supplied from its serial interface (slave mode) for the internal logic. Internal registers select the source of the functional clock and the divider ratio to apply.
		CORE_96M_FCLK (McBSP1, 5) <sup>(1)</sup>	
		mcbbsp_clks (external source common to all McBSP modules)	
Functional	CLKX	mcbspi_clkx (external source)	Functional clock after division in any mode is limited to maximum frequency divided by 2.
Functional	CLKR (McBSP1 only)	mcbbsp1_clkr (external source)	

<sup>(1)</sup> For more information about these sources, see [Chapter 4, Power Reset and Clock Management](#).

#### 21.3.2.2.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (McBSP1\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP1 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP1.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the McBSP1.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP1 module is linked to an internal clock (CORE\_96M\_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp\_clks pin of the device boundary. The McBSP1\_CLKS bit of the CONTROL.CONTROL\_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- 0: The CLKS source is from the CORE\_96M\_FCLK.

- 1: The CLKS source is from the mcbasp\_clks pin.

For more information on this register, see [Chapter 7, System Control Module](#).

---

**Note:** When the McBSP1 module does not require the PRCM functional clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP1 bit (PRCM.CM\_FCLKEN1\_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off CORE\_96M\_FCLK clock are met the PRCM automatically launches a **Hardware** handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see [Chapter 4, Power Reset and Clock Management](#).

---

The CLKX and CLKR signals are connected either by mcbasp1\_clkx or mcbasp1\_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP1\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is the CORE\_L4\_ICLK signal.

---

**Note:** When the McBSP1 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP1 bit (PRCM.CM\_ICLKEN1\_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off CORE\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see [Chapter 4, Power Reset and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE1\_CORE[9] register AUTO\_MCBSP1 bit set to 1). In this case, McBSP1\_ICLK follows the CORE\_L4 clock domain behavior on the device. For more information, see [Chapter 4, Power Reset and Clock Management](#).

### 21.3.2.2.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP2\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP2 module, the functional clock comes from the CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP2.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the McBSP2.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP2 module is linked to an internal clock (PER\_96M\_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbasp\_clks pin of the device boundary. The McBSP2\_CLKS bit of the CONTROL.CONTROL\_DEVCONF0[6] register is used to select the McBSP2 module CLKS signal source:

- 0: The CLKS source is from the PER\_96M\_FCLK.
- 1: The CLKS source is from the mcbasp\_clks pin.

For more information, see [Chapter 7, System Control Module](#).

**Note:** When the McBSP2 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP2 bit (PRCM.CM\_FCLKEN\_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_96M\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see [Chapter 4, Power Reset and Clock Management](#).

Only, the CLKX signal is connected by mcbbsp2\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP2\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER\_L4\_ICLK signal.

**Note:** When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP2 bit (PRCM.CM\_ICLKEN\_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see [Chapter 4, Power Reset and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE\_PER[0] register AUTO\_MCBSP2 bit set to 1). In this case, McBSP2\_ICLK follows the CORE\_L4 clock domain behavior on the device. For more information, see [Chapter 4, Power Reset and Clock Management](#).

### 21.3.2.2.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP3\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP3 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP3.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the McBSP3.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP3 module is linked to an internal clock (PER\_96M\_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp\_clks pin of the device boundary. The McBSP3\_CLKS bit of the CONTROL.CONTROL\_DEVCONF1[0] register is used to select the McBSP3 module CLKS signal source:

- 0: The CLKS source is from the PER\_96M\_FCLK.
- 1: The CLKS source is from the mcbbsp\_clks pin.

For more information, see [Chapter 7, System Control Module](#).

**Note:** When the McBSP3 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP3 bit (PRCM.CM\_FCLKEN\_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_96M\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see [Chapter 4, Power Reset and Clock Management](#).

Only, the CLKX signal is connected by mcbbsp3\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP3\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER\_L4\_ICLK signal.

**Note:** When the McBSP3 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP3 bit (PRCM.CM\_ICLKEN\_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see [Chapter 4, Power Reset and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE\_PER[1] register AUTO\_MCBSP3 bit set to 1). In this case, McBSP3\_ICLK follows the PER\_L4 clock domain behavior on the device. For more information, see [Chapter 4, Power Reset and Clock Management](#).

#### 21.3.2.2.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP4\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP4 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP4.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP4.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP4 module is linked to an internal clock (PER\_96M\_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp\_clks pin of the device boundary. The MCBSP4\_CLKS bit of the CONTROL.CONTROL\_DEVCONF1[2] register is used to select the McBSP4 module CLKS signal source:

- 0: The CLKS source is from the PER\_96M\_FCLK.
- 1: The CLKS source is from the mcbbsp\_clks pin.

For more information, see [Chapter 7, System Control Module](#).

**Note:** When the McBSP4 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP4 bit (PRCM.CM\_FCLKEN\_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_96M\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see [Chapter 4, Power Reset and Clock Management](#).

Only the CLKX signal is connected by mcbbsp4\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP4\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the PER\_L4\_ICLK signal.

**Note:** When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP4 bit (PRCM.CM\_ICLKEN\_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off PER\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see [Chapter 4, Power Reset and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE\_PER[2] register AUTO\_MCBSP4 bit set to 1). In this case, McBSP4\_ICLK follows the PER\_L4 clock domain behavior on the device. For more information, see [Chapter 4, Power Reset and Clock Management](#).

### 21.3.2.2.5 McBSP5 Clocks

The McBSP5 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP5\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 21.4](#)). For McBSP5 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP5.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP5.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP5 module is linked to an internal clock (CORE\_96M\_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbbsp\_clks pin of the device boundary. The MCBSP5\_CLKS bit of the CONTROL.CONTROL\_DEVCONF1[4] register is used to select the McBSP5 module CLKS signal source:

- 0: The CLKS source is from the CORE\_96M\_FCLK.
- 1: The CLKS source is from the mcbbsp\_clks pin.

For more information, see [Chapter 7, System Control Module](#).

**Note:** When the McBSP5 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP5 bit (PRCM.CM\_FCLKEN1\_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off CORE\_96M\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see [Chapter 4, Power Reset and Clock Management](#).

Only, the CLKX signal is connected by mcbbsp5\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP5\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP5 L4 interface and McBSP5 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 21.4.3](#)). Its source is either the CORE\_L4\_ICLK signal.

**Note:** When the McBSP5 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN\_MCBSP5 bit (PRCM.CM\_ICLKEN1\_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see [Chapter 4, Power Reset and Clock Management](#).

At PRCM level, when all the conditions to shut-off CORE\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see [Chapter 4, Power Reset and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE1\_CORE[10] register AUTO\_MCBSP5 bit set to 1). In this case, McBSP5\_ICLK follows the CORE\_L4 clock domain behavior on the device. For more information, see [Chapter 4, Power Reset and Clock Management](#).

### 21.3.2.2.6 SIDETONE Clock

The SIDETONE feature, in the McBSP2 and McBSP3 modules, is clocked only by an interface clock (McBSP2\_ICLK or McBSP3\_ICLK).

#### CAUTION

See [Section 21.3.2.2.2](#) and [Section 21.3.2.2.3](#) for information on McBSP2\_ICLK and McBSP3\_ICLK clocks.

When the SIDETONE feature does not require the clock anymore, the software can disable it at the SIDETONE level by setting the McBSPi.ST\_SYSCONFIG\_REG[0] AUTOIDLE bit in SIDETONE registers. To conserve power, when SIDETONE feature is not active or there is no activity on SIDETONE feature, the McBSPi\_ICLK clock supports an automatic gating that is enabled or disabled by setting the McBSPi.ST\_SYSCONFIG\_REG[0] AUTOIDLE bit.

- When this bit is asserted (set to 1), the McBSPi\_ICLK clock auto-gating is enabled and this clock is disabled internally to the SIDETONE feature, thus reducing power consumption, but not to the McBSP module that contains this feature.  
After reset, the automatic clock gating is enabled; thus, this bit must be disabled by software for activated SIDETONE feature.
- When this bit is set to 0, the McBSPi\_ICLK clock auto-gating is disabled and this clock is enabled. The SIDETONE feature can be used normally.

### 21.3.2.3 Hardware and Software Reset

McBSP1 and McBSP5 modules belong to the CORE domain and their reset signal is the CORE\_RST signal from the PRCM module, whereas McBSP2, 3 and 4 modules belong to the PER domain and their reset signal is the PER\_RST signal from the PRCM module.

For more details about these signals, see [Chapter 4, Power Reset and Clock Management](#).

**Table 21-4. Software Reset Signals to All McBSP Modules**

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver, including the RB.
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB.
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG

For more details about these signals, see [Section 21.7](#). See [Section 21.5.1.1](#), for a complete description of the McBSP initialization procedure.

### 21.3.2.4 Power Management

#### 21.3.2.4.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- **ACTIVE state:** The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- **IDLE state:** As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wake-up features) and its clocks are likely to be switched off at PRCM level.

---

**Note:** Idle request and idle acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

---

#### 21.3.2.4.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module ( that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPLP\_SYSCONFIG\_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- **Force Idle mode (SIDLEMODE bit = 0x0):** An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity), interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

**CAUTION**

In Force Idle mode, the wake-up feature is inhibited.

**CAUTION**

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgment to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See [Section 21.3.2.4.4](#)) and external signals.

---

**Note:** The value `MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3]` SIDLEMODE field = 0x3 must not be used.

---

When configured in Smart Idle mode, McBSP module also offers an additional granularity on `McBSPi_FCLK` and `McBSPi_ICLK` gating. `MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8]` CLOCKACTIVITY bit field is used to determine which clock will be shut down (`McBSPi_FCLK`, `McBSPi_ICLK`, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM idle request will be tested. As an example, if `McBSPi_FCLK` is said not to be shut down upon a PRCM idle request, this means McBSP module will only consider `McBSPi_ICLK` and the associated pending activities before acknowledging the request.

---

**Note:** Some of McBSP features are associated to `McBSPi_ICLK` and others to `McBSPi_FCLK`. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an idle request. For more information, see [Section 21.3.2.4.4](#).

---

[Table 21-5](#) lists the value of the bit field and indicates if the interface (`McBSPi_ICLK`) and PRCM functional (`McBSPi_FCLK`) clocks can be switched-off or not when an idle request is received by McBSP module.

**Table 21-5. State of Clocks When the Module is in Idle State**

CLOCKACTIVITY Value	Interface Clock ( <code>McBSPi_ICLK</code> )	PRCM Functional Clock ( <code>CORE_96M_FCLK</code> or <code>PER_96M_FCLK</code> )
0b00	OFF	OFF
0b01	OFF	ON
0b10	ON	OFF
0b11	ON	ON

- Note:** OFF means this clock can be switched-off.  
ON means this clock must be maintained during wake up period.

### CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between McBSPi.MCBSPLP\_SYSCONFIG\_REG[9:8] CLOCKACTIVITY bit field and PRCM 96M\_FCLK and L4\_ICLK control bits (for more information about clocks, see [Section 21.3.2.2, Clocks](#)). If McBSP module is disabled in both CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

The software can disable all clocks at the McBSP module level by setting the IDLE\_EN bit in McBSPi.MCBSPLP\_PCR\_REG[14] registers. The IDLE\_EN bit allows stopping all the clocks in the McBSP module (legacy):

- When set to '0', the McBSP module is running
- When set to '1', the clocks in the McBSP module are shut off when both IDLE\_EN =1 and his power domain is in idle mode.

#### 21.3.2.4.3 Wake-Up Capability

When configured in Smart Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP\_SYSCONFIG\_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to '0', wake up capability is disabled
- Set to '1', wake up capability is enabled

The McBSPi\_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP\_WAKEUPEN\_REG register.

#### 21.3.2.4.3.1 Receive Wake-up

There are 4 receive possible wake up configurations:

- McBSPi.MCBSPLP\_WAKEUPEN\_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP\_THRSH1\_REG register. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[3] RRDY bit changes from '0' to '1', indicating that received data is ready to be read).
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[2] REOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[1] RFSREN bit: The McBSP module sends a McBSPi\_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.

- McBSPi.MCBSPLP\_WAKEUPEN\_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR bit changes from '0' to '1', indicating that a receive error occurred).

#### 21.3.2.4.3.2 Transmit Wakeup

For transmit, there are also 5 possible wake-up configuration scenarios:

- McBSPi.MCBSPLP\_WAKEUPEN\_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP\_THRSH2\_REG register. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[10] XRDY bit changes from '0' to '1', indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[8] XFSXEN bit: The McBSP module sends a McBSPi\_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR bit changes from '0' to '1', indicating that a transmit error occurred).

#### 21.3.2.4.3.3 Notes

When mcbbsp1\_fsr/mcbspi\_fsx pins is configured as an output, the FSR/FSX wake-up generation makes no sense (the module cannot be in Smart Idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbbsp1\_fsr/mcbspi\_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake up capability in this mode is not available.

#### 21.3.2.4.4 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is shown in [Table 21-6](#) :

In this table, the CLKRM bit is in the McBSPi.MCBSPLP\_PCR\_REG register on position 8, CLKXM bit in the McBSPi.MCBSPLP\_PCR\_REG[9] register, and CLOCKACTIVITY bit in the McBSPi.MCBSPLP\_SYSCONFIG\_REG[9:8] register.

The value X signifies that the bit value is not significant.

**Table 21-6. McBSP Smart Idle Mode Configuration Behavior**

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	outside	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: <ul style="list-style-type: none"> <li>• The transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (CLKR is not connected to the CLKX input pin).</li> <li>• Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST)</li> </ul> The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	Receive master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: The receive part is disabled (RDISABLE) or under software reset (RRST) The Idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKX	0bXX	When CLKX is used as source (functional clock is provided from outside) then the module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

**Table 21-6. McBSP Smart Idle Mode Configuration Behavior (continued)**

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and Receive Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	

**Note:** The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and mcbasp1\_fsr/mcbspi\_fsx pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

### 21.3.3 Hardware Requests

#### 21.3.3.1 DMA Requests

The DMA requests are shared between the IVA2.2 subsystem DMA controller (eDMA) and system DMA controller (sDMA). Each of the five McBSP modules can generate two DMA events:

- McBSPi\_DMA\_TX : McBSPi module transmit request
- McBSPi\_DMA\_RX : McBSPi module receive request

The following table summarizes the DMA events with the mapping on both DMA controllers.

**Table 21-7. McBSP DMA Requests**

Request Name	Mapping	Destination	Description
McBSP1_DMA_TX	EDMA_REQ[0] S_DMA_30	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP1_DMA_RX	EDMA_REQ[1] S_DMA_31	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP2_DMA_TX	EDMA_REQ[2] S_DMA_32	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP2_DMA_RX	EDMA_REQ[3] S_DMA_33	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP3_DMA_TX	EDMA_REQ[4] S_DMA_16	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP3_DMA_RX	EDMA_REQ[5] S_DMA_17	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP4_DMA_TX	EDMA_REQ[6] S_DMA_18	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP4_DMA_RX	EDMA_REQ[7] S_DMA_19	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP5_DMA_TX	EDMA_REQ[8] S_DMA_20	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP5_DMA_RX	EDMA_REQ[9] S_DMA_21	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request

#### 21.3.3.2 Interrupt Requests

##### 21.3.3.2.1 McBSP Interrupt Requests

Each of the five McBSP modules can generate three interrupts, shared between the MPU subsystem and IVA2.2 subsystem interrupt controllers:

- McBSPi\_IRQ: McBSPi module common interrupt request
- McBSPi\_IRQ\_TX: McBSPi module transmit interrupt request
- McBSPi\_IRQ\_RX: McBSPi module receive interrupt request

The following tables list the interrupt requests with the mapping.

**Table 21-8. McBSP Common Interrupt Requests**

Request Name	Mapping	Destination
McBSP1_IRQ	IVA2_IRQ[33] M_IRQ_16	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ	IVA2_IRQ[34] M_IRQ_17	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ	IVA2_IRQ[35] M_IRQ_22	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ	IVA2_IRQ[36] M_IRQ_23	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

**Table 21-8. McBSP Common Interrupt Requests (continued)**

Request Name	Mapping	Destination
McBSP5_IRQ	IVA2_IRQ[37] M_IRQ_27	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

**Table 21-9. McBSP Transmit Interrupt Requests**

Request Name	Mapping	Destination
McBSP1_IRQ_TX	IVA2_IRQ[16] M_IRQ_59	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_TX	IVA2_IRQ[19] M_IRQ_62	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_TX	IVA2_IRQ[21] M_IRQ_89	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_TX	IVA2_IRQ[23] M_IRQ_54	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_TX	IVA2_IRQ[25] M_IRQ_81	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

**Table 21-10. McBSP Receive Interrupt Requests**

Request Name	Mapping	Destination
McBSP1_IRQ_RX	IVA2_IRQ[17] M_IRQ_60	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_RX	IVA2_IRQ[20] M_IRQ_63	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_RX	IVA2_IRQ[22] M_IRQ_90	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_RX	IVA2_IRQ[24] M_IRQ_55	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_RX	IVA2_IRQ[26] M_IRQ_82	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

An event can generate an interrupt request when the corresponding mask bit in the `McBSPi.MCBSPLP_IRQENABLE_REG` register is set to '1'.

[Table 21-11](#) and [Table 21-12](#) summarize the events causing the generation of an interrupt request.

**Table 21-11. McBSP Transmit Interrupt Events**

Event Name	Status Bit	Mask Bit	Description
Transmit buffer empty at end of frame	McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF	McBSPi.MCBSPLP_IRQENABLE_REG [14] XEMPTYEOFEN	This event happens when a complete frame was transmitted and the transmit buffer is empty .
Overflow	McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [12] XOVFLEN	This event happens when transmit data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [11] XUNDFLEN	This event happens when transmit data buffer is empty and a new data is required to be transmitted.
Threshold reached	McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY	McBSPi.MCBSPLP_IRQENABLE_REG [10] XRDYEN	This event happens when the transmit buffer free locations are equal or above the THRS2_REG value.
End of Frame	McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF	McBSPi.MCBSPLP_IRQENABLE_REG [9] XEOFLEN	This event happens when a complete frame was transmitted.
Frame-sync	McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX	McBSPi.MCBSPLP_IRQENABLE_REG [8] XFSXEN	This event happens when a new transmit frame synchronization is asserted.

**Table 21-11. McBSP Transmit Interrupt Events (continued)**

Event Name	Status Bit	Mask Bit	Description
Frame-sync error	McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR	McBSPi.MCBSPLP_IRQENABLE_REG [7] XSYNCERREN	This event happens when a transmit frame synchronization error is detected.

**Table 21-12. McBSP Receive Interrupt Events**

Event Name	Status bit	Mask bit	Description
Overflow	McBSPi.MCBSPLP_IRQS TATUS_REG[5] ROVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_ REG[5] ROVFLFN	This event happens when receive data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQS TATUS_REG[4] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_ REG[4] RUNDFFLN	This event happens when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined.
Threshold reached	McBSPi.MCBSPLP_RQS TATUS_REG[3] RRDY	McBSPi.MCBSPLP_IRQENABLE_ REG[3] RRDYEN	This event happens when the receive buffer occupied locations are equal or above the THRSH1_REG value.
End of Frame	McBSPi.MCBSPLP_IRQS TATUS_REG[2] REOF	McBSPi.MCBSPLP_IRQENABLE_ REG[2] REOFLEN	This event happens when a complete frame was received.
Frame-sync	McBSPi.MCBSPLP_IRQS TATUS_REG[1] RFSR	McBSPi.MCBSPLP_IRQENABLE_ REG[1] RFSREN	This event happens when a new receive frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPLP_IRQS TATUS_REG[0] RSYNCERR	McBSPi.MCBSPLP_IRQENABLE_ REG[0] RSYNCERREN	This event happens when a receive frame synchronization error is detected.

Once an interrupt request is generated, the software must read the McBSPi.MCBSPLP\_IRQSTATUS\_REG register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.MCBSPLP\_IRQSTATUS\_REG register.

**Note:** All Status bits can be cleared in two ways:

- If the corresponding mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the corresponding mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the receiver/transmitter.

### 21.3.3.2.2 SIDETONE\_McBSP Interrupt Requests

The McBSP2 and McBSP3 can generate another interrupt to the MPU subsystem interrupt controller:

- **ST\_McBSPi\_IRQ:** SIDETONE interrupt request for McBSPi module (where I = 2, 3).

**Table 21-13. SIDETONE\_McBSP Interrupt Requests**

Request Name	Mapping	Destination
ST_McBSP2_IRQ	M_IRQ_4	MPU subsystem interrupt controller
ST_McBSP3_IRQ	M_IRQ_5	MPU subsystem interrupt controller

**Table 21-14. SIDETONE\_McBSP Interrupt Events**

Event Name	Status Bit	Mask Bit	Description
Over-run	McBSPi.ST_IRQSTATUS_REG[0] OVRERROR	McBSPi.ST_IRQENABLE_REG[0] OVRREROREN	This event happens when a new data to be processed arrives before the previous one has ended.

Once an interrupt request has been generated, the software must read the McBSPi.ST\_IRQSTATUS\_REG register to check what event caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.ST\_IRQSTATUS\_REG register.

- 
- Note:** The McBSPi.ST\_IRQSTATUS\_REG[0] OVRRError status bit can be cleared in two ways:
- If the McBSPi.ST\_IRQENABLE\_REG[0] OVRRErrorEN mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
  - If the McBSPi.ST\_IRQENABLE\_REG[0] OVRRErrorEN mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the SIDETONE channels.
-

## 21.4 McBSP Functional Description

This section is a functional description of the McBSP module.

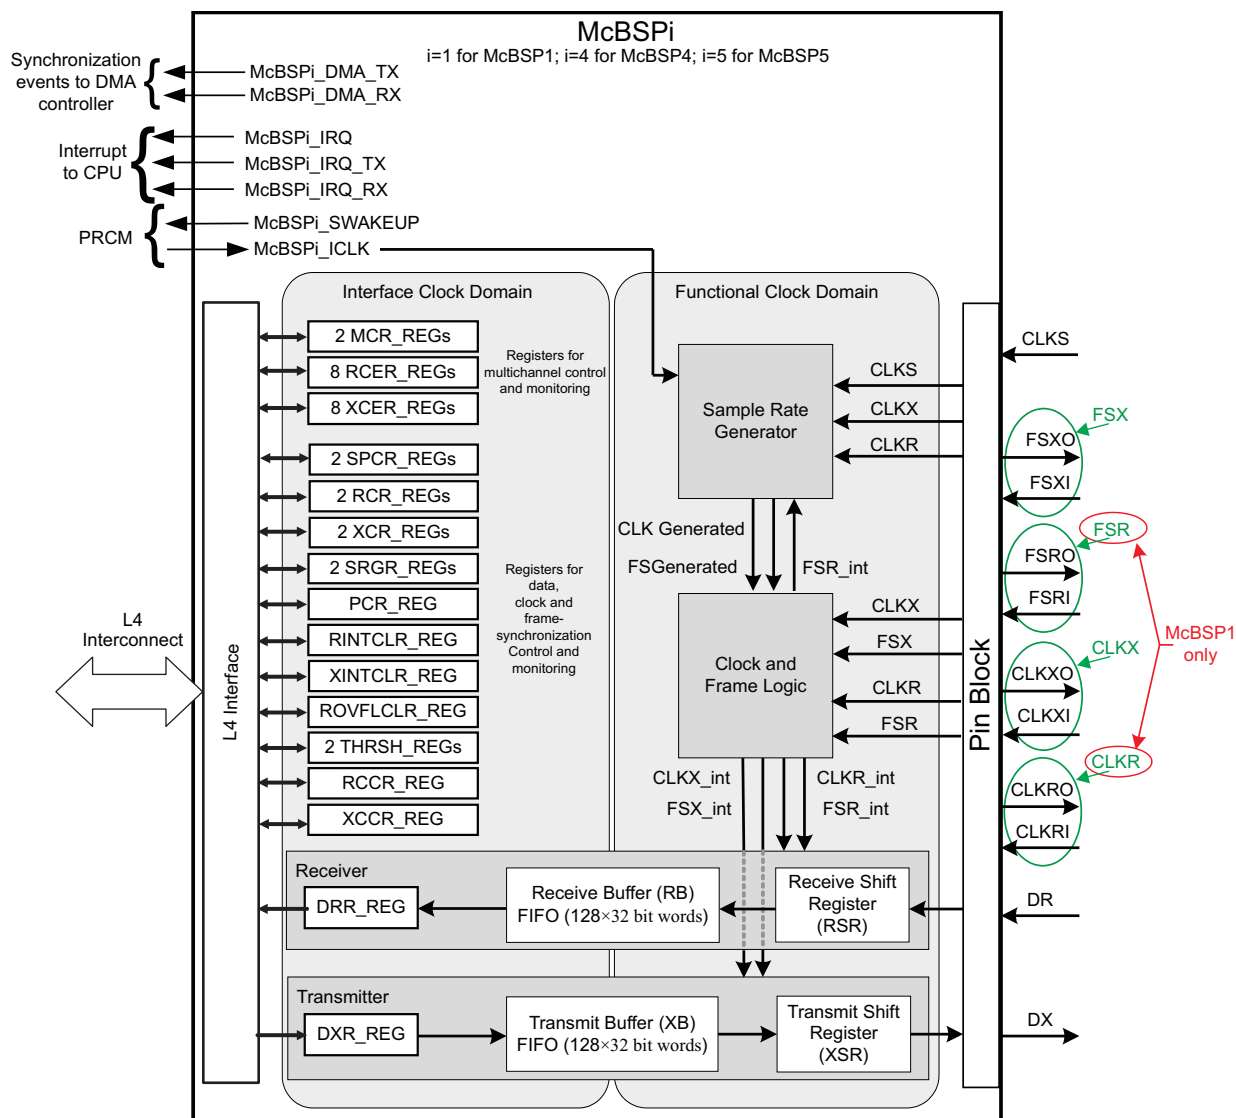

### 21.4.1 Block Diagram

Figure 21-21, Figure 21-22, and Figure 21-23 show functional block diagrams of the five instances of the McBSP modules.

These figures regroup the McBSP modules by categories:

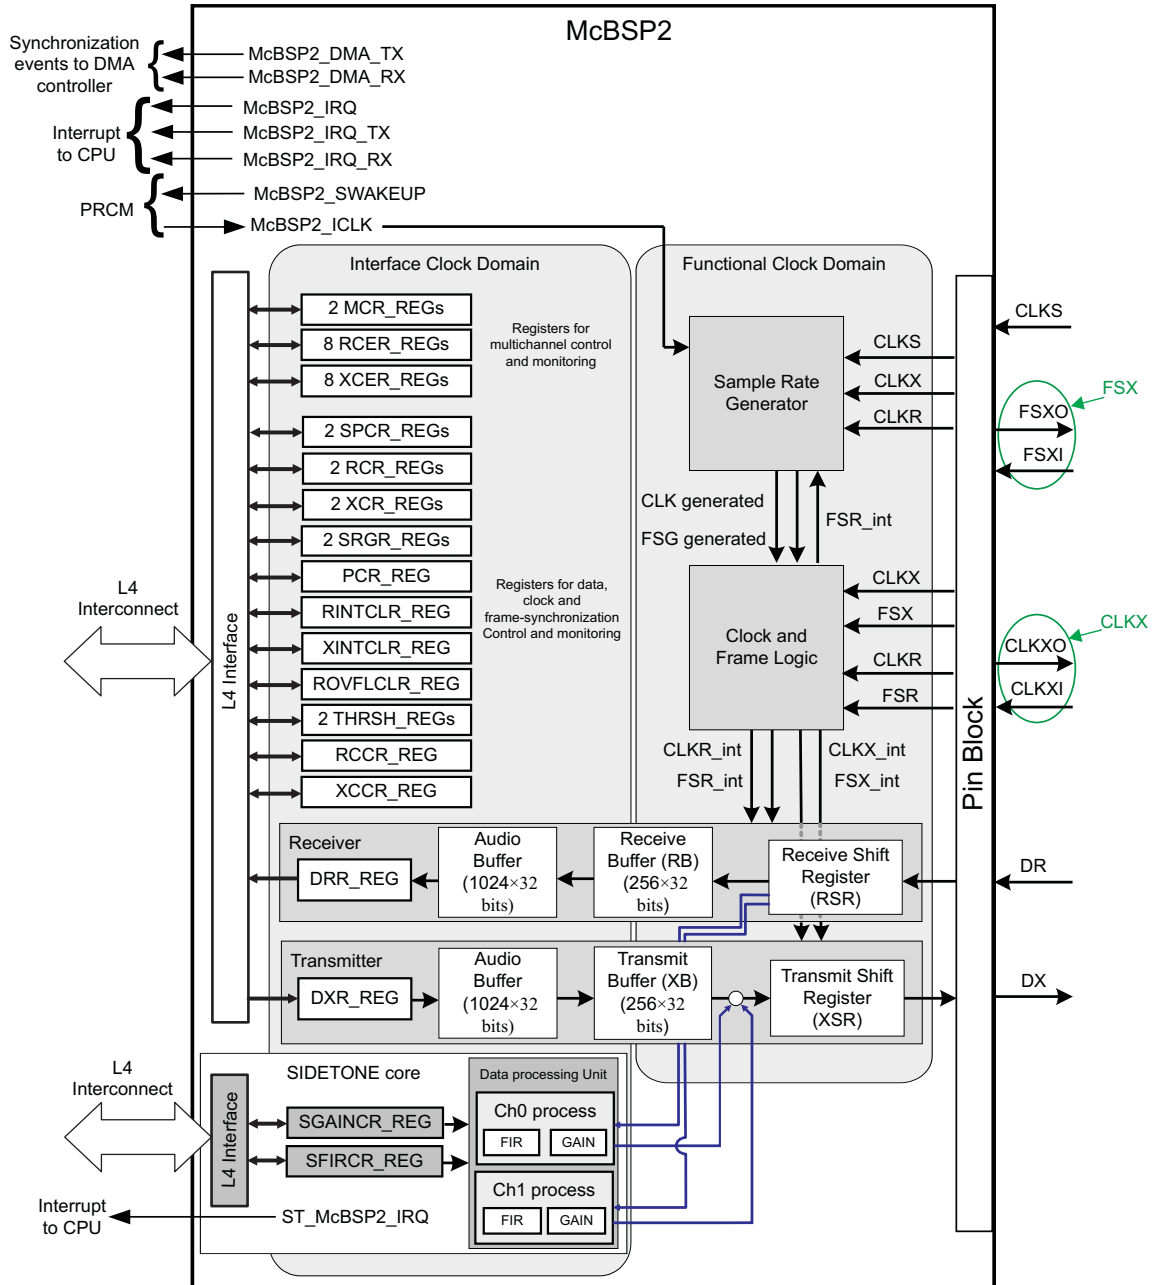

- McBSP module without audio buffer and SIDETONE core: McBSP1, McBSP4 and McBSP5
- McBSP module with audio buffer and SIDETONE core: McBSP2
- McBSP module without audio buffer, but with SIDETONE core: McBSP3

Figure 21-21. McBSP1, McBSP4 and McBSP5 Block Diagrams

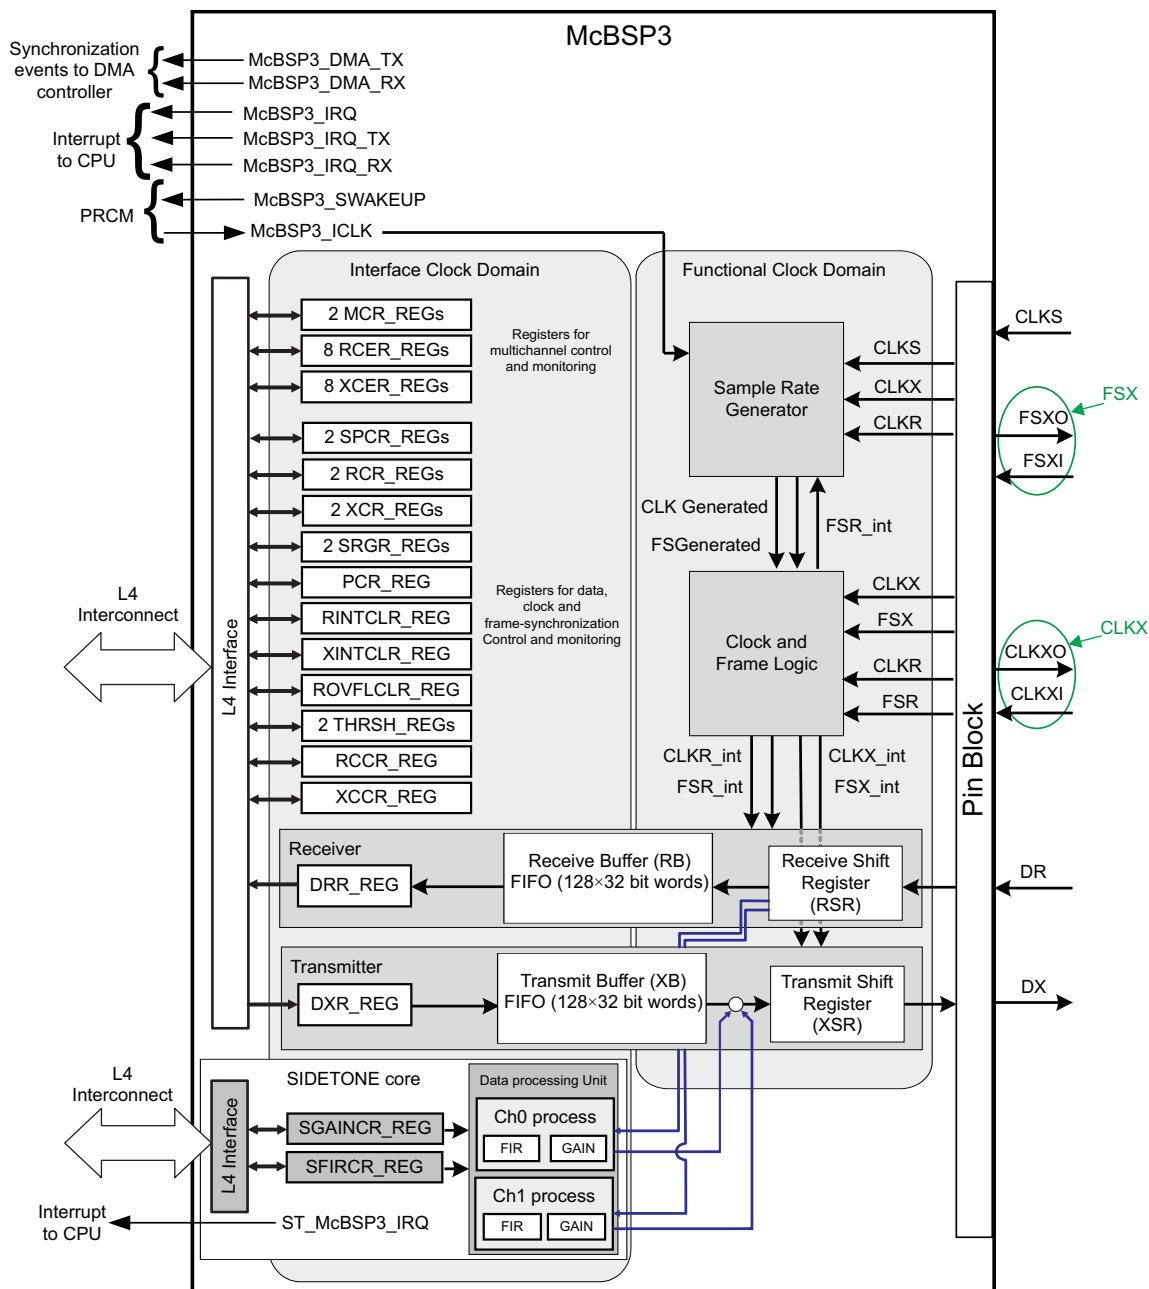

021

Figure 21-22. McBSP2 Block Diagram

022

Figure 21-23. McBSP3 Block Diagram

023

### 21.4.2 McBSP Data Transfer Process

For McBSP1, McBSP3, McBSP4, and McBSP5 modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

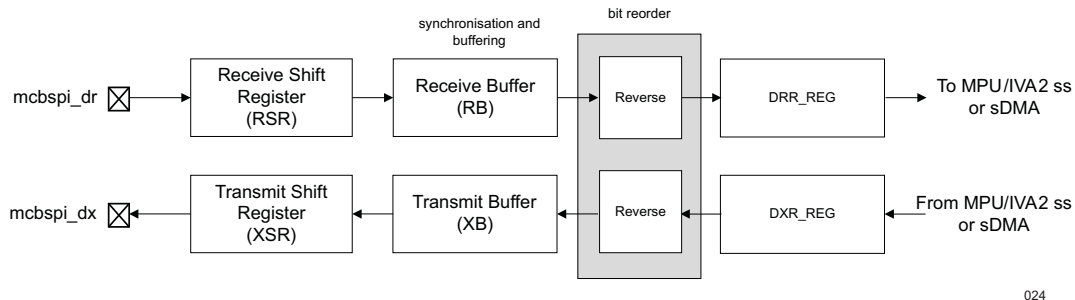

For the McBSP2 module, receive and transmit operations are quadruple-buffered (5K bytes buffers organized in 32-bit words are used). Receive and transmit buffers are separated in two memories: The same buffer as the others McBSP modules (1K bytes) and an audio buffer (4K bytes). The audio buffer is the largest one and is clocked by the interface clock, while the other buffer is used for synchronizing data to/from the audio buffer with the functional transmit/receive clock domains. Figure 21-25 shows this implementation in the McBSP2 data transfer paths.

All registers of McBSP data transfer paths are 32-bits wide. [Figure 21-24](#) and [Figure 21-25](#) illustrate the McBSP data transfer paths.

**CAUTION**

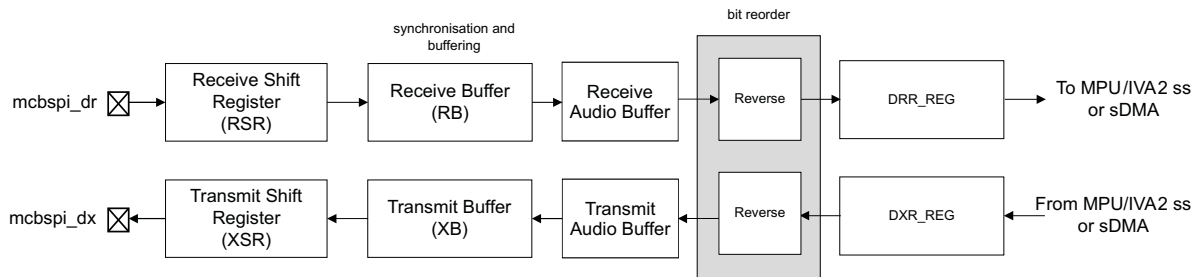

The McBSP registers (DRR\_REG and DXR\_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

**Figure 21-24. McBSP Data Transfer Paths**

024

**Figure 21-25. McBSP2 Data Transfer Paths**

068

#### 21.4.2.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

**CAUTION**

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi\_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP\_DRR\_REG).

Transmit data is written by the MPU subsystem, the IVA2.2 subsystem or the DMA controller to data transmit register (McBSPi.MCBSPLP\_DXR\_REG) using the McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi\_dx pin.

### 21.4.2.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

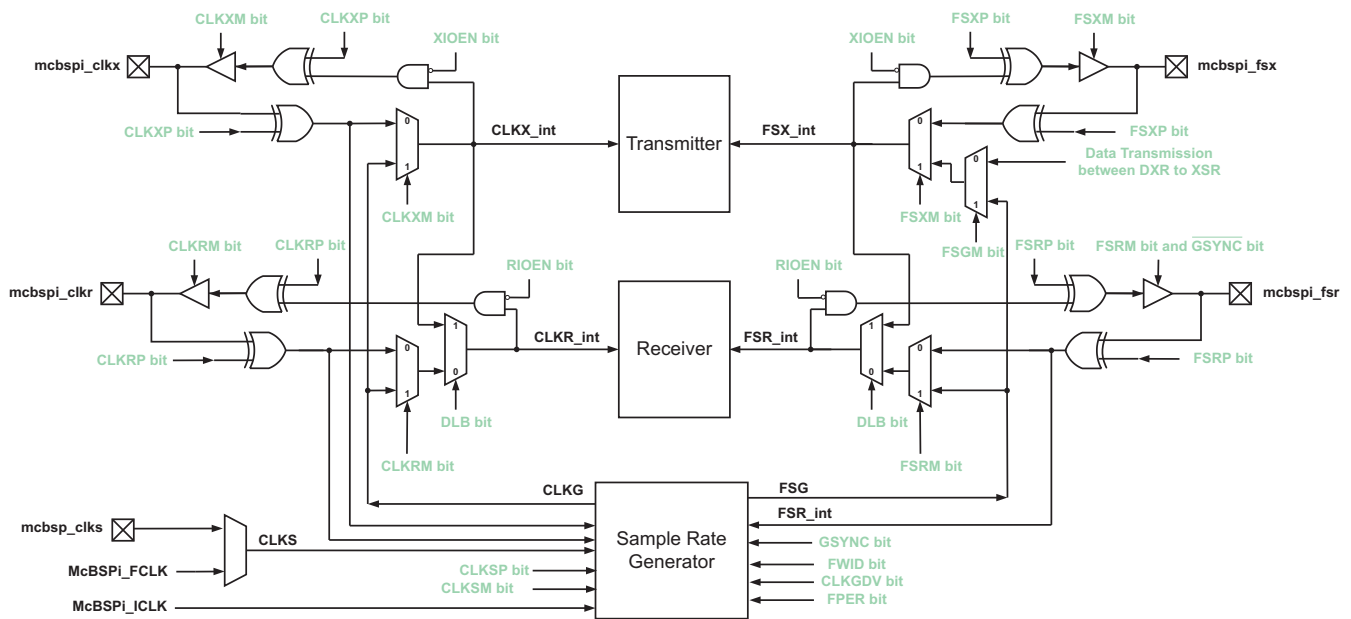

If you set `McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE=0b01`, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set `McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE=0b01`, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8 up to 32-bit data length.

### 21.4.2.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

**Figure 21-26. Conceptual Block Diagram for Clock and Frame Generation**

MCBSP\_025

#### 21.4.2.3.1 Clocking

Data is shifted one bit at a time from the `mcbspi_dr` pin to the RSRs or from the XSRs to the `mcbspi_dx` pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (`CLKR_int`) controls bit transfers from the `mcbspi_dr` pin to the RSRs. The transmit clock signal (`CLKX_int`) controls bit transfers from the XSRs to the `mcbspi_dx` pin. `CLKR_int` or `CLKX_int` signals can be derived from a pin at the boundary of the McBSP module (`mcbspi_clkr` and `mcbspi_clkx` respectively) or derived from inside the McBSP module (see Figure 21-26). The clocks source is selected by programming the `McBSPi.MCBSPLP_PCR_REG[9]` `CLKXM` bit and the `McBSPi.MCBSPLP_PCR_REG[8]` `CLKRM` bit respectively.

When the `McBSPi.MCBSPLP_PCR_REG[9]` `CLKXM` bit (transmitter clock mode) is set to:

- '0', `CLKX_int` is driven by an external clock and `mcbspi_clkx` is an input pin.
- '1', `CLKX_int` is driven by the internal sample rate generator and `mcbspi_clkx` is an output pin.

For the `McBSPi.MCBSPLP_PCR_REG[8]` `CLKRM` bit (receiver clock mode), see Table 21-15.

**Table 21-15. Receiver Clock Mode**

Value	Digital loop back mode	mcbspi_clkr pin	Description
0x0	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	input	CLKR_int is driven by an external clock
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	High-impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.
0x1	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	output	CLKR_int is driven by the internal sample rate generator
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP\_PCR\_REG register.

The McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP defines the transmit clock polarity:

- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

Figure 21-27 gives an example where the clock signal controls the timing of each bit transfer on the pin.

**Figure 21-27. Clock Signal Control of Bit Transfer Timing**

**Note:** The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV bit field.

### 21.4.2.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi\_dr or mcbspi\_dx) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field and the McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field.
- For the transmitter: the McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field and the McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field.

The difference of use is explained to [Section 21.4.2.4.1](#).

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see [Section 21.7](#))

Bits coming from the mcbspi\_dr pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the McBSPi.MCBSPLP\_DRR\_REG register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the mcbspi\_dx pin.

In the example in [Figure 21-27](#), an 8-bit word size was defined (see the transfer of the 8-bit word B).

### 21.4.2.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLEN1 field and the McBSPi.MCBSPLP\_RCR2\_REG[14:8] RFRLEN2 field.
- For the transmitter: The McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLEN1 field and the McBSPi.MCBSPLP\_XCR2\_REG[14:8] XFRLEN2 field.

The difference between these registers is explained to [Section 21.4.2.4.1](#). For the corresponding between field value and words number, see [Section 21.7](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR\_int) signal initiate frame transfers on mcbspi\_dr. Pulses on the transmit frame-sync (FSX\_int) signal initiate frame transfers on mcbspi\_dx. FSR\_int or FSX\_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi\_fsr and mcbspi\_fsx respectively) or derived from inside the McBSP module (see [Figure 21-25](#)). The frame-sync source is selected by programming the McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit and the McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit respectively.

When the McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- '0', FSX\_int is derived from an external source and mcbspi\_fsx is an input pin.
- '1', FSX\_int is determined by the McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM bit and mcbspi\_fsx is an output pin.

For the McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- '0', FSR\_int is generated by an external source and mcbspi\_fsr is an input pin
- '1', FSR\_int is generated internally by sample rate generator. The mcbspi\_fsx is an output pin except when McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit = 0x1

In the example in [Figure 21-26](#), a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.MCBSPLP\_PCR\_REG register.

The McBSPi.MCBSPLP\_PCR\_REG[3] FSXP defines the transmit frame-sync polarity:

- When set to '0', frame-sync pulse FSX is active high
- When set to '1', frame-sync pulse FSX is active low

The McBSPi.MCBSPLP\_PCR\_REG[2] FSRP defines the receive frame-sync polarity:

- When set to '0', frame-sync pulse FSR is active high
- When set to '1', frame-sync pulse FSR is active low

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

### 21.4.2.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the MPU/IVA2.2 subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see [Section 21.5](#) for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.MCBSPLP\_PCR\_REG[0] FSRM bit/McBSPi.MCBSPLP\_PCR\_REG[1] FSXM bit and McBSPi.MCBSPLP\_PCR\_REG[2] FSRP bit/McBSPi.MCBSPLP\_PCR\_REG[3] FSXP bit still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (McBSPi\_ICLK) and then sent to the MPU/IVA2.2 subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the MPU/IVA2.2 subsystem can take the serial port out of reset safely.

#### 21.4.2.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see [Section 21.4.4.3](#), or [Section 21.4.4.6](#)

#### 21.4.2.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency / (Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses)

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

#### 21.4.2.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = clock frequency / Number of bits per frame

[Figure 21-28](#) below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

**Figure 21-28. McBSP Operating at Maximum Packet Frequency**

027

If there is a 1-bit data delay as shown in [Figure 21-28](#), the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

---

**Note:** For McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX\_int). For more details, see [Section 21.5.1.6.2.2.5](#).

---

### 21.4.2.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

#### CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

#### 21.4.2.4.1 Number of Phases, Words, and Bits per Frame

Table 21-16 below shows which bit fields in the receive control registers (McBSPi.MCBSPLP\_RCR1\_REG and McBSPi.MCBSPLP\_RCR2\_REG) and in the transmit control registers (McBSPi.MCBSPLP\_XCR1\_REG and McBSPi.MCBSPLP\_XCR2\_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE => McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit
- XPHASE => McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit
- RFRLN1 => McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLN1 field
- RFRLN2 => McBSPi.MCBSPLP\_RCR2\_REG[14:8] RFRLN2 field
- XFRLN1 => McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLN1 field
- XFRLN2 => McBSPi.MCBSPLP\_XCR2\_REG[14:8] XFRLN2 field
- RWDLEN1 => McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field
- RWDLEN2 => McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field
- XWDLEN1 => McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field
- XWDLEN2 => McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field

**Table 21-16. Phases, Words and Bits per Frame Control Bit**

Operation	Number of phases	Words per frame set with	Bits per word set with
Reception	1 (RPHASE=0)	RFRLN1	RWDLEN1
Reception	2 (RPHASE=1)	RFRLN1=0x0 and RFRLN2=0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE=0)	XFRLN1	XWDLEN1
Transmission	2 (XPHASE=1)	XFRLN1=0x0 and XFRLN2=0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

#### 21.4.2.4.2 Single-Phase Frame Example

Figure 21-29 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi\_dx and mcbspi\_dr pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

**Table 21-17. Assumptions for the Single-Phase Frame Example**

Assumption	Value	Bit or Field Name
Single-phase frame	'0'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 field
8-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
word length in register2	ignored	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
1-bit data delay	01b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

**Figure 21-29. Single-Phase Frame for a McBSP Data Transfer**

#### 21.4.2.4.3 Dual-Phase Frame Example

Figure 21-30 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 21-18 shows the assumptions used to the example in Figure 21-30.

**Table 21-18. Assumptions for the Dual-Phase Frame Example**

Assumption	Value	Bit or Field name
Single-phase frame	'1'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 field
16-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
8-bit word length	0x2	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
0-bit data delay	00b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

Figure 21-30. Dual-Phase Frame for a McBSP Data Transfer

21.4.2.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see Section 21.5, Section 21.5.1.4, and Section 21.5.1.5.

Figure 21-31 and Figure 21-32 below show how reception occurs in the McBSP module. A description of the process follows the figures. Figure 21-31 shows the physical path for the data.

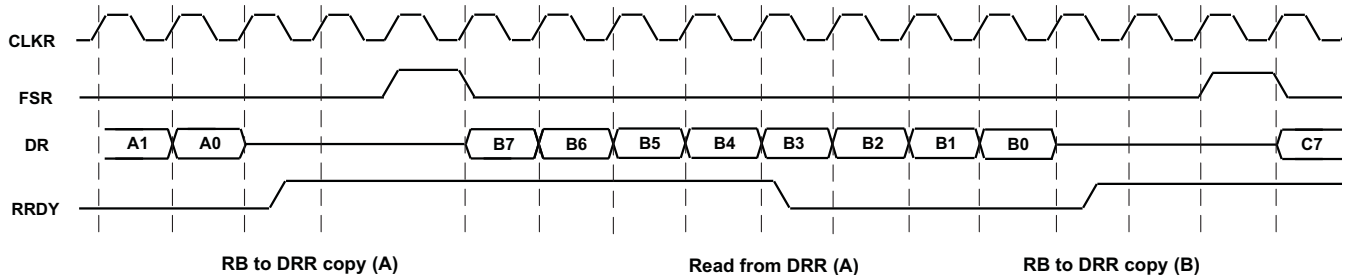

Figure 21-31. McBSP Reception Physical Data Path

030

Figure 21-32 is a timing diagram showing signal activity for one possible reception scenario.

Figure 21-32. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi\_dr pin to the MPU/IVA2.2 subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on FSR\_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi\_dr pin and shifts them into the RSR. For details on choosing a word length, see Section 21.5.1.5.2.2.2.
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP\_THRSH1\_REG[10:0] RTHRESHOLD field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit). This indicates that receive data is ready to be read by the MPU/IVA2.2 subsystem or the sDMA controller by accessing McBSPi.MCBSPLP\_DRR\_REG register.

The data copied from RB to McBSPi.MCBSPLP\_DRR\_REG is justified and bit filled according to the

McBSPi.MCBSPLP\_SPCR1\_REG[14:13] RJUST field.

- The MPU/IVA2.2 subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit is cleared.

#### 21.4.2.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see [Section 21.5](#), and [Section 21.5.1.6](#).

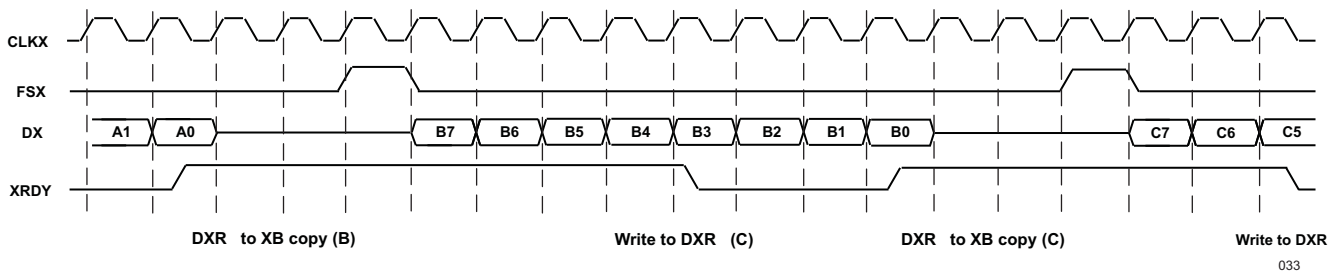

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. [Figure 21-33](#) shows the physical path for the data.

**Figure 21-33. McBSP Transmission Physical Data Path**

[Figure 21-34](#) is a timing diagram showing signal activity for one possible transmission scenario.

**Figure 21-34. McBSP Transmission Signal Activity**

XRDY: Status of transmitter ready bit (high is 1)

- The MPU/IVA2.2 subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP\_DXR\_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see [Section 21.5.1.6.2.2.2](#).
- When new data arrives in McBSPi.MCBSPLP\_DXR\_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPLP\_THRSH2\_REG[10:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/IVA2.2 subsystem or the sDMA controller.
- The McBSP module waits for a transmit frame-synchronization pulse on FSX\_int.
- When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY field.  
In the preceding timing diagram, a 1-bit data delay is selected.
- The McBSP module shifts data bits from the XSR to the mcbspi\_dx pin.

#### 21.4.2.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE/McBSPi.MCBSPLP\_RCCR\_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPLP\_IRQSTATUS\_REG[8] XFSX / McBSPi.MCBSPLP\_IRQSTATUS\_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE/McBSPi.MCBSPLP\_RCCR\_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

**Note:** It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP\_XBUFFSTAT\_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP\_RBUFFSTAT\_REG[7:0] RBUFFSTAT field indicating the occupied/available buffer locations), since this register is an interface clock (McBSPi\_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

### 21.4.2.8 McBSP Data Transfer Mode

**Note:** For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP bit=0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit=0x0). There are the reset values.

In timing diagrams below, a 1-bit data delay is selected (McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY field=0x01 and McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY field=0x01), because data often follows a 1-cycle active frame-synchronisation.

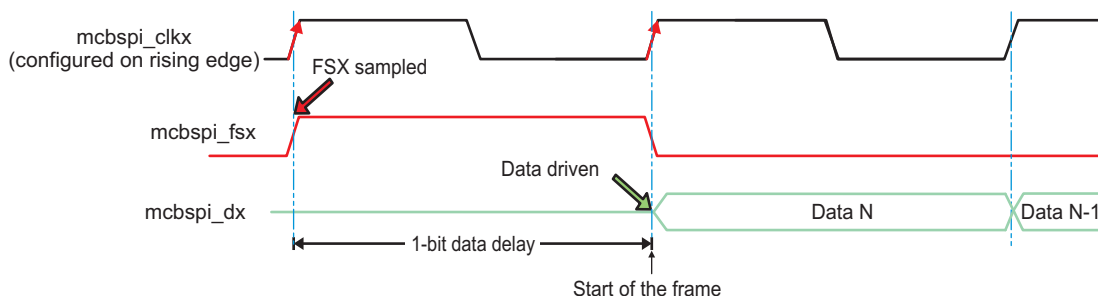

McBSP modules can support 2 edge selection modes for transmit and receive data transfer at the system level:

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). Note that a new data is generated only every clock period, which permits to guarantee the required hold time.

#### 21.4.2.8.1 Transmit Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See [Figure 21-35](#).

Figure 21-35. Transmit Full Cycle Timing Diagram

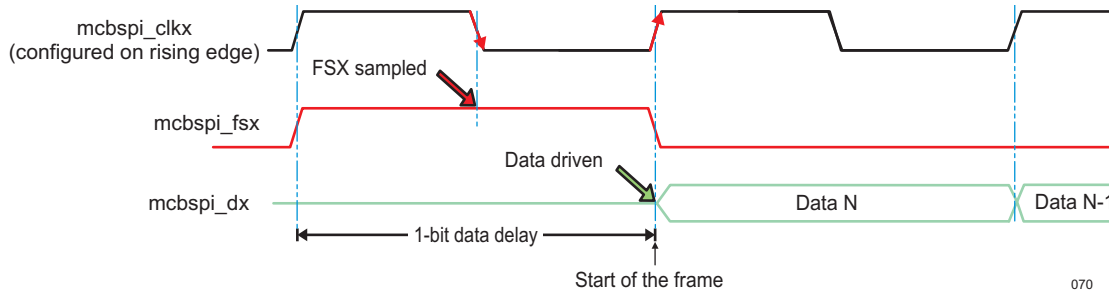

069

### 21.4.2.8.2 Transmit Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 21-36.

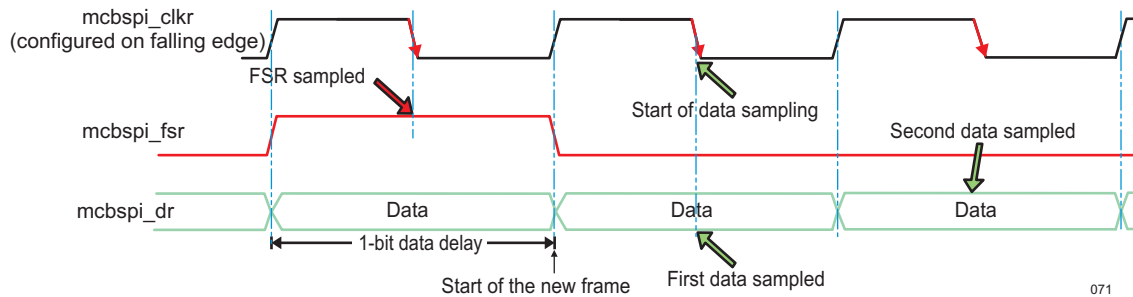

**Figure 21-36. Transmit Half Cycle Timing Diagram**

### 21.4.2.8.3 Receive Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 21-37.

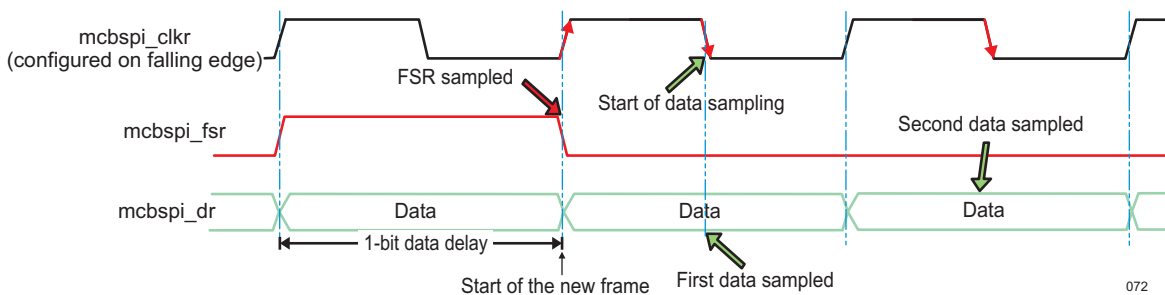

**Figure 21-37. Receive Full Cycle Timing Diagram**

### 21.4.2.8.4 Receive Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 21-38.

**Figure 21-38. Receive Half Cycle Timing Diagram**

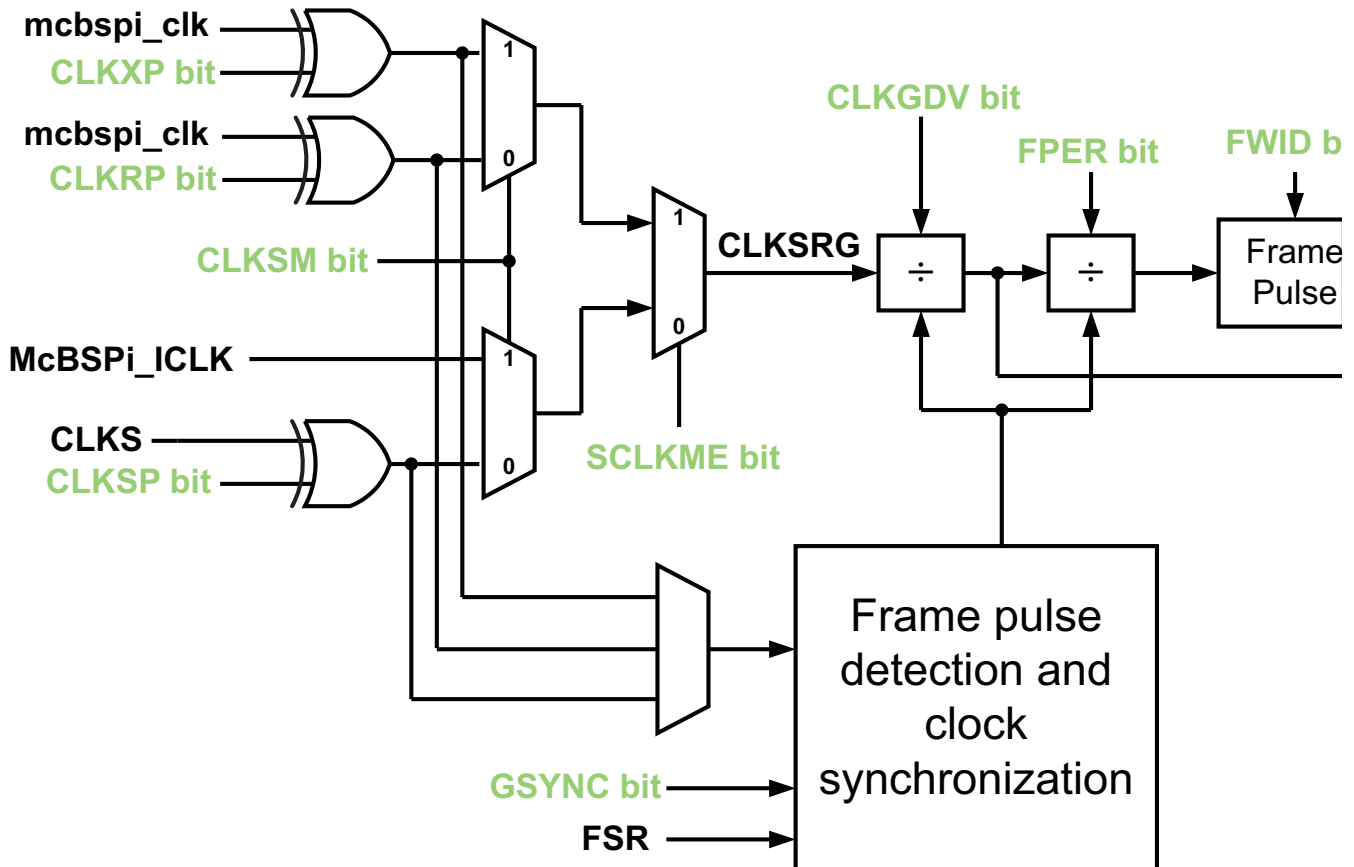

### 21.4.3 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi\_dr) and/or the data transmit pin (mcbspi\_dx). FSG can be used to initiate frame transfers on mcbspi\_dr pin and/or mcbspi\_dx pin. Figure 21-39 is a conceptual block diagram of the SRG.

Figure 21-39. Conceptual Block Diagram of the Sample Rate Generator

The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by either the interface clock (McBSPi\_ICLK), or the functional clock (CLKS input), or by an external pin (mcbspi\_clkx, or mcbspi\_clkr). The source is selected with the McBSPi.MCBSPLP\_PCR\_REG[7] SCLKME bit and the McBSPi.MCBSPLP\_SRGR2\_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP\_SRGR2\_REG[14] CLKSP bit, McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP bit, or McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit).

The SRG has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field to control the width of each frame-synchronization pulse

---

**Note:** The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

---

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbspi\_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM / McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see [Figure 21-26](#)).

For details on getting the sample rate generator ready for operation, see [Section 21.5](#).

#### 21.4.3.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM and McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP and McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in [Table 21-19](#). The ALB mode is selected with the McBSPi.MCBSPLP\_SPCR1\_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the System Control Module (more details, refer [Section 21.3.1](#))

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit =1).

**Table 21-19. Effects of DLB and ALB Bits on Clock Modes**

	Mode Bit Settings	Effect
CLKRM=1	DLB=0 and ALB = 0 (Digital and analog loop back mode disabled)	mcbasp1_clkr is an output pin driven by the SRG output clock (CLKG).
	DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbasp1_clkr is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by CLKX input signal provided by mcbspi_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input signal provided by mcbspi_fsx pin. The receive data is driven by the DX input loop-back pin (mcbspi_dx).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
CLKXM= 1	DLB=0 & ALB = 0 (Digital & analog loop back mode disabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 & ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
	SCM.CONTROL_DEVCONF0[3] MCBSP1_CLKR bit =1 (synchronous setting and DLB = 0 & ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

### 21.4.3.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbspi\_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.MCBSPLP\_PCR\_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbspi\_fsx pin.
- MCBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

---

**Note:** When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER and McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

---

In either case, the SRG must be enabled (McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.MCBSPLP\_SPCR2\_REG[7] FRST bit=0).

#### 21.4.3.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

#### 21.4.3.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit =1, FSG pulses in response to an inactive-to-active transition on the mcbspi\_fsr pin. Thus, an external device controls the frame-synchronization period.
- Otherwise, the software program the McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field, and the resulting frame-synchronization period is (FPER+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

#### 21.4.3.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit and the mcbspi\_fsr pin can be used to configure the timing of FSG pulses.

McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC=1, an inactive-to-active transition on the mcbspi\_fsr pin triggers a resynchronization of CLKG and generation of FSG.

#### 21.4.3.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (McBSPi\_ICLK), or the CLKS signal (PRCM functional clock or mcbbsp\_clks), or a signal at the mcbspi\_clkr, or mcbspi\_clkx pin. When an external clock (mcbbsp\_clks, or mcbspi\_clkr, or mcbspi\_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit and the mcbspi\_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit=1:

- An inactive-to-active transition on the mcbspi\_fsr pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the mcbspi\_fsr pin.

If the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field.

### 21.4.3.3.1 Operating the Transmitter Synchronously with the Receiver

When the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit = 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM = 1 and McBSPi.MCBSPLP\_PCR\_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting McBSPi.MCBSPLP\_PCR\_REG[11] FSXM=0 and connecting FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit and McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

### 21.4.3.3.2 Synchronization Examples

Figure 21-40 and Figure 21-41 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbspi\_fsr pin.

Each figure shows what happens to CLKG signal when the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. Figure 21-41 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV field).

**Figure 21-40. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)**

035

**Figure 21-41. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)**

## 21.4.4 McBSP Exception/Error Conditions

### 21.4.4.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT bit is set to 1, and legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL bit is set to 1)  
This occurs when RB is full and RSR are full with another new word shifted in from mcbspi\_dr. Therefore, McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT (McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi\_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi\_dr and McBSPi.MCBSPLP\_DRR\_REG register is not read. For more details about overrun in the receiver, see [Section 21.4.4.2](#).
- Unexpected receive frame-synchronization pulse (McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR bit is set to 1, and legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit is set to 1).  
This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see [Section 21.4.4.3, Unexpected Receive Frame-Sync Pulse](#).
- Receiver underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[4] RUNDLSTAT bit is set to '1')  
This occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see [Section 21.4.4.4](#).
- Transmitter underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY bit is set to '0')  
If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.MCBSPLP\_DXR\_REG register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see [Section 21.4.4.5](#).
- Unexpected transmit frame-synchronization pulse (McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR bit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit is set to '1')  
This occurs during transmission when an unexpected frame-synchronization pulse arrives. An

unexpected pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit. For more details see Section 21.4.4.6.

- Transmitter overflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[12] XOVFLSTAT bit is set to '1')  
This occurs when sDMA controller or MPU/IVA2.2 subsystem writes data to a full XB. For more details about underflow in the receiver, see Section 21.4.4.7.

### 21.4.4.2 Overrun in the Receiver

When McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT bit set to '1', and McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP\_DRR\_REG is not read even if the McBSPi.MCBSPLP\_IRQSTATUS\_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on mcbspi\_dr is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL bit and allows subsequent transfers to be read properly:

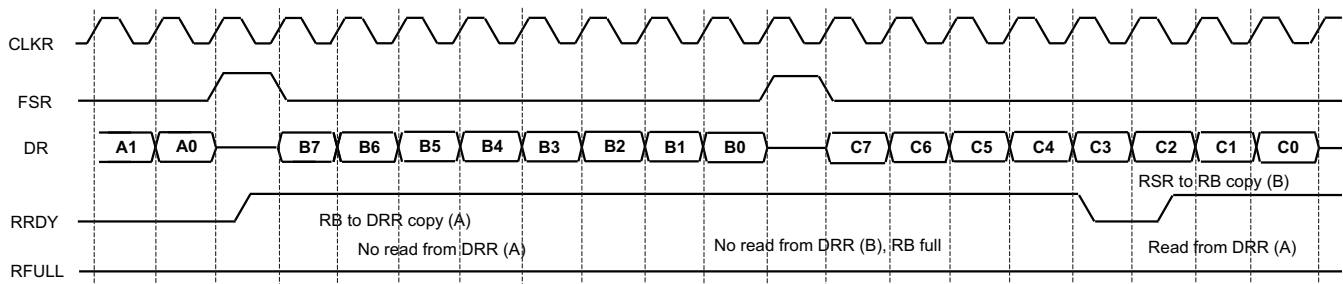

- The MPU/IVA2.2 subsystems or sDMA controller reads McBSPi.MCBSPLP\_DRR\_REG.
- The receiver is reset individually (McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register setting, this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

Figure 21-42 shows the receive overrun condition.

Figure 21-42. Overrun in the McBSP Receiver

037

### 21.4.4.3 Unexpected Receive Frame-sync Pulse

#### 21.4.4.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR (and the legacy McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit).

According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

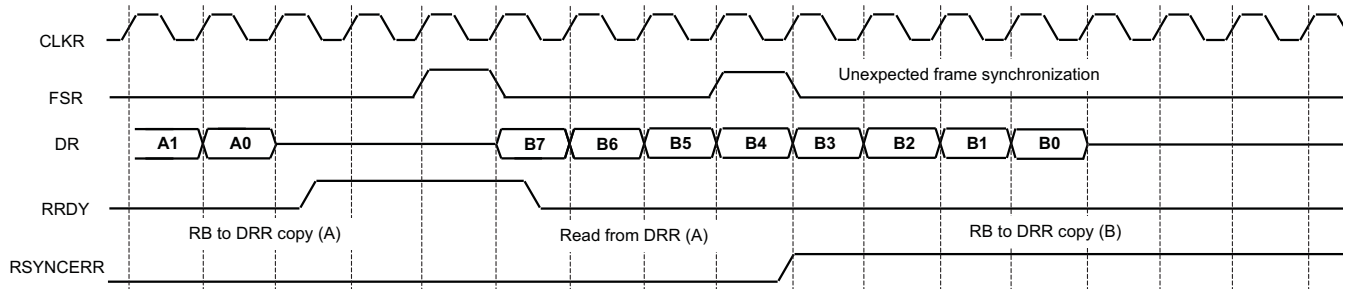

Using the legacy mode, McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the McBSPi.MCBSPLP\_SPCR1\_REG[5:4] RINTM field. When RINTM = 0b11, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/IVA2.2 subsystems each time that RSYNCERR is set.

#### 21.4.4.3.2 Example of an Unexpected Receive Frame-sync Pulse

Figure 21-43 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

**Note:** The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

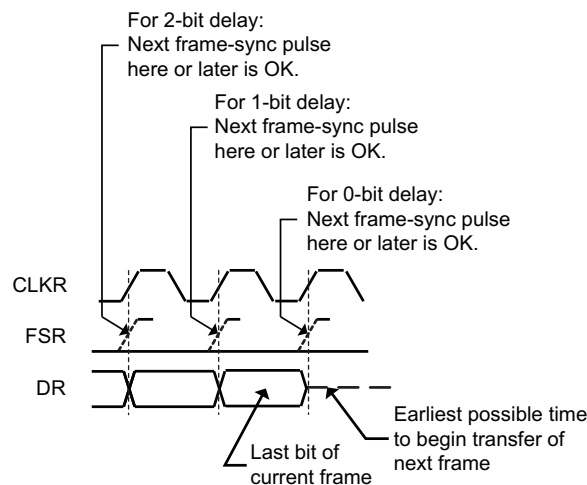

**Figure 21-43. Unexpected Frame-sync Pulse During a McBSP Reception**

#### 21.4.4.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY field. For each possible data delay, Figure 21-44 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

**Figure 21-44. Proper Positioning of Receive Frame-sync Pulses**

039

#### 21.4.4.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[4] RUNDFLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty RB this happens only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

#### 21.4.4.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDFLSTAT bit. Also the legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY bit is cleared. Either of the following events activates XEMPTY bit (XEMPTY = 0):

- McBSPi.MCBSPLP\_DXR\_REG has not been loaded and XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi\_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST=0, or by an global reset) and is then restarted.

XEMPTY bit is deactivated (XEMPTY=1) when a new word in McBSPi.MCBSPLP\_DXR\_REG is transferred to Transmit Buffer (XB). If McBSPi.MCBSPLP\_PCR\_REG[11] FSXM=1 and McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM=0, the transmit frame-sync signal (FSX) is generated when Transmit Buffer (XB) is not empty. When McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM=0, McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER and McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID are used to determine the frame-synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on mcbspi\_dx.

When the transmitter is taken out of reset (McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST=1), it is in a transmitter ready state (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit =1) and transmitter empty (McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY=0) state. If McBSPi.MCBSPLP\_DXR\_REG is loaded by the MPU/IVA2.2 subsystem or the sDMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before McBSPi.MCBSPLP\_DXR\_REG is loaded, zeros are output on mcbspi\_dx.

The McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

#### 21.4.4.6 Unexpected Transmit Frame-sync Pulse

##### 21.4.4.6.1 Possible Responses to Transmit Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit).

According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings, this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

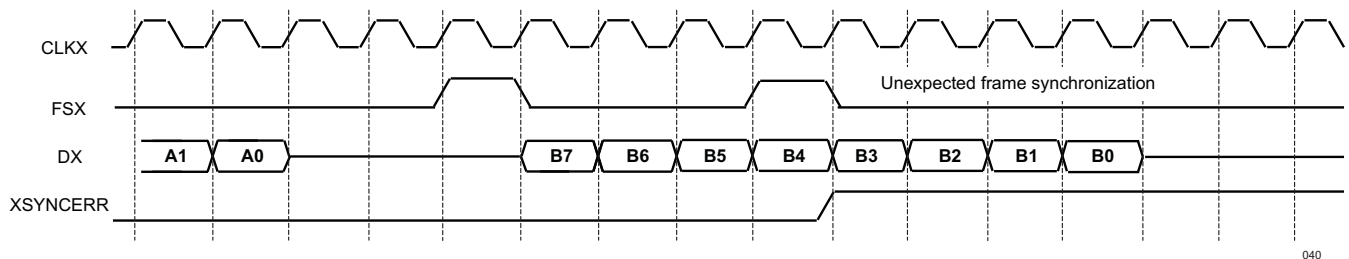

Using the legacy mode, McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.MCBSPLP\_SPCR2\_REG[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/IVA2.2 subsystem each time that XSYNCERR is set.

#### 21.4.4.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 21-45 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

**Note:** The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

**Figure 21-45. Unexpected Frame-sync Pulse During a McBSP Transmission**

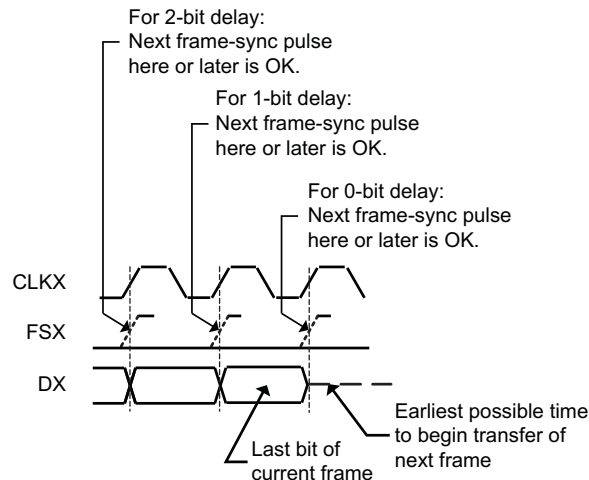

040

#### 21.4.4.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY field. For each possible data delay, Figure 21-46 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

**Figure 21-46. Proper Positioning of Transmit Frame-sync Pulses**

041

#### 21.4.4.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[12] XOVLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem write data to a full XB (this may happen only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

#### 21.4.5 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST and transmit McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP\_RCCR\_REG[3] RDMAEN, McBSPi.MCBSPLP\_XCCR\_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through McBSPi.MCBSPLP\_THRSH1\_REG and McBSPi.MCBSPLP\_THRSH2\_REG registers as follows:

- (THRSH1\_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1\_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1\_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2\_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2\_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2\_REG + 1) number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

---

**Note:** The MPU/IVA2.2 subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/IVA2.2 subsystem) and the common interrupt line (McBSPi\_IRQ) can be used. The McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit for receive and McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP\_RBUFFSTAT\_REG register and transmit buffer status McBSPi.MCBSPLP\_XBUFFSTAT\_REG register, the MPU/IVA2.2 subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/IVA2.2 subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

---

#### 21.4.6 Multichannel Selection Modes

##### 21.4.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each:

- Block 0: Channels 0–15
- Block 1: Channels 16–31
- Block 2: Channels 32–47

- Block 3: Channels 48–63
- Block 4: Channels 64–79
- Block 5: Channels 80–95
- Block 6: Channels 96–111
- Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in [Section 21.4.6.6](#), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode [Section 21.4.6.4](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

#### 21.4.6.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode [Section 21.4.6.5](#), and three transmit multichannel selection modes [Section 21.4.6.7](#).

#### 21.4.6.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit and McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit = 0). Each frame represents a TDM data stream.
- Set a frame length (in McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFLEN1 field and in McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFLEN1 = 39). If XFLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

#### 21.4.6.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME = 1 for reception, McBSPi.MCBSPLP\_MCR2\_REG[9] XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.MCBSPLP\_MCR1\_REG[6:5] RPBLK and McBSPi.MCBSPLP\_MCR2\_REG[6:5] XPBLK, and McBSPi.MCBSPLP\_MCR1\_REG[8:7] RPBBLK and McBSPi.MCBSPLP\_MCR2\_REG[8:7] XPBBLK bit fields are ignored, and the 16 channel blocks are assigned to the partitions as shown in [Table 21-20](#) through [Table 21-21](#). These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

**Table 21-20. Eight Partitions – Receive Channel Assignment and Control**

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi.MCBSPLP_RCERA_REG
B	Block 1: Channels 16 through 31	McBSPi.MCBSPLP_RCERB_REG
C	Block 2: Channels 32 through 47	McBSPi.MCBSPLP_RCERC_REG
D	Block 3: Channels 48 through 63	McBSPi.MCBSPLP_RCERD_REG
E	Block 4: Channels 64 through 79	McBSPi.MCBSPLP_RCERE_REG
F	Block 5: Channels 80 through 95	McBSPi.MCBSPLP_RCERF_REG
G	Block 6: Channels 96 through 111	McBSPi.MCBSPLP_RCERG_REG
H	Block 7: Channels 112 through 127	McBSPi.MCBSPLP_RCERH_REG

**Table 21-21. Eight Partitions – Transmit Channel Assignment and Control**

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi.MCBSPLP_XCERA_REG
B	Block 1: Channels 16 through 31	McBSPi.MCBSPLP_XCERB_REG
C	Block 2: Channels 32 through 47	McBSPi.MCBSPLP_XCERC_REG
D	Block 3: Channels 48 through 63	McBSPi.MCBSPLP_XCERD_REG
E	Block 4: Channels 64 through 79	McBSPi.MCBSPLP_XCERE_REG
F	Block 5: Channels 80 through 95	McBSPi.MCBSPLP_XCERF_REG
G	Block 6: Channels 96 through 111	McBSPi.MCBSPLP_XCERG_REG
H	Block 7: Channels 112 through 127	McBSPi.MCBSPLP_XCERH_REG

Figure 21-47 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

**Figure 21-47. McBSP Data Transfer in 8-Partition Mode**

#### 21.4.6.5 Receive Multichannel Selection Mode

The McBSPi.MCBSPLP\_MCR1\_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:
  - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP\_RCERA\_REG to McBSPi.MCBSPLP\_RCERH\_REG). The channels are assigned to the McBSPi.MCBSPLP\_RCERA\_REG to McBSPi.MCBSPLP\_RCERH\_REG registers depends on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME bit.
  - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP\_SPCR1\_REG[5:4] RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi\_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi\_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi\_dr pin in channel 39

#### 21.4.6.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME = 0 for reception, McBSPi.MCBSPLP\_MCR2\_REG[9] XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP\_MCR1\_REG[6:5] RPABLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (McBSPi.MCBSPLP\_RCERA\_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP\_MCR1\_REG[8:7] RPBBLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP\_RCERB\_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP\_MCR2\_REG[6:5] XPABLK fields. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP\_XCERA\_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP\_MCR1\_REG[8:7] XPBBLK field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP\_XCERB\_REG).

Figure 21-48 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

### 21.4.6.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in [Table 21-22](#).

**Table 21-22. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field**

XMCM	Transmit Multichannel Selection Mode
0b00	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCM bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCM bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCM bit determines whether 32 channels or 128 channels are selectable in McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi\_dx pin in channel 0
2. Places the mcbspi\_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi\_dx pin in channel 15
4. Places the mcbspi\_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi\_dx pin in channel 39

#### 21.4.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in [Table 21-23](#) explain the channel control options:

**Table 21-23. McBSP Channel Control Options**

<b>Enabled channel</b>	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through XB.
<b>Masked channel</b>	A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
<b>Disabled channel</b>	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM=00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
<b>Unmasked channel</b>	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

### 21.4.6.7.2 Activity on McBSP Pins for Different Values of XMCM

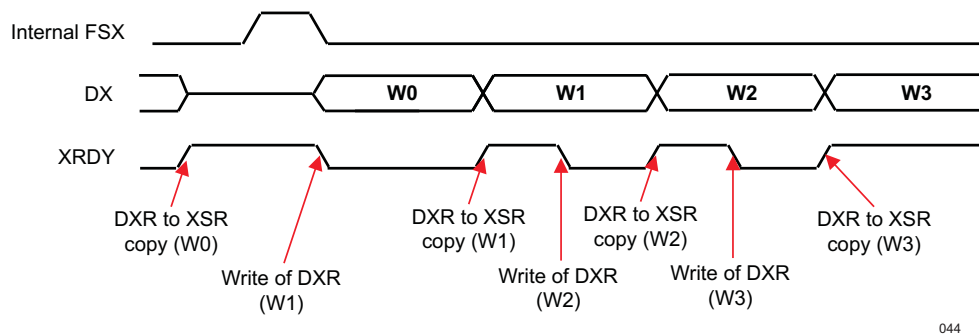

Figure 21-49 shows the activity on the McBSP pins for the various McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single-phase frame (required for multichannel selection modes)
- XFRLLEN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2-partition mode (only partitions A and B used)

In the case where McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLLEN1, and XWDLEN1, respectively.

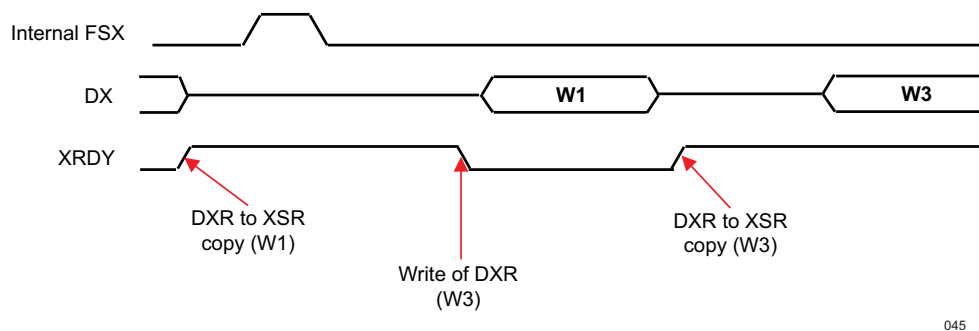

In Figure 21-49, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

**Figure 21-49. Activity on McBSP Pins When XMCM=0b00**

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi\_dx.

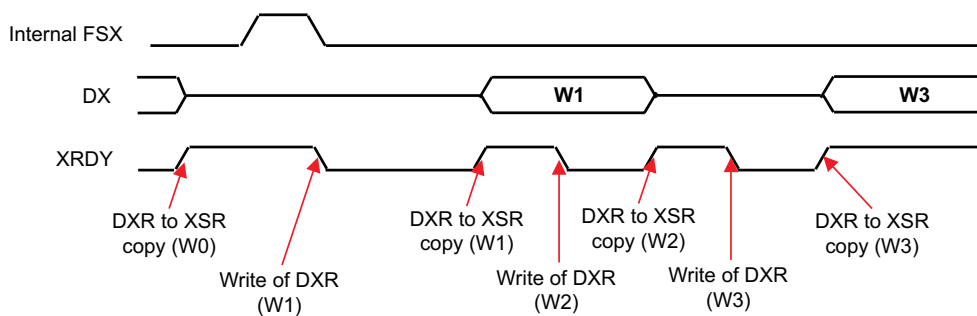

**Figure 21-50. Activity on McBSP Pins When XMCM=0b01**

In Figure 21-50 if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi\_dx.

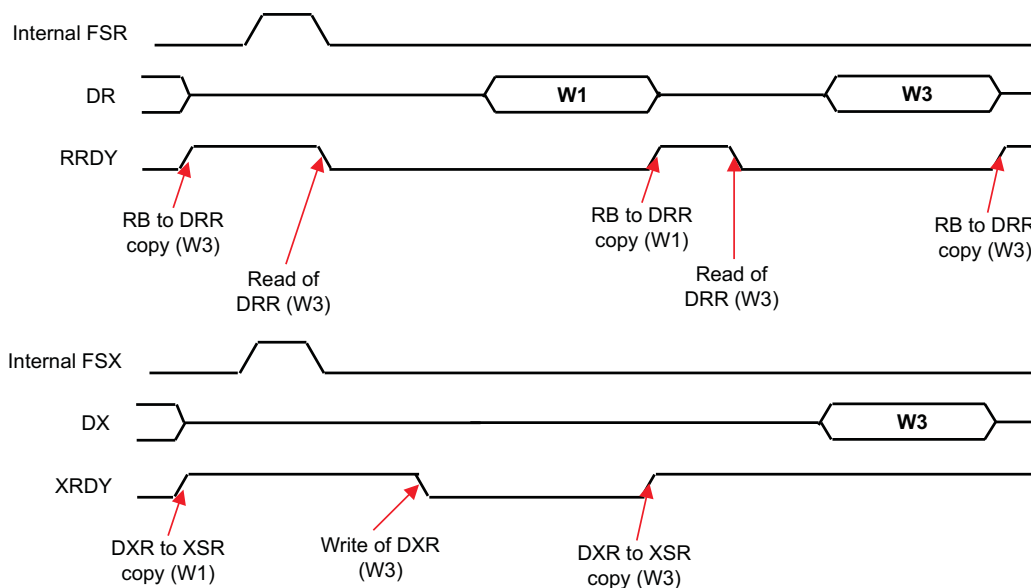

**Figure 21-51. Activity on McBSP Pins When XMCM=0b10**

046

In [Figure 21-51](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi\_dx.

**Figure 21-52. Activity on McBSP Pins When XMCM=0b11**

047

In [Figure 21-52](#) if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi\_dx.

## 21.4.7 SIDETONE Mode (ALP)

### 21.4.7.1 Introduction

In multimedia-rich mobile communication devices, loopback signals from audio inputs to audio outputs are renamed. A traditional example is the telephone SIDETONE (that is, the telephone user expects to also hear his own voice in the earpiece).

Some of the features using the loopback have strict delay requirements.

It is required that two of the audio input channels be looped back, filtered, and mixed to the corresponding two audio output channels. The SIDETONE mode filters and applies gain to each sample received.

### 21.4.7.2 SIDETONE Interface

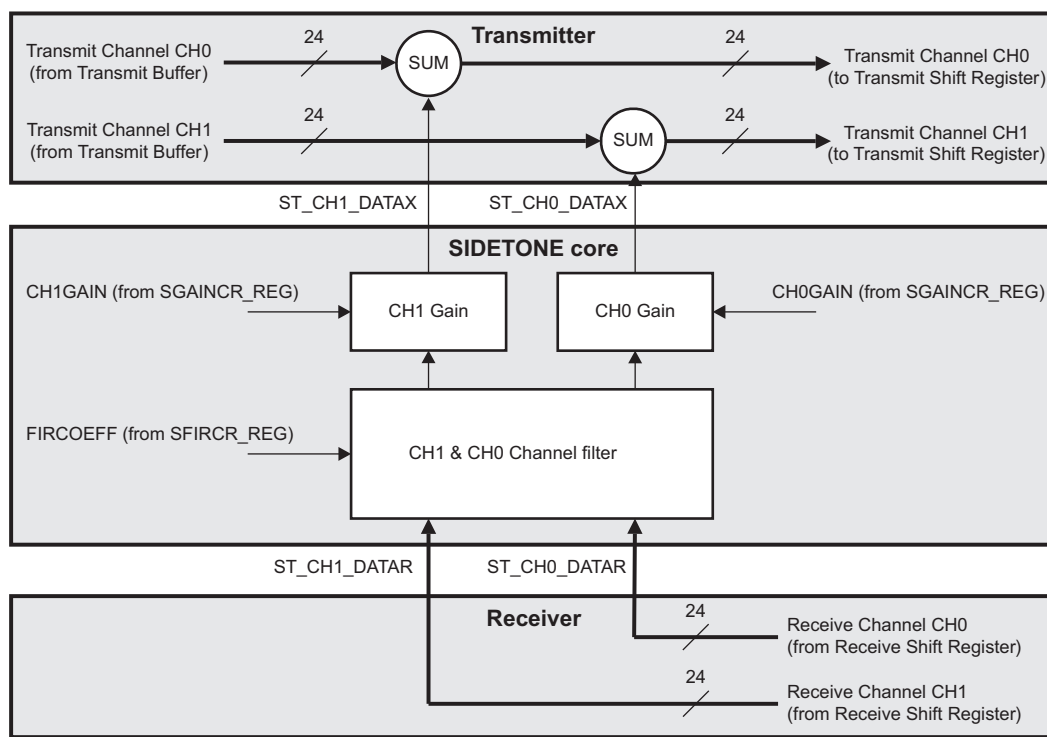

The data from digital microphone, two (out of four) channels, can be configured to be input in the external SIDETONE core. After filtering, the data from digital microphone data is mixed and sent out to the speaker output channels using two (out of eight) configured output channels (separate configuration bits are used). The McBSP module synchronizes the incoming data (filtered by the external SIDETONE core). The transmit and receive part of the McBSP module are not required to operate on the same functional frequency.

The SIDETONE interface offers the following features:

- Send out two 24-bit data channels for the configured SIDETONE received channels (channels can be the same)
- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 21-53 shows the SIDETONE external module data path:

**Figure 21-53. SIDETONE Data Path**

MCBSP\_048

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel and SIDETONE mode:

- Select a single-phase frame (McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit and McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.MCBSPLP\_MCR1\_REG[0] RMCM=1 to select multichannel mode enable.
- Set a frame length (in McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLEN1 bit field and in McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 bit field and in

McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see note).

- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.MCBSPLP\_SSELCR\_REG[1:0] ICH0ASSIGN/McBSPi.MCBSPLP\_SSELCR\_REG[6:4] OCH0ASSIGN, McBSPi.MCBSPLP\_SSELCR\_REG[3:2] ICH1ASSIGN/McBSPi.MCBSPLP\_SSELCR\_REG[9:7] OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.MCBSPLP\_SSELCR\_REG[10] SIDETONEEN bit to 1.

**Note:** Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 21-54 describes the data exchange protocol between McBSP module and SIDETONE core:

**Figure 21-54. McBSP to SIDETONE Data Exchange**

Figure 21-55 describes the data exchange protocol between SIDETONE core and McBSP module:

**Figure 21-55. SIDETONE to McBSP Data Exchange**

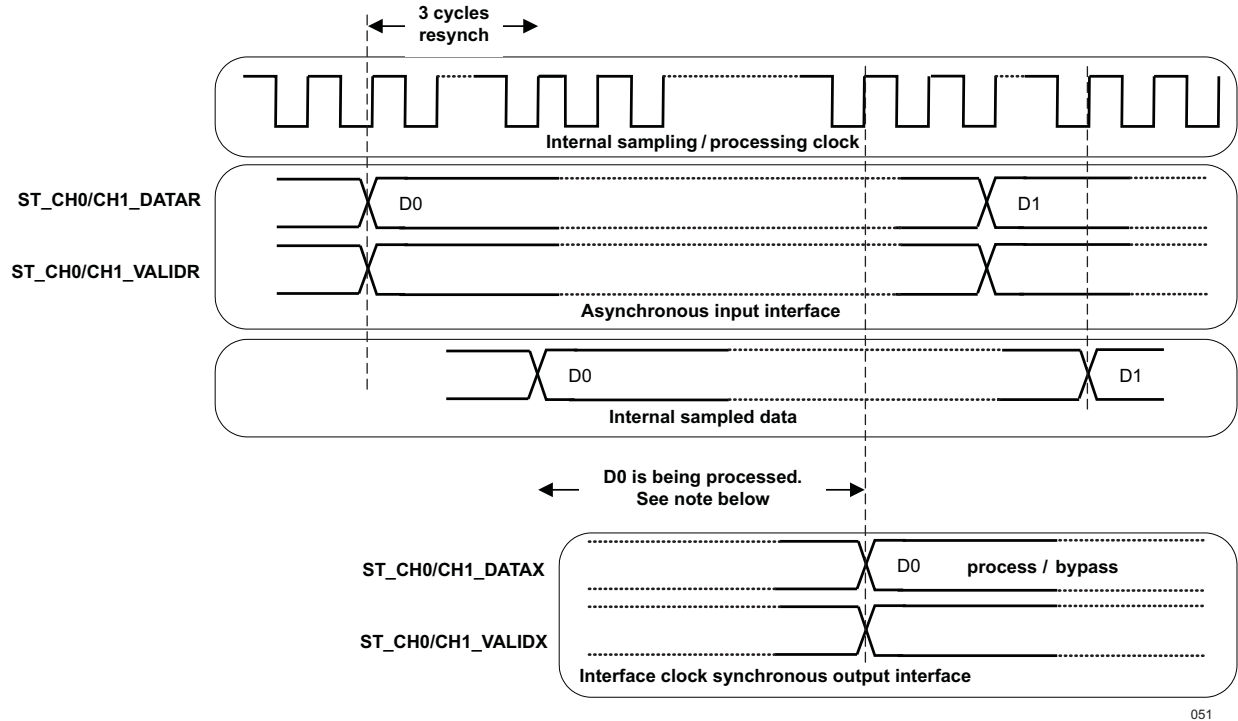

**Note:** To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPLP\_SSELCR\_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPLP\_SSELCR\_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

### 21.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.ST\_SSELCR\_REG[0] SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

Figure 21-56 below describes how the data is sampled and output through the dedicated data interfaces.

**Figure 21-56. SIDETONE Processed Data Interfaces**

051

**Note:** The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The ST\_CH0\_VALIDR and ST\_CH1\_VALIDR are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from ST\_CH0\_DATAR / ST\_CH1\_DATAR.

The ST\_CH0\_VALIDX and ST\_CH1\_VALIDX are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus ST\_CH0\_DATAX / ST\_CH1\_DATAX.

#### 21.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

##### 21.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.

$$|C0| + |C1| + \dots + |C127| < 1$$

### CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

#### 21.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.ST\_SGAINCR\_REG. The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

#### 21.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.ST\_SSELCR\_REG[0] SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST\_CH0/CH1\_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.ST\_SSELCR\_REG[0] SIDETONEEN from 0 to 1 triggers this initialization process).

---

**Note:** After reset, the McBSPi.ST\_SSELCR\_REG[0] SIDETONEEN bit is 0.

---

#### 21.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the LSBs are truncated.

#### 21.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled, the McBSPi.ST\_IRQSTATUS\_REG[0] OVRRError bit is set and, if McBSPi.ST\_IRQENABLE\_REG[0] OVRRErrorEN bit is set to 1, the interrupt line is asserted.

## 21.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

### 21.5.1 McBSP Core

#### CAUTION

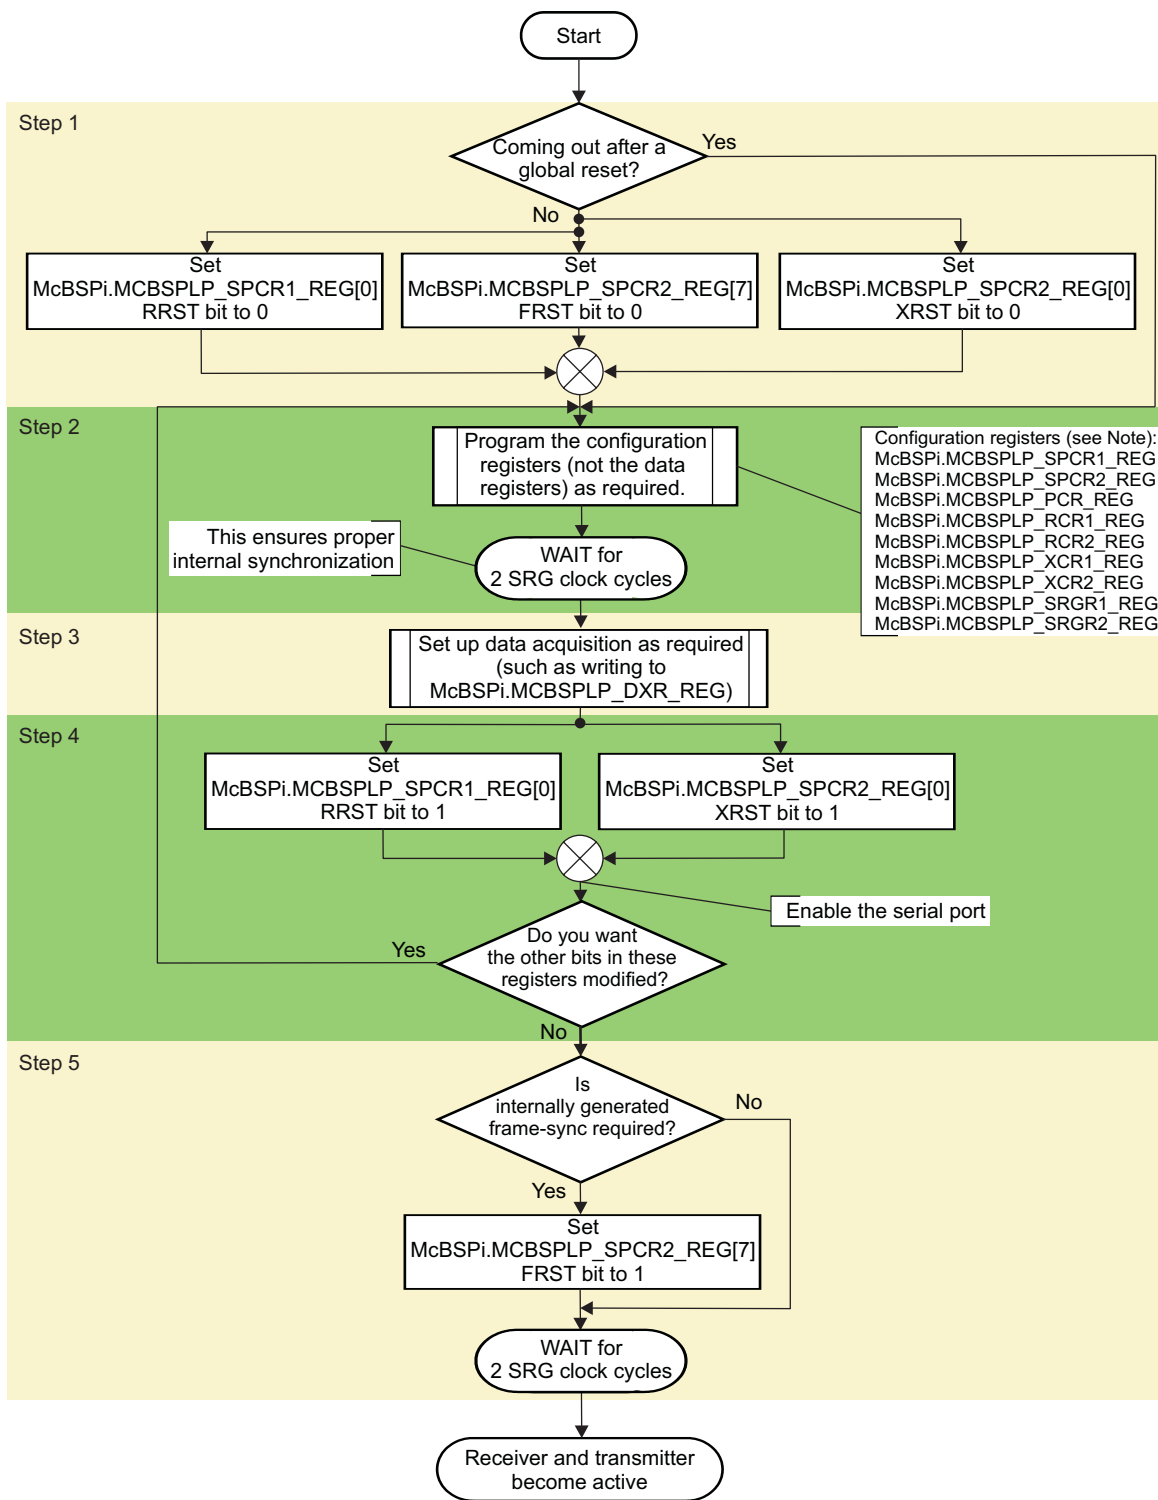

For all descriptions in this section, the McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit and the McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit are their reset value (XFULL\_CYCLE bit=0 and RFULL\_CYCLE bit=1).

#### 21.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

[Figure 21-57](#) shows the serial port initialization procedure for master mode.

Figure 21-57. Flow Diagram of McBSP Initialization Procedure for Master Mode

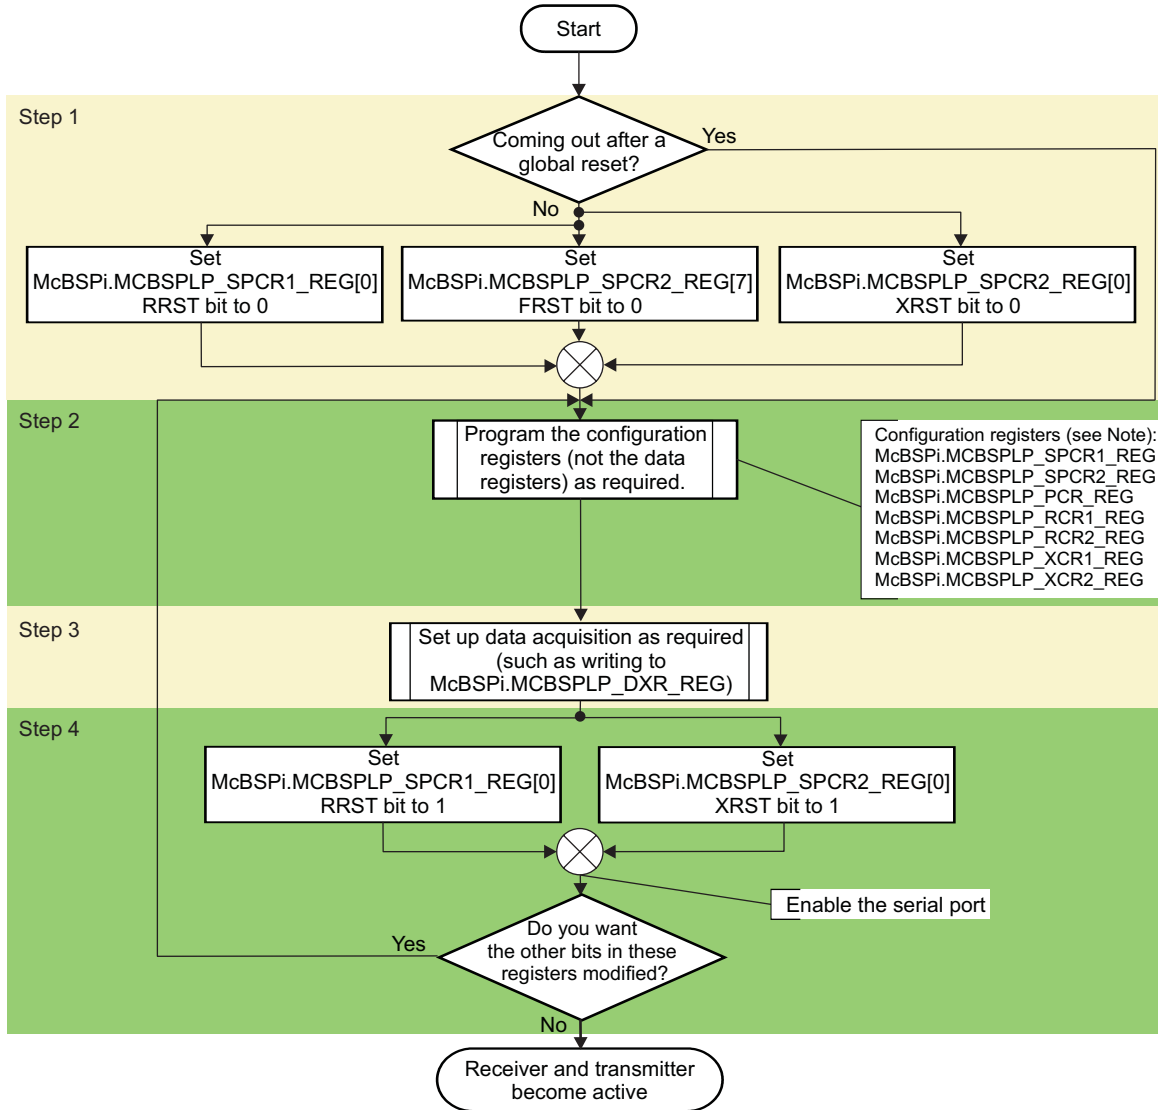

mcbasp-062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit and the McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit, respectively.

Figure 21-58 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 21-58. Flow Diagram of McBSP Initialization Procedure for Slave Mode

mcbasp-074

**Notes:**

- The necessary duration of the active-low period of XRST or Rrst is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP\_SPCR1\_REG, McBSPi.MCBSPLP\_SPCR2\_REG, McBSPi.MCBSPLP\_PCR\_REG, McBSPi.MCBSPLP\_RCR1\_REG, McBSPi.MCBSPLP\_RCR2\_REG, McBSPi.MCBSPLP\_XCR1\_REG, McBSPi.MCBSPLP\_XCR2\_REG, McBSPi.MCBSPLP\_THRSH2\_REG, McBSPi.MCBSPLP\_XCCR\_REG, McBSPi.MCBSPLP\_SYSCONFIG\_REG, McBSPi.MCBSPLP\_SRGR1\_REG, and McBSPi.MCBSPLP\_SRGR2\_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP\_DXR\_REG) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP\_MCR1\_REG, McBSPi.MCBSPLP\_MCR2\_REG, McBSPi.MCBSPLP\_RCER{A-H}\_REG and McBSPi.MCBSPLP\_XCER{A-H}\_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- Modification on-the-fly has no effect if a reset is not done first.

**21.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator**

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.

During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, Rrst, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.MCBSPLP\_SPCR1\_REG[0] Rrst=0) and reset the Transmitter (McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit =0).

- Program the registers that affect the Sample Rate Generator.

Program the Sample Rate Generator registers (McBSPi.MCBSPLP\_SPCR1\_REG and McBSPi.MCBSPLP\_SPCR2\_REG) as required for your application. Refer to [Figure 21-59](#).

If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. [Table 21-24](#) presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

**Table 21-24. McBSP Configuration in Function of the SRG Clock Source Selected**

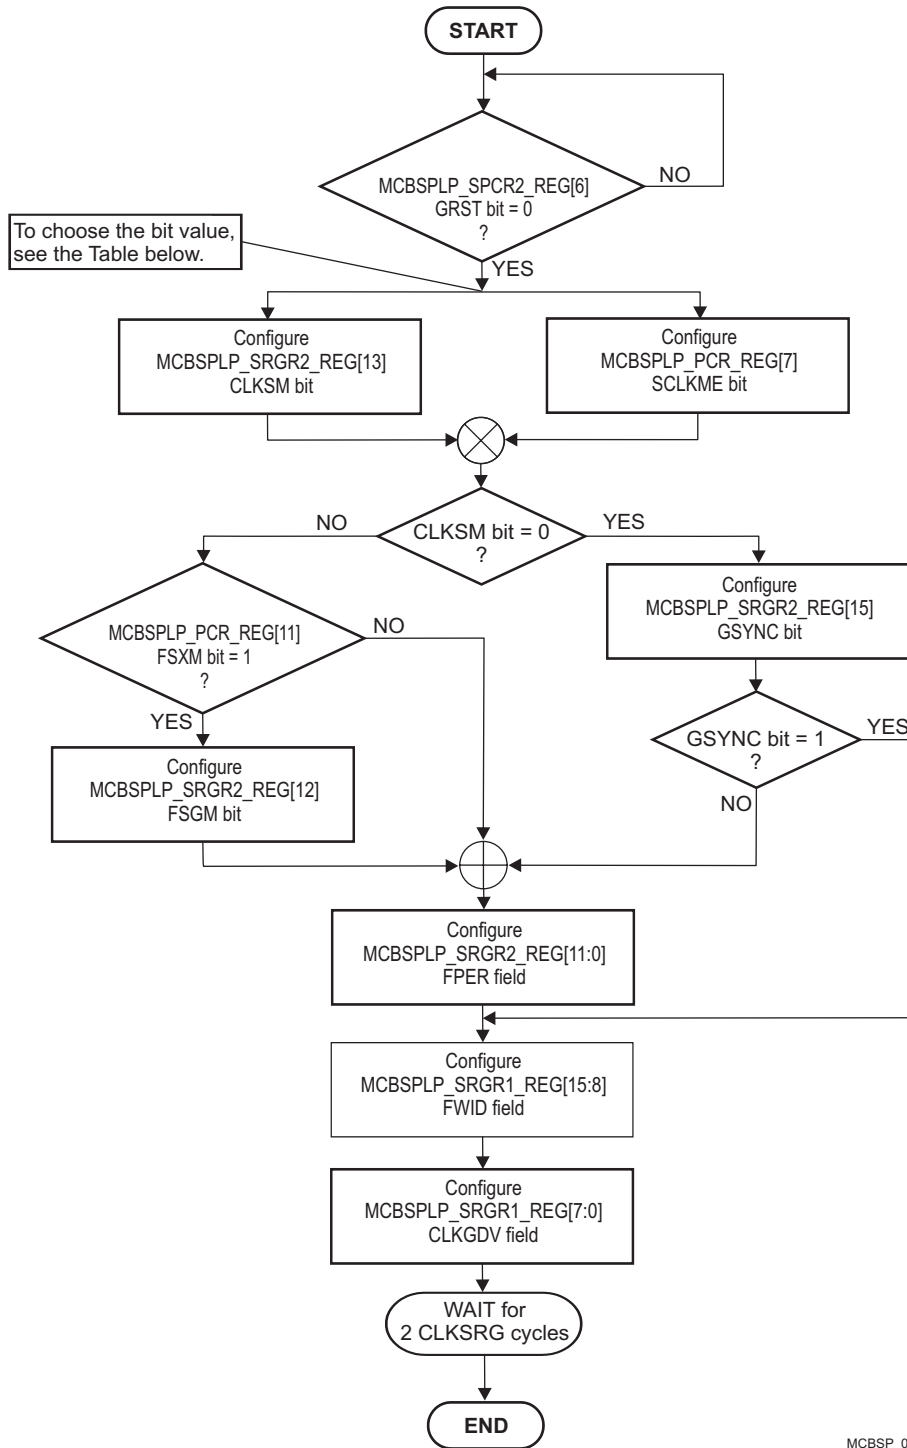

SRG Clock Source Selected	Module Configuration	McBSPi.MCBSPLP_PCR_REG Configuration			
		CLKRM bit <sup>(1)</sup>	CLKXM bit	FSRM bit <sup>(1)</sup>	FSXM bit
McBSPi_ICLK or CLKS	Master Transmitter and Slave Receiver	0	1	0	1
	Master Receiver and Slave Transmitter	1	0	1	0
	Master Transmitter and Receiver	1	1	1	1
CLKR	Master Transmitter and Slave Receiver	0	1	0	1
CLKX	Master Receiver and Slave Transmitter	1	0	1	0

<sup>(1)</sup> This configuration is correct if McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi\_clk pin) is driven by the CLKX clock, which is based on the CLKXM bit.

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).  
Set McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit to 1 to enable the Sample Rate Generator.  
After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.  
On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1).
- If necessary, enable the receiver and/or the transmitter.  
If necessary, remove the receiver and/or transmitter from reset by setting McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit and/or McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST = 1.

Figure 21-59. Flow Diagram for the SRG Registers Programming

MCBSP\_073

The input clock is selected with the McBSPi.MCBSPLP\_PCR\_REG[7] SCLKME bit and the McBSPi.MCBSPLP\_SRGR2\_REG[13] CLKSM bit in one of the following configurations (see Table 21-25):

**Table 21-25. Input Clock Selection for Sample Rate Generator**

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on mcbsp_clks pin
0	1	McBSPi_ICLK clock
1	0	Signal on mcbsp_clkr pin
1	1	Signal on mcbsp_clkx pin

### 21.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi\_DMA\_RX and McBSPi\_DMA\_TX), perform the following procedure:

- Write the receive McBSPi.MCBSPLP\_THRSH1\_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1\_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1\_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

---

**Note:** In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.MCBSPLP\_IRQENABLE\_REG[4] RUNDLEN bit.

---

- Write the transmit McBSPi.MCBSPLP\_THRSH2\_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2\_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2\_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

---

**Note:** In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.MCBSPLP\_IRQENABLE\_REG[12] XOVLEN bit.

---

### 21.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

#### 21.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.MCBSPLP\_IRQENABLE\_REG register. When the McBSPi.MCBSPLP\_IRQSTATUS\_REG bit is set and the corresponding McBSPi.MCBSPLP\_IRQENABLE\_REG bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

- Transmit buffer empty at end of frame (McBSPi.MCBSPLP\_IRQSTATUS\_REG[14] XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty).
- Transmit buffer overflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[12] XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
- Transmit buffer underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDFLSTAT bit is set to one when the transmit data buffer is empty, new data needs to be transmitted).

4. Transmit buffer threshold reached (McBSPi.MCBSPLP\_IRQSTATUS\_REG[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2\_REG + 1] value).
5. Transmit end of frame (McBSPi.MCBSPLP\_IRQSTATUS\_REG[9] XEOF is set to one when a complete frame was transmitted).
6. Transmit frame synchronization (McBSPi.MCBSPLP\_IRQSTATUS\_REG[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
7. Transmit frame synchronization Error (McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
8. Receive buffer overflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
9. Receive buffer underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[4] RUNDLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
10. Receive buffer threshold Reached (McBSPi.MCBSPLP\_IRQSTATUS\_REG[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1\_REG + 1] value).
11. Receive end of frame (McBSPi.MCBSPLP\_IRQSTATUS\_REG[2] REOF is set to one when a complete frame was received).
12. Receive frame synchronization (McBSPi.MCBSPLP\_IRQSTATUS\_REG[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
13. Receive frame synchronization error (McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

#### **21.5.1.4.2 Legacy Interrupt Line**

McBSPi\_IRQ\_TX and McBSPi\_IRQ\_RX are legacy interrupt. Not to be used for new development. McBSPi\_IRQ (common interrupt line) should be preferred.

##### **21.5.1.4.2.1 Set the receive interrupt line (legacy only)**

The McBSPi.MCBSPLP\_SPCR1\_REG[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi\_IRGQ\_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi\_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt .
- RINTM = 0b11: The receive interrupt generated when McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 21.4.4.3](#).

The McBSP module also provides a common interrupt line McBSPi\_IRQ, which can be used by setting the McBSPi.MCBSPLP\_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP\_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting
- REOFEN is equivalent with RINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- RFSREN is equivalent with RINTM = 0b10 setting

- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP\_IRQSTATUS\_REG.

#### 21.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The McBSPi.MCBSPLP\_SPCR2\_REG[5:4] XINTM bit field determines which event generates a transmit interrupt request (McBSPi\_IRQ\_TX) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi\_ICLK clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see [Section 21.4.4.6](#).

The McBSP module provides also a common interrupt line McBSPi\_IRQ, which can be used by setting the McBSPi.MCBSPLP\_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP\_IRQENABLE register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP\_IRQSTATUS\_REG.

#### 21.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

##### 21.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST, McBSPi.MCBSPLP\_SPCR2\_REG[7] FRST, McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST and McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.

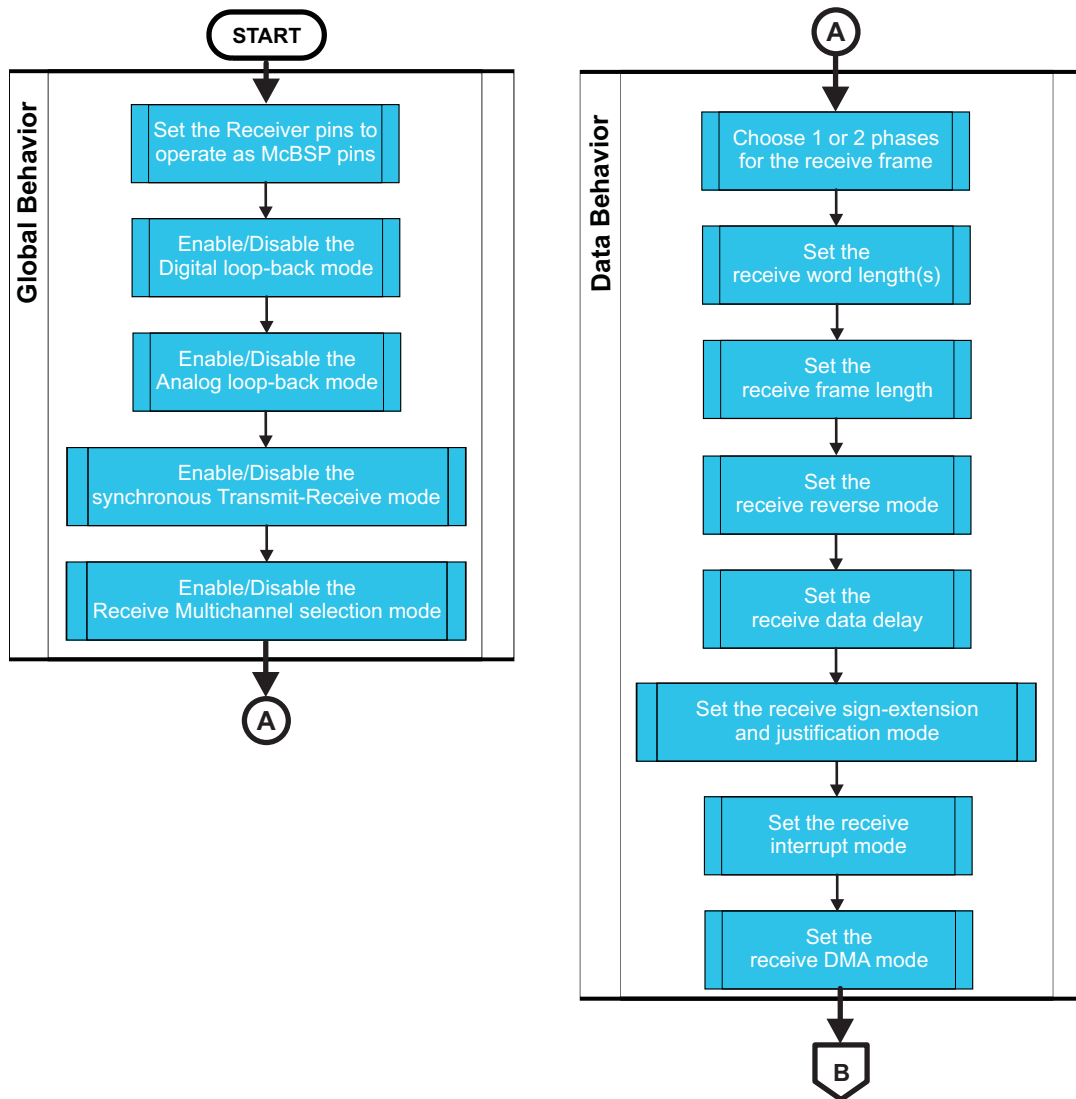

- The serial port receiver can be reset directly using the `McBSPi.MCBSPLP_SPCR1_REG[0]` RRST bit. If the SRG needs to be used, SRG must be reset directly using the `McBSPi.MCBSPLP_SPCR2_REG[6]` GRST bit. Similar operations with frame synchronization generator also require using the `McBSPi.MCBSPLP_SPCR2_REG[7]` FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

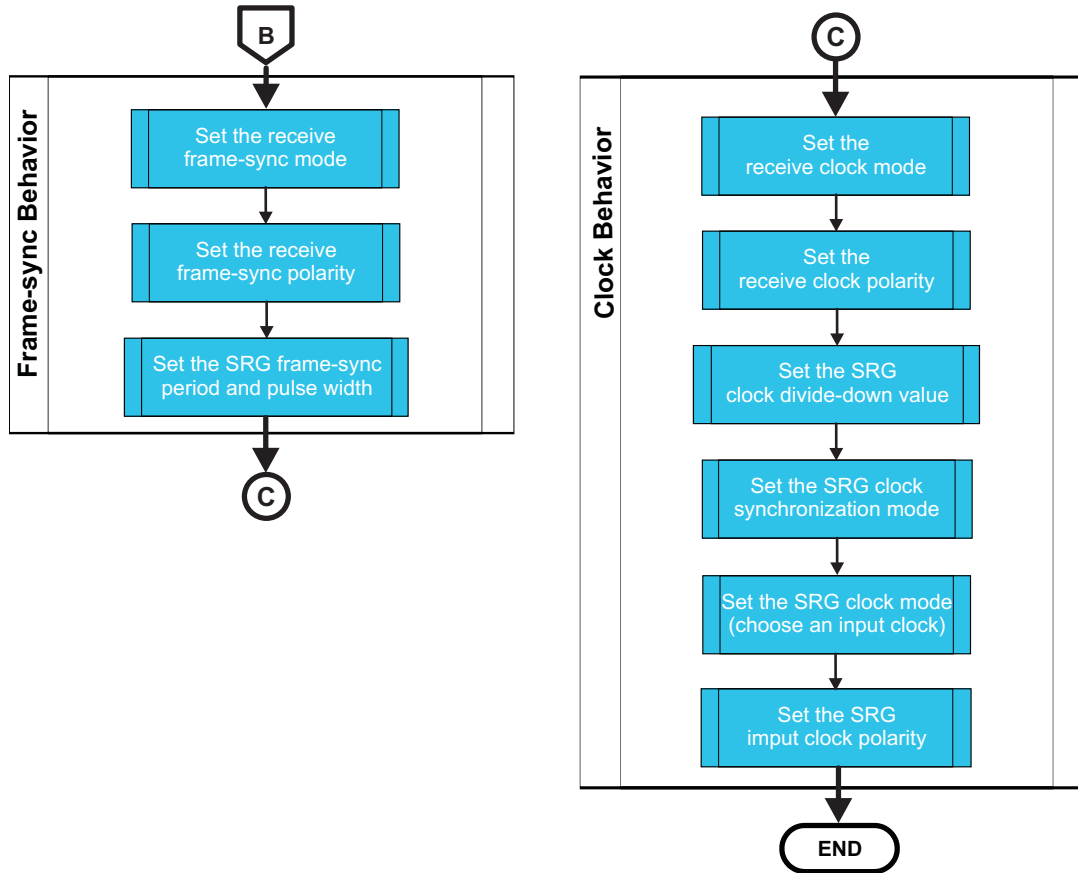

### 21.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 21-60 and Figure 21-61 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 21-60. Important Tasks to Configure the McBSP Receiver (Part 1)

063

**Figure 21-61. Important Tasks to Configure the McBSP Receiver (Part 2)**

064

### 21.5.1.5.2.1 Global Behavior

#### 21.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.MCBSPLP\_PCR\_REG[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general-purpose I/O pins (RIOEN bit=1).

Please refer to [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

#### 21.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

---

**Note:** That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

---

### 21.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.MCBSPLP\_SPCR1\_REG[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

### 21.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The McBSP1\_CLKR bit of the CONTROL\_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The McBSP1\_FSR bit of the CONTROL\_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

### 21.5.1.5.2.1.5 Enable/Disable the Receive Multichannel Selection Mode

The McBSPi.MCBSPLP\_MCR1\_REG[0] RMCM bit determines whether the receive multichannel selection mode is on or off.

For further details, see [Section 21.4.6.5](#).

### 21.5.1.5.2.2 Data Behavior

#### 21.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

#### 21.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

#### 21.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLLEN1 and McBSPi.MCBSPLP\_RCR2\_REG[14:8] RFRLLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words (one word for phase 1 plus the one word for phase 2). Other values must not be used.

The 7-bit RFRLN1 field allows up to 128 words per phase when single-phase frame. See [Table 21-26](#) below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLN fields with  $[W - 1]$ , where  $W$  represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFRLN1.

**Table 21-26. How to Calculate the Length of the Receive Frame**

RPHASE	RFRLN1	RFRLN2	Frame Length
0	$0 \leq \text{RFRLN1} \leq 127$	Don't care	(RFRLN1value + 1) words
1	RFRLN1 = 0	RFRLN2 = 0	2 words

#### 21.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.MCBSPLP\_RCR2\_REG[4:3] RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see [Section 21.4.2.2](#).

#### 21.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY=0b00–0b10), as shown in [Figure 21-62](#) below. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

**Figure 21-62. Range of Programmable Data Delay**

##### 21.5.1.5.2.2.5.1 0-Bit Data Delay

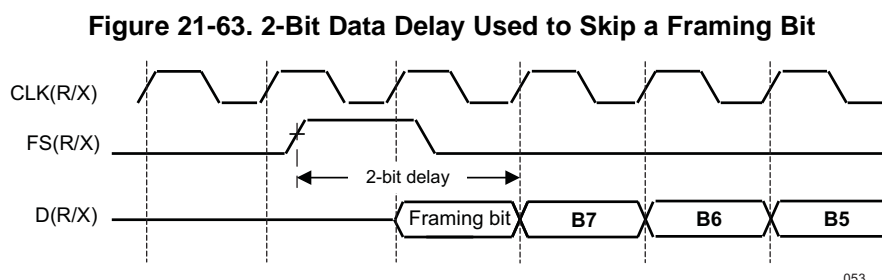

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR

where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbasp\_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbasp\_dx pin.

### 21.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-63. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

### 21.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.MCBSPLP\_SPCR1\_REG[14:13] RJUST bit field determines whether data received by the McBSP module is sign-extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.MCBSPLP\_DRR\_REG register and whether unused bits in McBSPi.MCBSPLP\_DRR\_REG are filled with zeroes or with sign bits.

Table 21-27 and Table 21-28 show the effects of various RJUST values; the effect on an example 12-bit receive-data value 0xABC, and the effect on an example 20-bit receive-data value 0xABCDE, respectively.

**Table 21-27. Example: Use of RJUST Bit Field With 12-bit Data Value 0xABC**

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x0000 0ABC
0b01	Right	Sign extend data into MSBs	0xFFFF FABC
0b10	Left	Zero fill LSBs	0xABC0 0000
0b11	Reserved	Reserved	Reserved

### 21.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to Section 21.5.1.4.2.1.

### 21.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi\_DMA\_RX) are active after the McBSPi.MCBSPLP\_SPCR1\_REG [0] RRST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.MCBSPLP\_RCCR\_REG[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.MCBSPLP\_THRSH1\_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1\_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1\_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

### 21.5.1.5.2.3 Frame-Sync Behavior

#### 21.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit, McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit, McBSPi.MCBSPLP\_SPCR1\_REG[15] ALB bit and McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbbsp\_fsr pin.

Table 21-29 below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbbsp\_fsr pin. The polarity of the signal on the mcbbsp\_fsr pin is determined by the McBSPi.MCBSPLP\_PCR\_REG[2] FSRP bit.

**Table 21-29. FSRM and GSYNC Effects on Frame-Sync Signal and mcbbsp\_fsr Pin**

FSRM	GSYNC	Source of Receive Frame Synchronization	MCBSPLP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP module through the mcbbsp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR.	Input
1	0	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbbsp_fsr pin.
1	1	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the mcbbsp_fsr pin is used to synchronize CLKG and generate FSG pulses.

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see [Section 21.4.3](#).

#### 21.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The McBSPi.MCBSPLP\_PCR\_REG[2] FSRP bit determines whether frame-synchronization pulses are active high or active low on the mcbbsp\_fsr pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit. FSR is also affected by the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit. For information about the effects of FSRM and GSYNC, see [Section 21.5.1.5.2.3.1](#), *Set the Receive Frame-Sync Mode*.

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbspi\_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the mcbbsp\_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (McBSPi.MCBSPLP\_PCR\_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

Figure 21-64 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 21-64. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

### 21.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER bit field is used to set the SRG frame-sync period and McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID bit field is used to set the SRG pulse width.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER+1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC=1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID+1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 21-65 shows a frame-synchronization period of 16 CLKG periods (FPER=15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID=1).

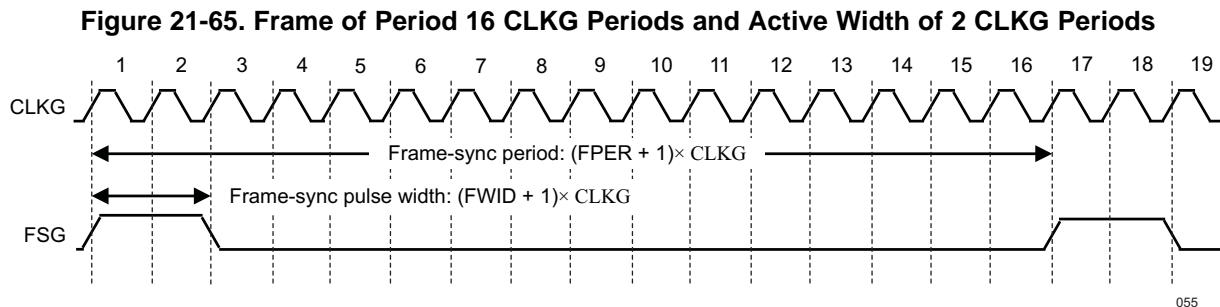

Figure 21-65. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods

When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

#### 21.5.1.5.2.4 Clock Behavior

##### 21.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit, McBSPi.MCBSPLP\_SPCR1\_REG[15] ALB bit and McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit are used to set the receive clock mode.

Table 21-30 shows how to select various sources to provide the receive clock signal and affect the mcbssp\_clkr pin. The McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit determines the polarity of the signal on the mcbssp\_clkr pin.

**Table 21-30. CLKRM Effect on Receive Clock Signal and mcbssp\_clkr Pin**

CLKRM	Source of Receive Clock	mcbssp_clkr Pin Status
0	The mcbssp_clkr pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used.	Input
1	The SRG clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbssp_clkr pin.

In the digital loop-back mode (DLB=1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see [Section 21.4.3.1](#).

##### 21.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbssp\_clkr pin.

---

**Note:** CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

---

##### 21.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to  $1/(\text{CLKGDV}+1)$  of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

##### 21.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see [Section 21.4.3](#).

#### **21.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)**

McBSPi.MCBSPLP\_PCR\_REG[7] SCLKME bit and McBSPi.MCBSPLP\_SRGR2\_REG[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see [Section 21.4.3](#).

#### **21.5.1.5.2.4.6 Set the SRG Input Clock Polarity**

McBSPi.MCBSPLP\_SRGR2\_REG[14] CLKSP bit, McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP bit and McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP\_FCLK clock or from an external clock on the mcbasp\_clks, mcbasp\_clkx, or mcbasp\_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbasp\_clks pin, CLKXP for the mcbasp\_clkx pin, CLKRP for the mcbasp\_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

### **21.5.1.6 Transmitter Configuration**

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

#### **21.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter**

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

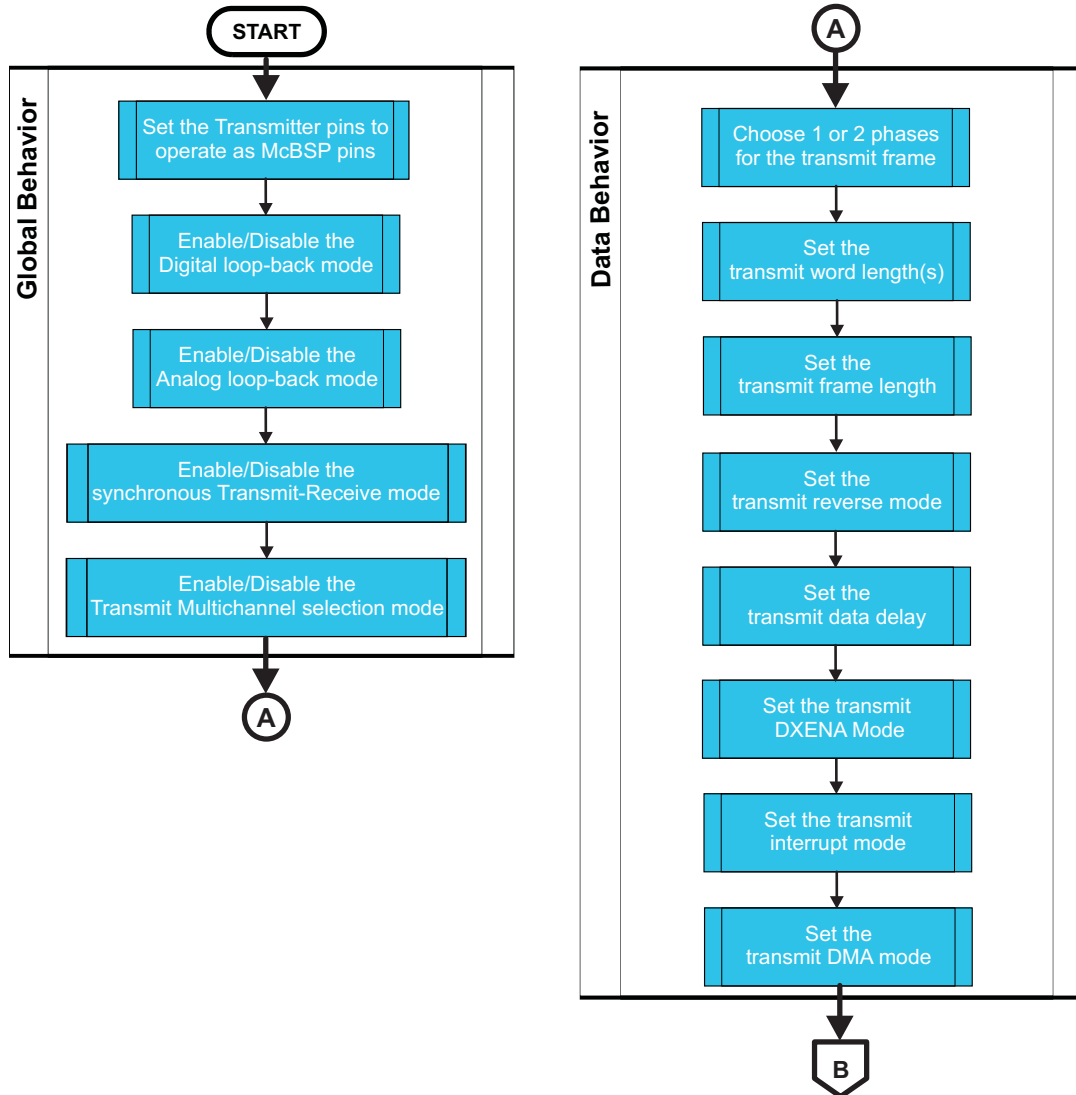

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST, McBSPi.MCBSPLP\_SPCR2\_REG[7] FRST, McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST and McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit. Similar operation with the Frame Synchronization Generator also requires using the McBSPi.MCBSPLP\_SPCR2\_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

### 21.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 21-66 and Figure 21-67 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

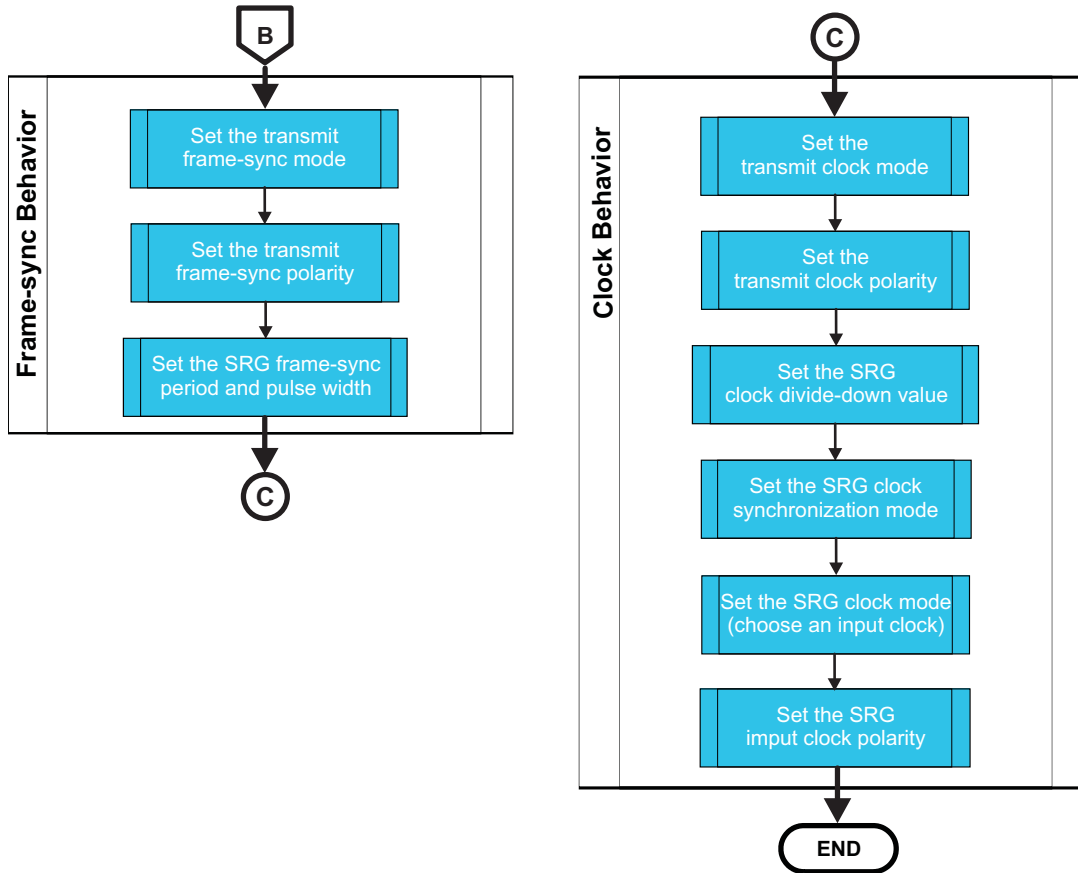

Figure 21-66. Important Tasks to Configure the McBSP Transmitter (Part 1)

065

Figure 21-67. Important Tasks to Configure the McBSP Transmitter (Part 2)

066

### 21.5.1.6.2.1 Global Behavior

#### 21.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.MCBSPLP\_PCR\_REG[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general-purpose I/O pins (XIOEN=1).

Refer to [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

#### 21.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

Refer to it, [Section 21.5.1.5.2.1.2](#).

#### 21.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

Refer to it, [Section 21.5.1.5.2.1.3](#).

#### 21.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

Refer to it, [Section 21.5.1.5.2.1.4](#).

#### 21.5.1.6.2.1.5 Enable/Disable the Transmit Multichannel Selection

McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM bit field determines whether the transmit multichannel selection mode is on or off.

Refer to [Section 21.4.6.7](#).

### 21.5.1.6.2.2 Data Behavior

#### 21.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

#### 21.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

#### 21.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP\_XCR2\_REG[14:8] XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual-phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7-bit XFRLEN fields allow up to 128 words per phase. See [Table 21-31](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

**Table 21-31. How to Calculate the Length of the Transmit Frame**

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	$0 \leq \text{XFRLEN1} \leq 127$	Don't care	(XFRLEN1value +1) words
1	XFRLEN1= 0	XFRLEN2 = 0	2 words

#### 21.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.MCBSPLP\_XCR2\_REG[4:3] XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see [Section 21.4.2.2](#).

#### 21.5.1.6.2.2.5 Set the Transmit Data Delay

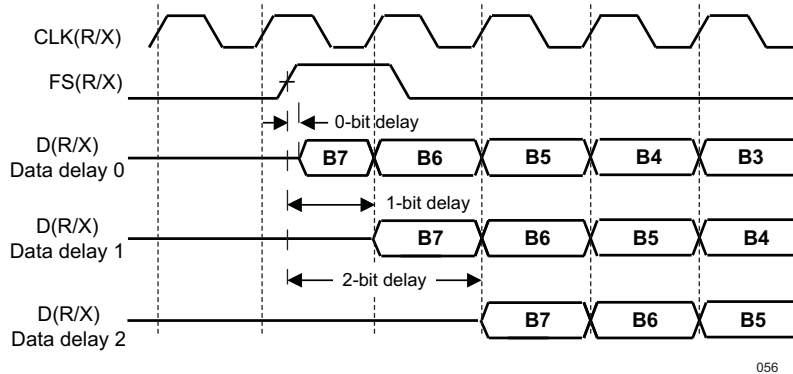

McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (XDATDLY=00b–10b), as shown in [Figure 21-68](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

**Note:** Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

**Figure 21-68. Range of Programmable Data Delay**

**21.5.1.6.2.2.5.1 0-Bit Data Delay:**

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi\_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbbsp\_dx pin.

**21.5.1.6.2.2.5.2 2-Bit Data Delay:**

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-69. The data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

**Figure 21-69. 2-Bit Data Delay Used to Skip a Framing Bit**

**21.5.1.6.2.2.6 Set the Transmit DXENA Mode**

McBSPi.MCBSPLP\_SPCR1\_REG[7] DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbbsp\_dx pin. Set DXENA to enable an extra delay for

turn-on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 7 ns, 14 ns (default), 20 ns or 28 ns can be set using the McBSPi.MCBSPLP\_XCCR\_REG[13:12] DXENDLY field. If you tie together the mcbbsp\_dx pins of multiple McBSP modules, make sure DXENA=1, to avoid having more than one McBSP transmitting on the data line at one time.

#### 21.5.1.6.2.7 Set the Transmit Interrupt Mode

Refer to [Section 21.5.1.4.2.2](#).

#### 21.5.1.6.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (McBSPi\_DMA\_TX) are active after the transmit McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the McBSPi.MCBSPLP\_XCCR\_REG[3] XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit McBSPi.MCBSPLP\_THRSH2\_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the THRSH2\_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH2\_REG value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

#### 21.5.1.6.2.3 Frame-Synchronization Behavior

##### 21.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit and McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM bit are used to set the transmit frame-sync mode.

[Table 21-32](#) shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

[Table 21-32](#) also shows the effect of each bit setting on the mcbbsp\_fsx pin. The FSXP bit determines the polarity of the signal on the mcbbsp\_fsx pin.

**Table 21-32. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses**

FSXM	FSGM	Source of Transmit Frame Synchronization	mcbbsp_fsx Pin Status
0	0 or 1	An external FSG enters the McBSP through the mcbbsp_fsx pin. The signal is then inverted by FSXP bit before being used as internal FSX.	Input
1	1	Internal FSX is driven by the SRG FSG.	Output. FSG is inverted by FSXP bit before being driven out on mcbbsp_fsx pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on mcbbsp_fsx pin.

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the `mcbasp_fsr` pin. For more details, see [Section 21.4.3.3](#).

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see [Section 21.4.3.2](#).

#### 21.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

McBSPi.MCBSPLP\_PCR\_REG[3] FSXP bit determines whether frame-synchronization pulses are active high or active low on the `mcbasp_fsx` pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit. FSX is also affected by the McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM bit. For information about the effects of FSXM and FSGM, see [Section 21.5.1.6.2.3.1](#).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the `mcbasp_dr` pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the `mcbasp_dx` pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR\_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active-high FSG are inverted before being sent to the FS(R/X) pin.

#### 21.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See [Section 21.5.1.5.2.3.3](#).

#### 21.5.1.6.2.4 Clock Behavior

##### 21.5.1.6.2.4.1 Set the Transmit Clock Mode

The McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM bit is used to set the transmit clock mode.

[Table 21-33](#) shows how the CLKXM bit selects the transmit clock and the corresponding status of the `mcbasp_clkx` pin. The CLKXP bit determines the polarity of the signal on the `mcbasp_clkx` pin.

**Table 21-33. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin**

CLKXM	Source of Transmit Clock	mcbasp_clkx Pin Status
0	Internal CLKX is driven by an external clock on the <code>mcbasp_clkx</code> pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the SRG clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on <code>mcbasp_clkx</code> .

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the mcbbsp\_fsr pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see [Section 21.4.3.1](#).

#### 21.5.1.6.2.4.2 Set the Transmit Clock Polarity

The McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the mcbbsp\_clkx pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbbsp\_clkr pin.

---

**Note:** CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

---

See [Section 21.5.1.5.2.4.6](#).

### 21.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

[Table 21-34](#) summarizes how to use the McBSP pins as general-purpose I/O pins. All the bits mentioned in the table except XRST and RRST bits are in the pin control register (McBSPi.MCBSPLP\_PCR\_REG). McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit and McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit are in the serial port control registers.

To use receiver pins mcbbsp\_clkr, mcbbsp\_fsr, and mcbbsp\_dr as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit =0).
2. General-purpose I/O is enabled for the serial port receiver (McBSPi.MCBSPLP\_PCR\_REG[12] RIOEN=1).

The `mcbasp_clkr` and `mcbasp_fsr` pins can be individually configured as either input or output pins with the `CLKRM` and `FSRM` bits, respectively. The `mcbasp_dr` pin can only be an input pin. [Table 21-34](#) shows, which bits in `McBSPi.MCBSPLP_PCR_REG` are used to read from/write to these pins.

For the transmitter pins `mcbasp_clkx`, `mcbasp_fsx`, and `mcbasp_dx`, you must meet two conditions:

1. The transmitter of the serial port is in reset (`McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0`).
2. General-purpose I/O is enabled for the serial port transmitter (`McBSPi.MCBSPLP_PCR_REG[12] XIOEN=1`).

The `mcbasp_clkx` and `mcbasp_fsx` pins can be individually configured as input or output pins with the `CLKXM` and `FSXM` bits, respectively. The `mcbasp_dx` pin can only be an output pin. [Table 21-34](#) shows the bits in `McBSPi.MCBSPLP_PCR_REG` used to read from/write to these pins.

For the `mcbasp_clks` pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (`RRST=0` and `XRST=0`).
2. General-purpose I/O is enabled for both the receiver and the transmitter (`RIOEN=1` and `XIOEN=1`).

The `mcbasp_clks` pin can only be an input pin. To read the status of the signal on the `mcbasp_clks` pin, read the `McBSPi.MCBSPLP_PCR_REG[6] CLKS_STAT` bit.

**Table 21-34. Using McBSP Pins for General-Purpose I/O**

Pin	General-Purpose use enabled by this bit combination	Selected as output when	Output value driven from this bit	Selected as input when	Input value read from this bit
<code>mcbasp_clkx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	<code>CLKXM = 1</code>	<code>CLKXP</code>	<code>CLKXM = 0</code>	<code>CLKXP</code>
<code>mcbasp_fsx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	<code>FSXM = 1</code>	<code>FSXP</code>	<code>FSXM = 0</code>	<code>FSXP</code>
<code>mcbasp_dx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	Always	<code>DX_STAT</code>	Never	Does not apply
<code>mcbasp_clkr</code>	<code>RRST = 0</code> <code>RIOEN = 1</code>	<code>CLKRM = 1</code>	<code>CLKRP</code>	<code>CLKRM = 0</code>	<code>CLKRP</code>
<code>mcbasp_fsr</code>	<code>RRST = 0</code> <code>RIOEN = 1</code>	<code>FSRM = 1</code>	<code>FSRP</code>	<code>FSRM = 0</code>	<code>FSRP</code>

### 21.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

#### 21.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in [Figure 21-70](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from `McBSPi.MCBSPLP_DRR_REG` and four writes to `McBSPi.MCBSPLP_DXR_REG` are necessary for each frame.

**Figure 21-70. Four 8-bit Data Words Transferred To/From McBSP Module**

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in [Figure 21-71](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from `McBSPi.MCBSPLP_DRR_REG` and two writes to `McBSPi.MCBSPLP_DXR_REG` are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

**Figure 21-71. One 32-bit Data Word Transferred To/From McBSP Module**

### 21.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. [Figure 21-72](#) shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

**Figure 21-72. 8-bit Data Words Transferred at Maximum Packet Frequency**

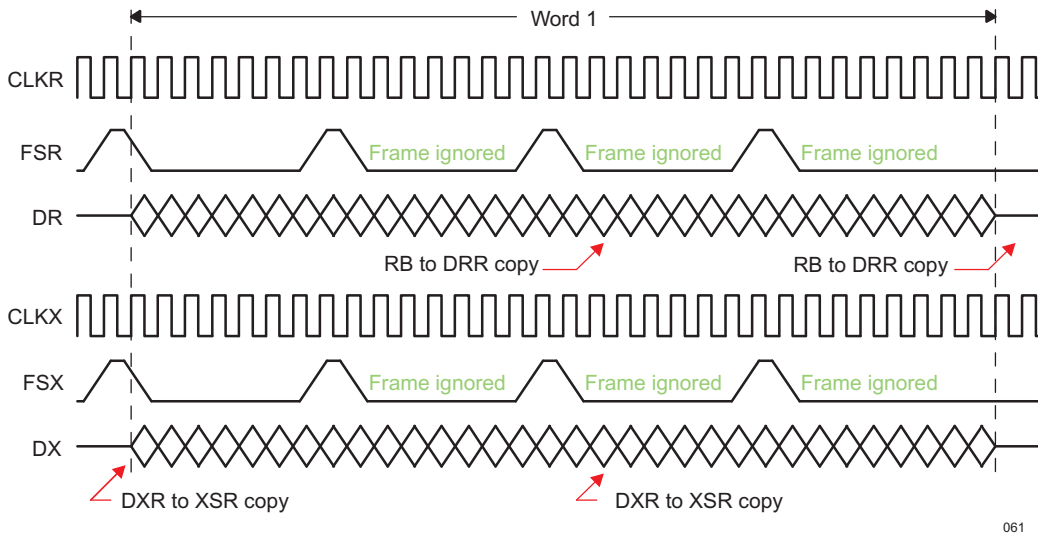

Figure 21-73 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

**Figure 21-73. Configuring the Data Stream as a Continuous 32-bit Word**

## 21.5.2 SIDETONE Feature

### 21.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel mode of the McBSP module:

- Select a single-phase frame (McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit and McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.MCBSPLP\_MCR1\_REG[0] RMCM bit, to select multichannel mode enable.
- Set a frame length (McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLN1 bit field and McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 bit field and McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note

below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in [Table 21-35](#):

**Table 21-35. Selection of the SIDETONE Input and Output Channels**

Bit field	Description
McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN	Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN	Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN	Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)
McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN	Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)

- Enable SIDETONE by setting 2 bits to 1:
  1. In McBSP module, the McBSPi.MCBSPLP\_SSELCR\_REG[10] SIDETONEEN bit
  2. In SIDETONE core, the McBSPi.ST\_SSELCR\_REG[0] SIDETONEEN bit

---

**Note:** Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

---

### 21.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.ST\_SSELCR\_REG[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.ST\_SFIRCR\_REG[15:0] FIRCOEFF bit field, the McBSPi.ST\_SFIRCR\_REG[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.ST\_SSELCR\_REG[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.ST\_SGAINCR\_REG[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.ST\_SGAINCR\_REG[15:0] CH0GAIN bit field for the first sidetone channel.

### 21.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.ST\_SSELCR\_REG[1] COEFFWREN bit to enable writing of the FIR coefficients, or write 0, and then write 1 in the COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on the McBSPi.ST\_SFIRCR\_REG[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.ST\_SSELCR\_REG[2] COEFFWRDONE bit (it becomes 1 after the 128th coefficient is written).

### 21.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.ST\_SSELCR\_REG[1] COEFFWREN bit to enable reading of the FIR coefficients, or write 1, and then write 0 in the COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.ST\_SFIRCR\_REG[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

## 21.6 McBSP Use Case and Tips

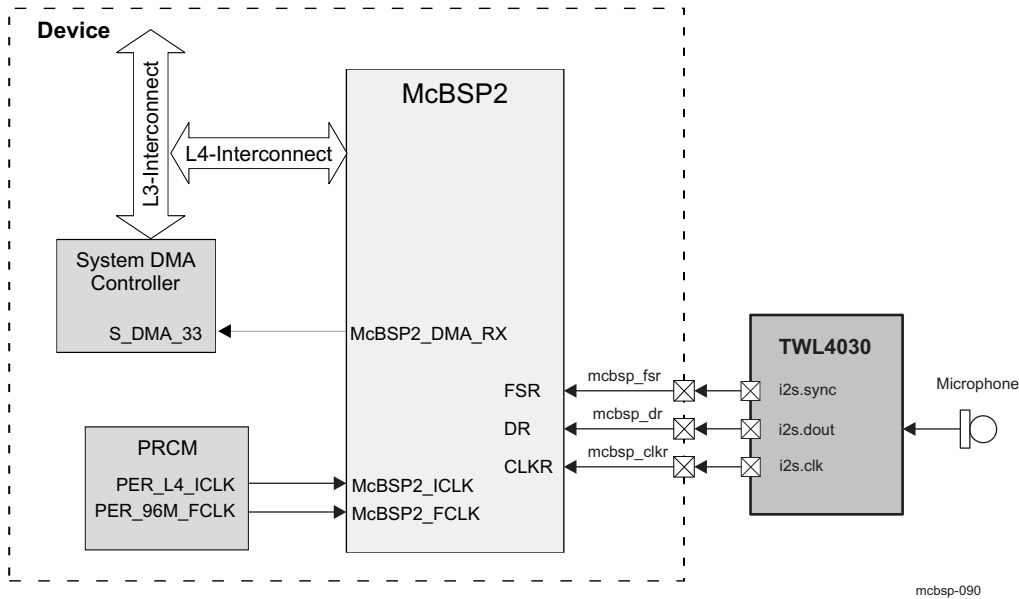

### 21.6.1 Camcorder Use Case: How to Configure the McBSP2 to Receive Voice Stream From the TWL4030 Device

#### 21.6.1.1 Overview

In the camcorder use case, the McBSP2 is used to transfer voice from the TWL4030 device to external DRAM through the sDMA controller. The McBSP2 module is directly connected to the TWL4030 device in slave mode (that is, the TWL4030 generates clock and FSR signals to manage data).

Figure 21-74 is an overview of the voice path.

Figure 21-74. Overview

mcbbsp-090

The TWL4030 device samples audio data at 16 kHz/16 bits in stereo. In the camcorder user case, a monophonic microphone is plugged on one channel of the TWL4030 device. Although only one channel is used, both left and right audio channels are transmitted to the McBSP. Moreover, the 16-bit channels are transmitted on two 32-bit words for this use case. The result is an I2S format with the following properties:

- Word width = 16 bits
- Sample length = 2 x 32 bits (two channels at 16 bits over 32 bits)
- Right-justified data format (zero-fill MSBs)

The TWL4030 device transmits two 32-bit frames that correspond to the two channels of a stereo signal, one on the low level of the frame synchronization signal, and the other on the high level. The microphone is monophonic; therefore, the McBSP2 is configured to receive only the right channel. Figure 21-75 shows the input data, CLKR, and FSR signal from the TWL4030 device.

Figure 21-75. I2S Format

mcbbsp-091

### 21.6.1.2 Programming Flow

The McBSP2 is configured as a slave receiver device driven by the TWL4030 device. It is configured to receive input data (see [Figure 21-75](#)). When the configuration is complete, the sDMA controller can transfer data from [MCBSPLP\\_DRR\\_REG](#) to the external DRAM.

First, the correct functional clock must be selected in the system control module. The [MCBSP2\\_CLKS](#) bit of the [CONTROL.CONTROL\\_DEVCONF0\[6\]](#) register is set to 0 to make [PER\\_96M\\_FCLK](#) the functional clock of the module (CLKS).

Next, the McBSP2 clocks are enabled on the PRCM:

- Enable the functional clock: [PRCM.CM\\_FLCKEN\\_PER\[0\]](#) = 1
- Enable the interface clock: [PRCM.CM\\_ILCKEN\\_PER\[0\]](#) = 1

Then, the initialization procedure is followed (see [Figure 21-57](#)):

1. Put the receiver and frame-sync generator under reset:
  - [MCBSPLP\\_SPCR1\\_REG\[0\]](#) RRST = 0
  - [MCBSPLP\\_SPCR2\\_REG\[7\]](#) FRST = 0
2. Program the configuration registers as required:
  - a. Set one phase for the receive frame (only one channel is taken in account):  
[MCBSPLP\\_RCR2\\_REG\[15\]](#) RPHASE = 0
  - b. Set the receive data delay to 0-bit data delay:  
[MCBSPLP\\_RCR2\\_REG\[1:0\]](#) RDATDLY = 0
  - c. Set Receive Word Length to 32 bits:  
[MCBSPLP\\_RCR1\\_REG\[7:5\]](#) RWDLEN1 = 5
  - d. Set the number of words per frame to 1:  
[MCBSPLP\\_RCR1\\_REG\[14:8\]](#) RFRLLEN1 = 0
  - e. Set the threshold to one-half of the FIFO size (that is, 640):  
[MCBSPLP\\_THRSH1\\_REG\[10:0\]](#) RTHRESHOLD = 0x280
  - f. Set the receive sign-extension and justification mode to right-justify and zero-fill MSBs in [MCBSPLP\\_DRR\\_REG](#):  
[MCBSPLP\\_SPCR1\\_REG\[14:13\]](#) RJUST = 0
  - g. Set the receive frame-synchronization mode, frame-synchronization pulses generated by an external device. FSR is an input pin.  
[MCBSPLP\\_PCR\\_REG\[10\]](#) FSRM = 0
  - h. Set the receive frame-synchronization polarity to active high: The channel on the high level of FSR will be received.  
[MCBSPLP\\_PCR\\_REG\[2\]](#) FSRP = 0
  - i. Set the receive clock mode: Receive clock is an input driven by an external clock with CLKR as an input pin.  
[MCBSPLP\\_PCR\\_REG\[8\]](#) CLKR = 0
  - j. Set the receive clock polarity: Receive data sampled on the falling edge of CLKR.  
[MCBSPLP\\_PCR\\_REG\[0\]](#) CLKRP = 0
  - k. Wait for two clock cycles.
3. Not applicable in receiver mode.
4. Release the receiver reset:  
[MCBSPLP\\_SPCR1\\_REG\[0\]](#) RRST = 1
5. Internally generated frame-sync is not required:
  - a. The frame-sync generator reset is not released.
  - b. Wait for two clock cycles.

[Table 21-36](#) lists the registers involved during a transfer.

**Table 21-36. McBSP2 Registers Print**

<b>Register Name</b>	<b>Address</b>	<b>Value</b>	<b>Value Description</b>

SIDETONE_McBSP3	0x4902 A000	4K bytes

### 21.7.1 McBSP Register Mapping Summary

#### CAUTION

The McBSP data registers (that is, DXR\_REG for data transmit and DRR\_REG for data receive) support 8/16/32-bit data accesses. All other McBSP registers are limited to 32-bit data accesses. 16-bit and 8-bit data accesses are not allowed and can corrupt register contents.

**Table 21-38. McBSP1 Registers Mapping Summary**

Bits	Field Name	Description	Type	Reset
1:0	XMCM	Transmit Multichannel Selection Enable  0x0: All channels enabled without masking (DX is always driven during transmission of data).  0x1: All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven.  0x2: All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked.  0x3: All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symmetric transmit and receive operation.	RW	0x0

<b>Description</b>	McBSPLP receive buffer threshold (DMA or IRQ trigger)		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												RTHRESHOLD																			

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Read returns 0x0.	R	0x000000
10:0 <sup>(1)</sup>	RTHRESHOLD	Receive buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) is triggered if the number of occupied locations in the receive buffer are above or equal to the RTHRESHOLD value + 1. Also, this value (RTHRESHOLD value + 1) indicates the number of words transferred during a receive data DMA request, if receive DMA is enabled.	RW	0x00

<sup>(1)</sup> XTHRESHOLD is an 11-bit field for McBSP2 only. For other McBSPs, XTHRESHOLD is an 8-bit field (bits 7 to 10 are reserved). In other words, the other McBSPs are limited to a FIFO width of 0x7F.

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read returns 0x0.	R	0x00000
14	XEMPTYEOF	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to one when a complete frame was transmitted and the transmit buffer is empty). Writing 1 to this bit clears the bit.  0x0: Transmit buffer NOT Empty at end of frame 0x1: Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.	RW	0x0
13	RESERVED	Read returns 0x0.	R	0x0
12	XOVFLSTAT	Transmit Buffer Overflow (XOVFLSTAT bit is set to one when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.  0x0: Transmit buffer NOT overflow 0x1: Transmit buffer overflow; Writing 1 to this bit clears the bit.	RW	0x0
11	XUNDFLSTAT	Transmit Buffer Underflow (XUNDFLSTAT bit is set to one when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit.  0x0: the transmit data buffer is NOT empty new data is required to be transmitted. 0x1: the transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.	RW	0x0
10	XRDY	Transmit Buffer Threshold Reached (XRDY bit is set to one when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.  0x0: Transmit buffer occupied locations are below the THRSH2_REG value). 0x1: Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.	RW	0x0
9	XEOF	Transmit End Of Frame (XEOF is set to one when a complete frame was transmitted). Writing 1 to this bit clears the bit.  0x0: complete frame was NOT transmitted 0x1: complete frame was transmitted; Writing 1 to this bit clears the bit.	RW	0x0
8	XFSX	Transmit Frame Synchronization (XFSX bit is set to one when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.  0x0: new transmit frame synchronization is NOT asserted 0x1: new transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.	RW	0x0

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Reset</b>
7	XSYNCERR	<p>Transmit Frame Synchronization Error (XSYNCERR is set to one when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.</p> <p>0x0: Transmit frame synchronization error is NOT detected</p> <p>0x1: Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.</p>	RW	0x0
6	RESERVED	Read returns 0x0.	R	0x0
5	ROVFLSTAT	<p>Receive Buffer Overflow (ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.</p> <p>0x0: receive buffer NOT overflow</p> <p>0x1: receive buffer overflow; Writing 1 to this bit clears the bit.</p>	RW	0x0
4	RUNDFLSTAT	<p>Receive Buffer Underflow (RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit.</p> <p>0x0: read operation is performed to the receive data register while receive buffer is NOT empty</p> <p>0x1: read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.</p>	RW	0x0
3	RRDY	<p>Receive Buffer Threshold Reached (RRDY bit is set to one when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.</p> <p>0x0: receive buffer occupied locations are below the THRSH1_REG value).</p> <p>0x1: receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.</p>	RW	0x0
2	REOF	<p>Receive End Of Frame (REOF is set to one when a complete frame was received). Writing 1 to this bit clears the bit.</p> <p>0x0: complete frame was NOT received</p> <p>0x1: complete frame was received; Writing 1 to this bit clears the bit.</p>	RW	0x0
1	RFSR	<p>Receive Frame Synchronization (RFSR bit is set to one when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit.</p> <p>0x0: new receive frame synchronization is NOT asserted</p> <p>0x1: new receive frame synchronization is asserted; Writing 1 to this bit clears the bit.</p>	RW	0x0
0	RSYNCERR	<p>Receive Frame Synchronization Error (RSYNCERR is set to one when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit.</p> <p>0x0: receive frame synchronization error is NOT detected</p> <p>0x1: receive frame synchronization error is detected. Writing 1 to this bit clears the bit.</p>	RW	0x0

3	RRDYEN	Receive Buffer Threshold wake-up enable bit. 0x0: Receive Buffer Threshold WK enable is NOT active 0x1: Receive Buffer Threshold WK enable is active	RW	0x0
2	REOFEN	Receive End Of Frame WK enable bit. 0x0: Receive End Of Frame WK enable is NOT active 0x1: Receive End Of Frame WK enable is active	RW	0x0
1	RFSREN	Receive Frame Synchronization WK enable bit. 0x0: Receive Frame Synchronization WK enable is NOT active 0x1: Receive Frame Synchronization WK enable is active	RW	0x0

Bits	Field Name	Description	Type	Reset
14	PPCONNECT	<p>Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output.</p> <p>0x0: non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit.</p> <p>0x1: Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.</p>	RW	0x0
13:12	DXENDLY	<p>When McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is set to one, this field selects the added delay as follow:</p> <p>0x0: 18 ns</p> <p>0x1: 26 ns (default)</p> <p>0x2: 35 ns</p> <p>0x3: 42 ns</p>	RW	0x1
11	XFULL_CYCLE	<p>Transmit full cycle mode select:</p> <p>0x0: McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data)</p> <p>0x1: McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data)</p>	RW	0x0
10:6	RESERVED	Read returns 0x0.	R	0x00
5	DLB	<p>Digital Loop-Back</p> <p>0x0: No DLB</p> <p>0x1: DLB</p>	RW	0x0
4	RESERVED	Read returns 0x0.	R	0x0
3	XDMAEN	<p>Transmit DMA Enable bit. When set to zero this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset.</p> <p>0x0: When set to zero this bit will gate the external transmit DMA request,</p> <p>0x1: When set to one this bit will NOT gate the external transmit DMA request,</p>	RW	0x1
2:1	RESERVED	Read returns 0x0.	R	0x0
0	XDISABLE	<p>Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary.</p> <p>0x0: The transmit process will NOT stop at the next frame boundary.</p> <p>0x1: The transmit process will stop at the next frame boundary.</p>	RW	0x0

## **MMC/SD/SDIO Card Interface**

---

---

---

This chapter describes the features and functions of the multimedia card/SD/SD I/O (MMC/SDIO) card interface for the OMAP34xx device.

<b>Topic</b>	<b>Page</b>
<b>22.1 MMC/SD/SDIO Overview .....</b>	<b>3027</b>
<b>22.2 MMC/SD/SDIO Environment .....</b>	<b>3031</b>
<b>22.3 MMC/SD/SDIO Integration .....</b>	<b>3039</b>
<b>22.4 MMC/SD/SDIO Functional Description .....</b>	<b>3047</b>
<b>22.5 MMC/SD/SDIO Basic Programming Model.....</b>	<b>3056</b>
<b>22.6 MMC/SD/SDIO Use Cases and Tips .....</b>	<b>3071</b>
<b>22.7 MMC/SD/SDIO Register Manual .....</b>	<b>3085</b>

## 22.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SD I/O (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

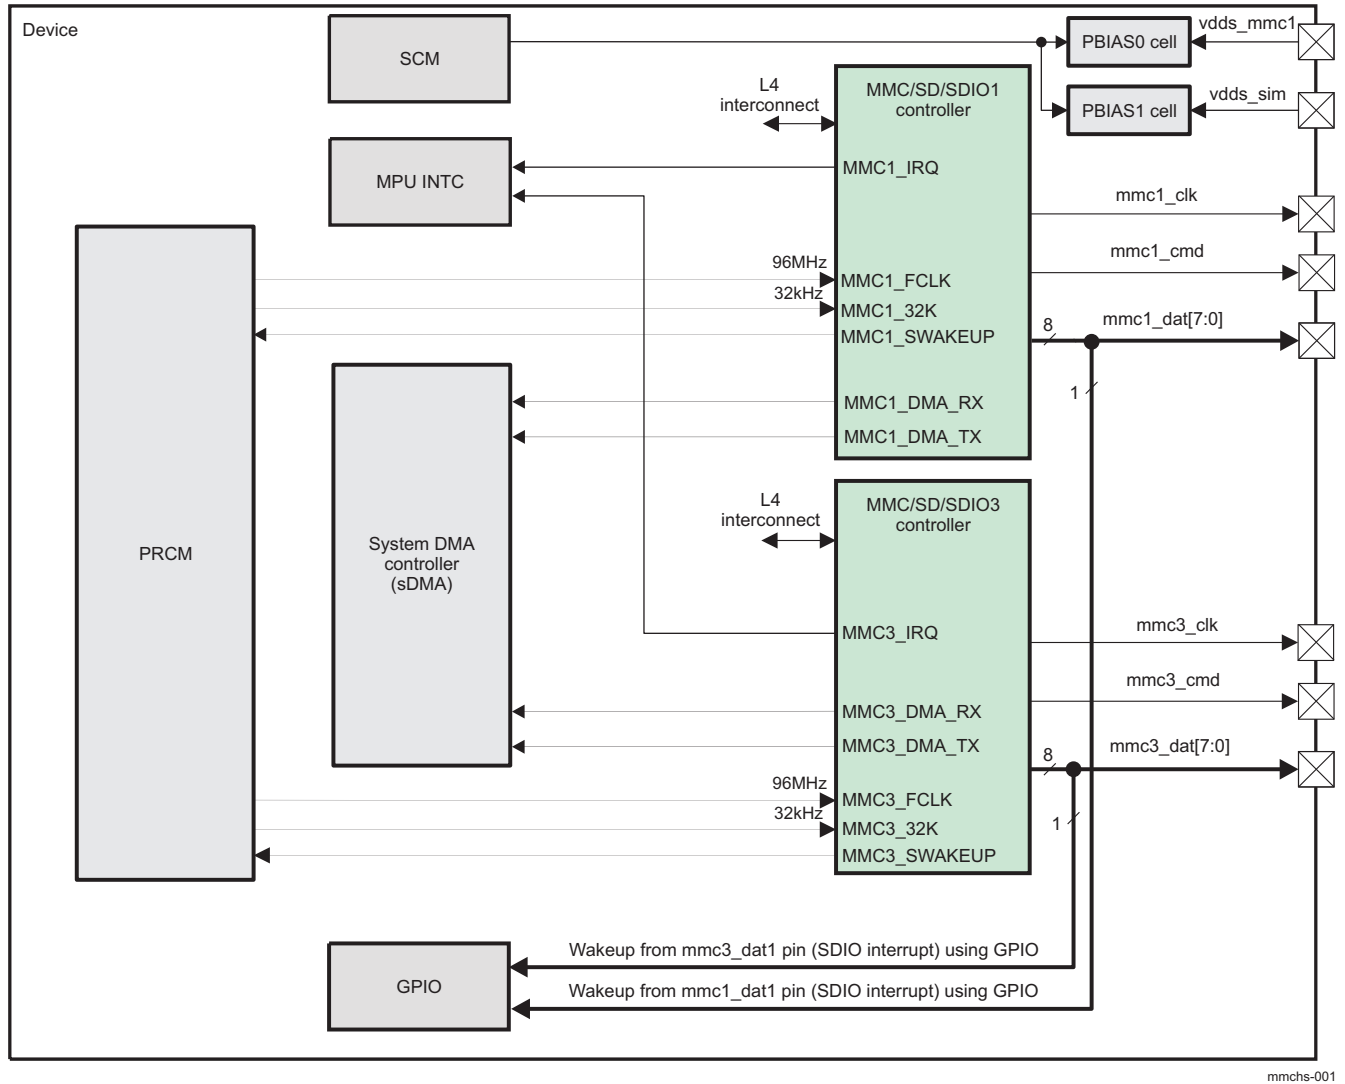

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

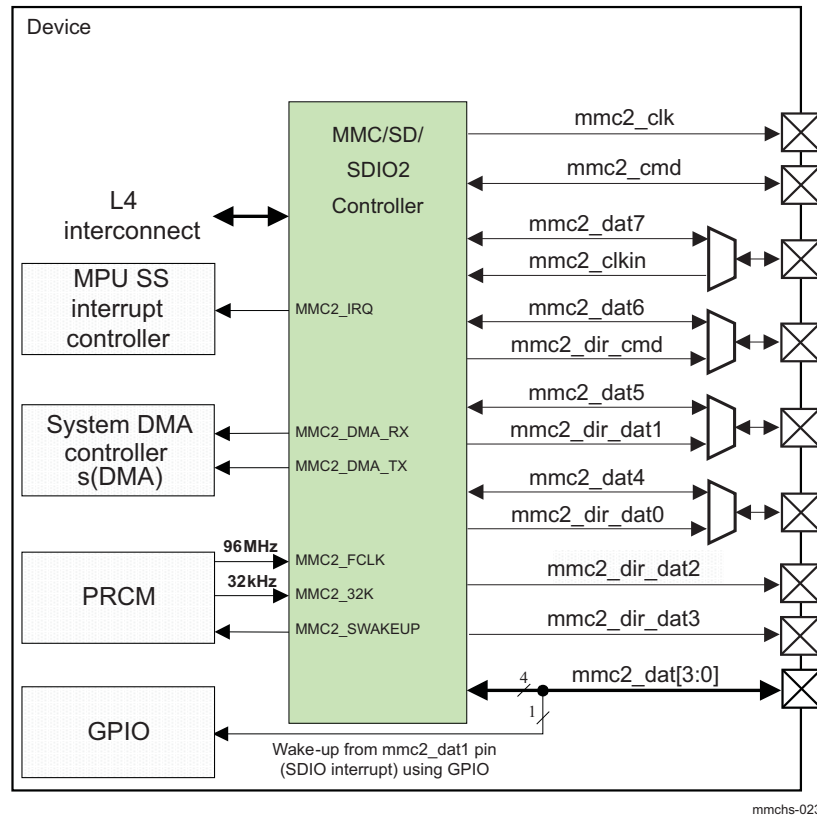

There are three MMC/SD/SDIO host controllers inside the device: [Figure 22-1](#) gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and [Figure 22-2](#) gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 22-1. MMC/SD/SDIO1 and 3 Overview

mmchs-001

Figure 22-2. MMC/SD/SDIO2 Overview

### 22.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.2 including high-capacity (size > 2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0 including high-capacity SDHC cards up to 32 GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v1.10
- Compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
  - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
  - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)
- Designed for low power

- Programmable clock generation
- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

The differences between the MMC/SD/SDIO host controllers and a Standard SD host controller are defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. Standard SD host controller is defined as DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy timeout.

## 22.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

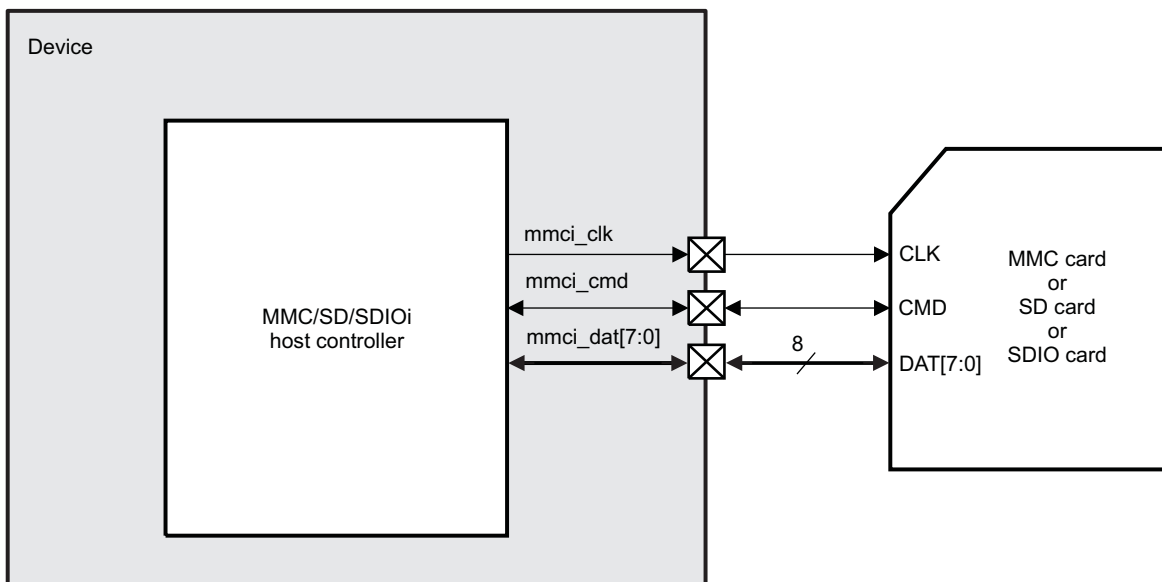

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver.

### 22.2.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 22-3 shows MMC/SD/SDIOi host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

**Figure 22-3. MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Without External Transceiver**

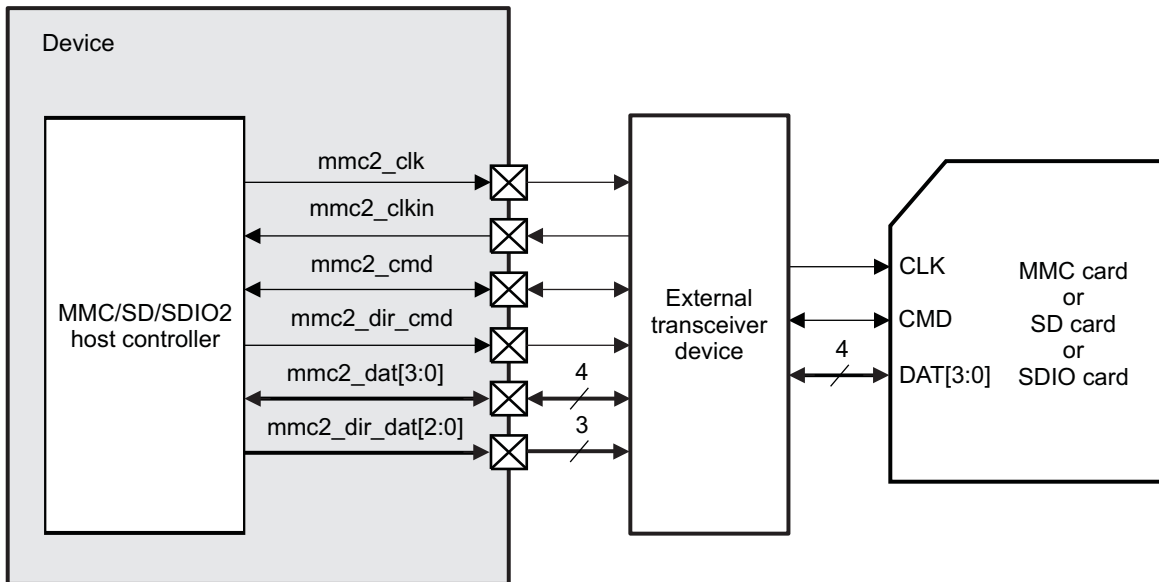

mmchs-002

### 22.2.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 22-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 22-4. MMC/SD/SDIO2 Connected to an MMC, an SD, or an SDIO Card with External Transceiver

mmchs-003

### 22.2.3 MMC/SD/SDIO Functional Interfaces

#### 22.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 22-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 22-5. MMC/SD/SDIOi Interface Signals

mmchs-004

Table 22-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 22-1. MMC/SD/SDIOi I/O Description

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
mmci_clk	O	External clock for MMC/SD/SDIO card <sup>(2)</sup>	0
mmci_cmd	I/O	Command signal	0
mmci_dat[7:0]	I/O	Data signals	0

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> This output signal is also used as re-timing input.

### 22.2.3.2 Basic MMC/SD/SDIO2 Pins with External Transceiver

Figure 22-6 shows the MMC/SD/SDIO2 host controller interface signals.

**Figure 22-6. MMC/SD/SDIO2 Interface Signals**

Table 22-2 describes the MMC/SD/SDIO2 inputs/outputs.

**Table 22-2. MMC/SD/SDIO2 I/O Description**

Signal Name	I/O	Description	Reset Value
mmc2_clk	O	External clock for MMC/SD/SDIO card	0
mmc2_clkkin	I	Input clock from MMC/SD/SDIO card	0
mmc2_cmd	I/O	Command signal	0
mmc2_dir_cmd	O	Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive)	0
mmc2_dat[3:0]	I/O	Data signals	0
mmc2_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat1	O	Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat2	O	Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat3	O	Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmci_dat[7:4] are muxed with other direction control signals. See <a href="#">Chapter 7, System Control Module</a> for further details on the pin multiplexing.	0

### 22.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

**Command:** a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmci\_cmd line.

**Response:** a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmci\_cmd line.

**Data:** data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

**Busy:** the mmci\_dat0 signal is maintained low by the card as far as it is programming the data received.

**CRC status:** CRC result is sent by the card through the mmci\_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci\_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci\_dat0 and starts the data programming procedure.

**22.2.3.3.1 Protocol**

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

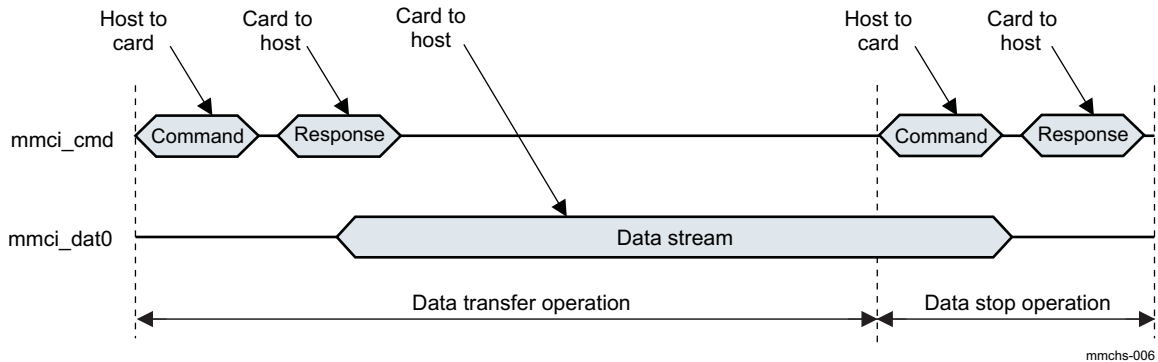

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, and the *SDIO Card Specification, Part E1, August 2004*, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 22-7 and Figure 22-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci\_cmd line.

**CAUTION**  
Stream commands are supported only by MMC cards.

**Figure 22-7. Sequential Read Operation (MMC Cards Only)**

**Figure 22-8. Sequential Write Operation (MMC Cards Only)**

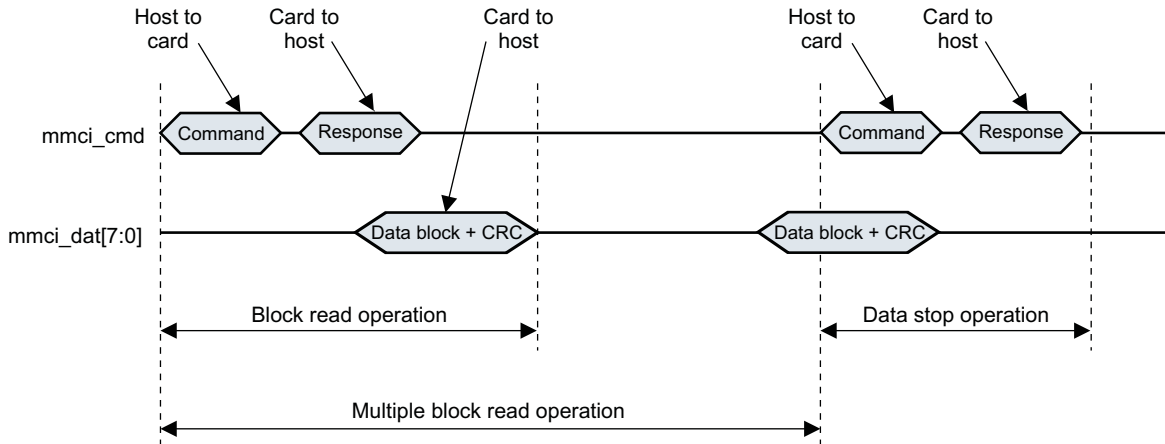

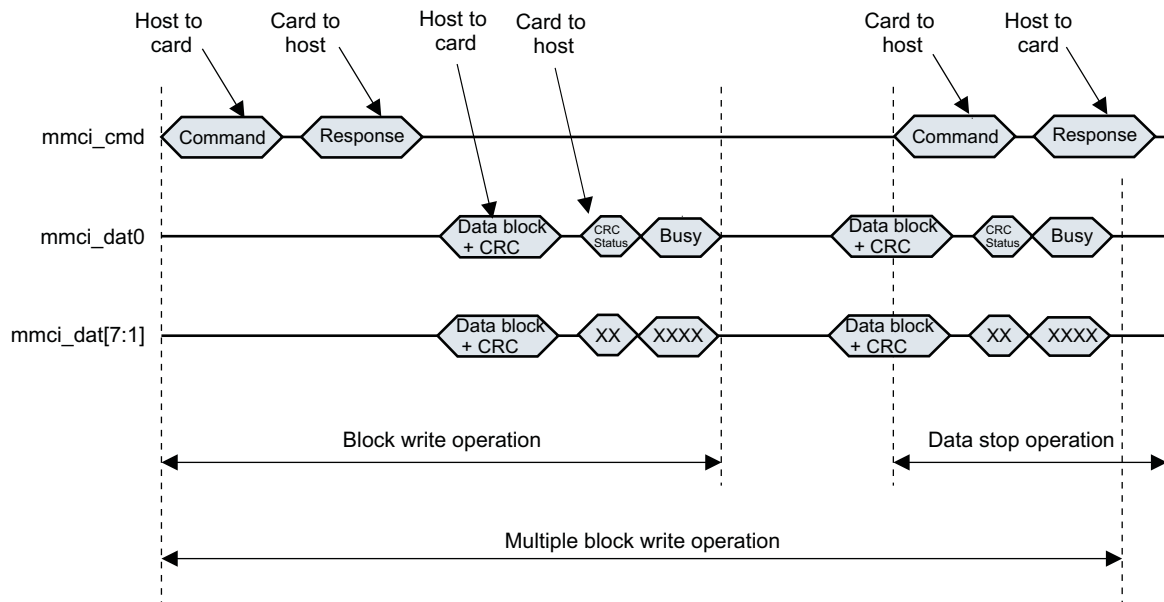

Figure 22-9 and Figure 22-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci\_cmd line. These operations are available for all kinds of cards.

**Figure 22-9. Multiple Block Read Operation**

mmchs-008

**Figure 22-10. Multiple Block Write Operation with Card Busy Signal**

mmchs-009

**Notes:**

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set `MMCI_MMCHS_SYSCCTL[26]` SRD bit to 0x1) after data timeout to ensure `mmci_clk` is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a `CMD23` before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

**22.2.3.3.2 Data Format**

**Coding Scheme for Command Token**

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 22-11](#)).

**Figure 22-11. Command Token Format**

**Coding Scheme for Response Token**

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 22-12](#) and [Figure 22-13](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 22-3](#)). For more details about response types, see the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, or the *SDIO Card Specification, Part E1*, v1.10.

**Figure 22-12. Response Token Format (R1, R3, R4, R5, R6)**

**Figure 22-13. Response Token Format (R2)**

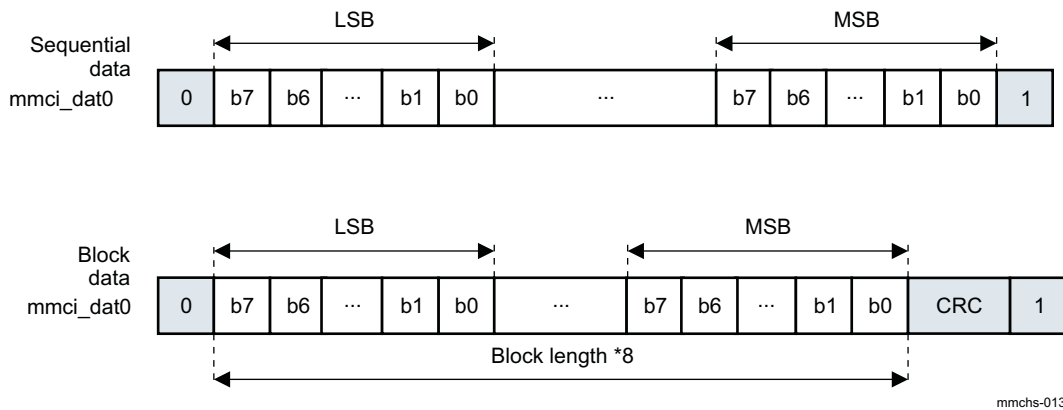

**Table 22-3. Relation Between Configuration and Name of Response Type<sup>(1)</sup>**

Response Type MMCI.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCI.MMCHS_CMD[20] CICE	CRC Check Enable MMCI.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5
11	1	1	R1b, R5b

<sup>(1)</sup> The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit.

### Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 22-14](#), [Figure 22-15](#), and [Figure 22-16](#)).

**Figure 22-14. Data Token Format for 1-Bit Transfers****Figure 22-15. Data Token Format for 4-Bit Transfers**

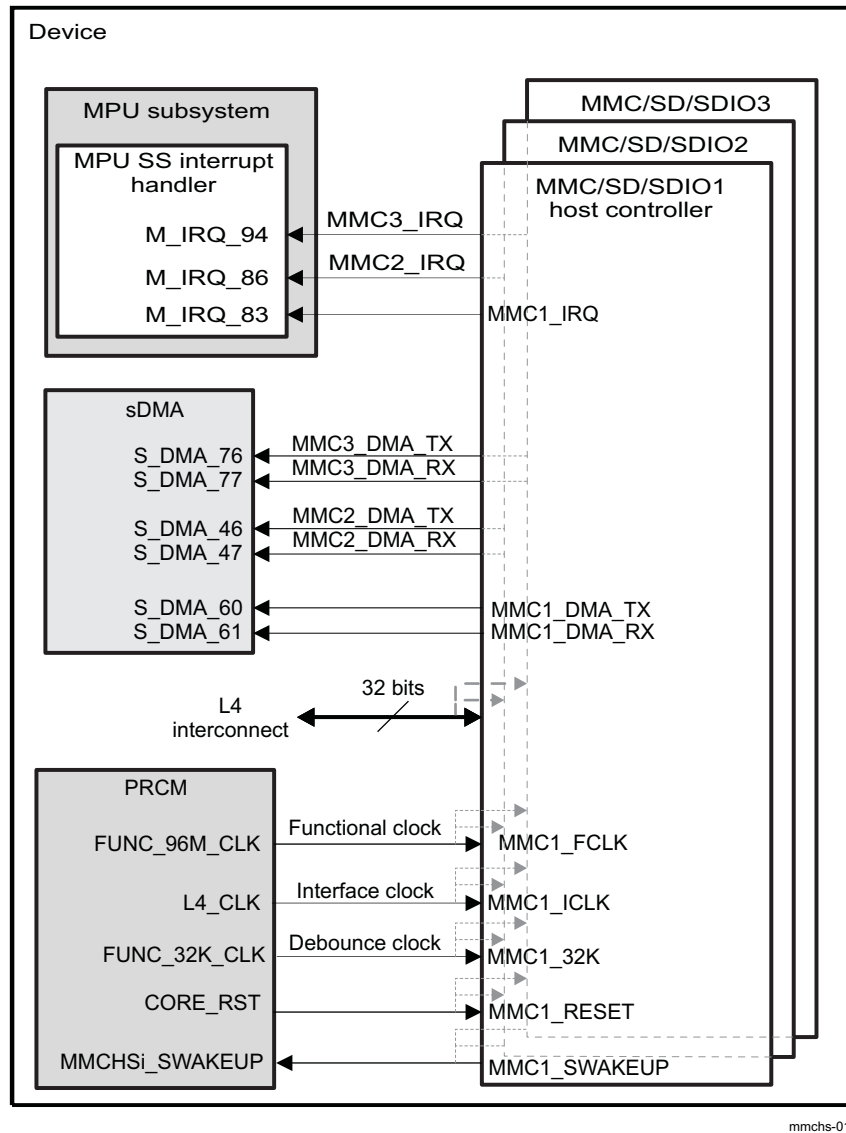

## 22.3 MMC/SD/SDIO Integration

Figure 22-17 shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 22-17. MMC/SD/SDIO1 Integration

### 22.3.1 Clocking, Reset, and Power-Management Scheme

#### 22.3.1.1 Clocks

##### 22.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMC<sub>i</sub>\_FCLK) independent of the device external clock frequency
- An interface clock (the MMC<sub>i</sub>\_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMC<sub>i</sub>\_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see [Chapter 4, Power Reset and Clock Management](#) for more information).

### 22.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

#### Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS\_SYSCONFIG[0] AUTOIDLE bit is set to 1 (I = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCI\_ICLK clock autogated) even if MMCI.MMCHS\_SYSCONFIG[0] AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

#### Idle Mode

The MMCI\_ICLK and MMCI\_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCI\_ICLK and MMCI\_FCLK clocks may be switched off whatever the value set in the MMCI.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY field.

#### Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCI\_ICLK clock is alive. The PRCM.CM\_IDLEST1\_CORE[25] ST\_MMC2 and (respectively the PRCM.CM\_IDLEST1\_CORE[24] ST\_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on mmci\_dat[1] signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

### Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- MMCI.MMCHS\_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1
- MMCI.MMCHS\_HCTL[24] IWE bit is set to 0x1
- MMCI.MMCHS\_IE[8] CIRQ\_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 22-4 lists the supported cases in smart-idle mode.

**Table 22-4. Smart Idle Mode and Wake-Up Capabilities**

Mode	MMCI_ICLK clock	MMCI_FCLK clock	Wake-up Event
Card interrupt	May be switched off <sup>(1)</sup>	May be switched off <sup>(1)</sup>	The module sends an asynchronous wake-up request on detection of a card interrupt on mmci_dat[1] signal

<sup>(1)</sup> The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit.

### Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS\_STAT register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCI.MMCHS\_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCI.MMCHS\_HCTL and MMCI.MMCHS\_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS\_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCI.MMCHS\_IE[8] CIRQ\_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS\_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

### Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS\_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi\_ICLK and MMCi\_FCLK can be switched off.

#### **CAUTION**

In force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi\_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

### **22.3.1.2 Resets**

#### **22.3.1.2.1 Hardware Reset**

The module is reinitialized by the hardware when the active-low reset signal (CORE\_RST), synchronous to the MMCi\_ICLK clock is asserted on the input pin MMCi\_RESET (see [Chapter 4, Power, Reset, and Clock Management](#) for more information).

A global status bit RESETDONE is provided in the status register MMCi.MMCHS\_SYSSTATUS[0]. This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCi.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

---

**Note:** Functional clock MMCi\_FCLK, interface clock MMCi\_ICLK, and debounce clock MMCi\_32K must be provided to the module to allow the RESETDONE status bit to be set.

---

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

#### **22.3.1.2.2 Software Reset**

The module is reinitialized by software through the MMCi.MMCHS\_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCi\_RESET signal except for:

- Debounce logic
- MMCi.MMCHS\_PSTATE, MMCi.MMCHS\_CAPA, and MMCi.MMCHS\_CUR\_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCi.MMCHS\_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCi.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS\_SYSCTL[26] SRD bit
- MMCi.MMCHS\_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCI.MMCHS\_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The MMCI.MMCHS\_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

### 22.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see [Chapter 4, Power Reset and Clock Management](#) for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci\_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see [Chapter 25, General-Purpose Interface](#), for more information).

## 22.3.2 Hardware Requests

### 22.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v1.00*.

The DMA request is issued if the three following conditions are met:

- The MMCI.MMCHS\_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci\_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S\_DMA\_60 (MMC1\_DMA\_TX)
- S\_DMA\_61 (MMC1\_DMA\_RX)
- S\_DMA\_46 (MMC2\_DMA\_TX)
- S\_DMA\_47 (MMC2\_DMA\_RX)
- S\_DMA\_76 (MMC3\_DMA\_TX)
- S\_DMA\_77 (MMC3\_DMA\_RX)

#### 22.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI\_DMA\_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.MMCHS\_BLK[10:0] BLEN field.

The MMCI\_DMA\_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

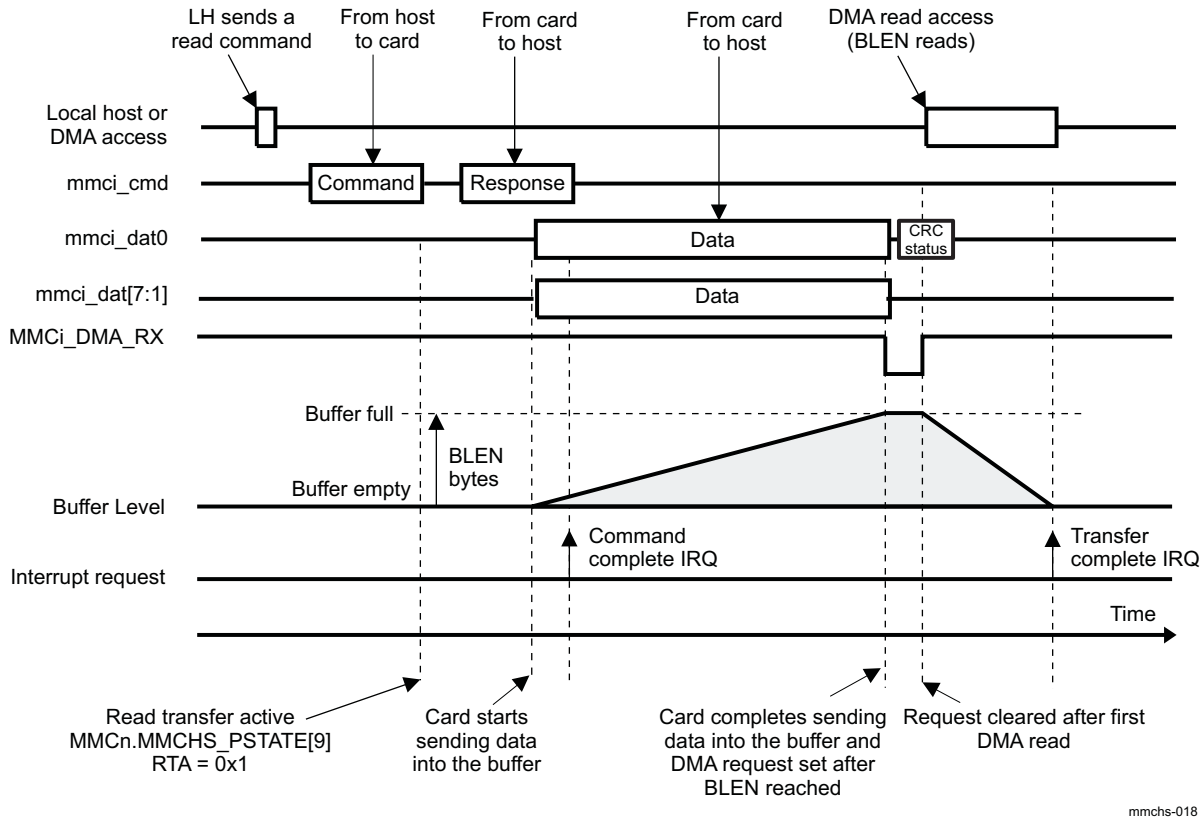

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is  $\text{Integer}(\text{BLEN}/4)+1$ .

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci\_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see [Figure 22-18](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 22-18. DMA Receive Mode

mmchs-018

### 22.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi\_DMA\_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS\_BLK[10:0] BLEN field.

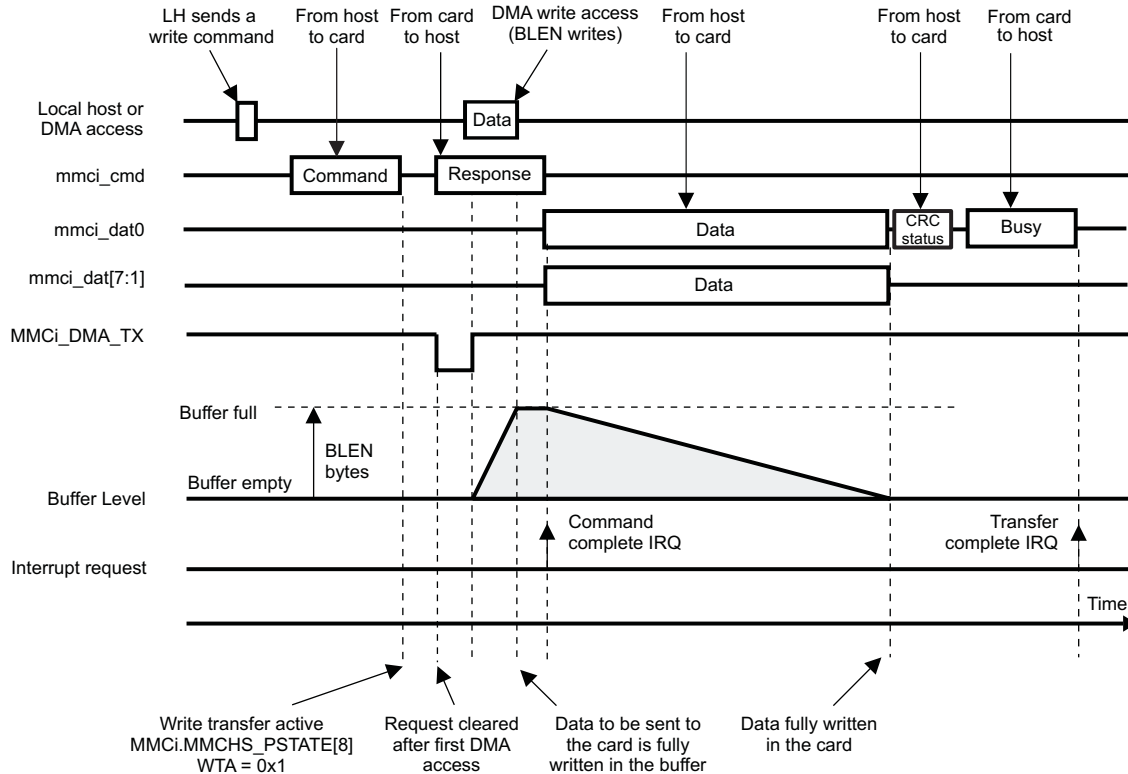

The MMCi\_DMA\_TX signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is  $\text{Integer}(\text{BLEN}/4)+1$ ) and if there is not enough memory space to write a complete block in the buffer.

Summary (see Figure 22-19):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

**Figure 22-19. DMA Transmit Mode**

### 22.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the `MMCi.MMCHS_STAT` register; it indicates which service is required.
- The interrupt status enable bits of the `MMCi.MMCHS_IE` register enable/disable the automatic update of the `MMCi.MMCHS_STAT` register on an event-by-event basis.
- The interrupt signal enable bits of the `MMCi.MMCHS_ISE` register enable/disable the transmission of an interrupt request on the interrupt line `MMCi_IRQ` (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the `MMCi.MMCHS_IE` register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the `MMCi.MMCHS_ISE` register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the `MMCi.MMCHS_STAT` register. If later a mask is applied on the interrupt in the `MMCi.MMCHS_ISE` register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the `MMCi.MMCHS_STAT` register and the corresponding mask is removed from the `MMCi.MMCHS_ISE` register, the interrupt status is not asserted again in the `MMCi.MMCHS_STAT` register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

### CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCi.MMCHS\_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCi.MMCHS\_STAT or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1\_IRQ is connected to M\_IRQ\_83 for MMC/SD/SDIO1 instance.
- MMC2\_IRQ is connected to M\_IRQ\_86 for MMC/SD/SDIO2 instance.
- MMC3\_IRQ is connected to M\_IRQ\_94 for MMC/SD/SDIO3 instance.

#### 22.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.MMCHS\_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCi.MMCHS\_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCi.MMCHS\_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

---

**Note:** In the MMCi.MMCHS\_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.  
The MMCi.MMCHS\_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS\_IE[8] CIRQ\_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See [Chapter 5, Interconnect](#) for more information.  
The MMCi.MMCHS\_STAT[15] ERRI bit is automatically cleared when all status bits in MMCi.MMCHS\_STAT[31:16] are cleared.

---

#### 22.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS\_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS\_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS\_STAT register clears the interrupt status and does not affect the interrupt line state.

---

**Note:** Refer to the previous note concerning CIRQ and ERRI bits clearing.

---

## 22.4 MMC/SD/SDIO Functional Description

### 22.4.1 Description

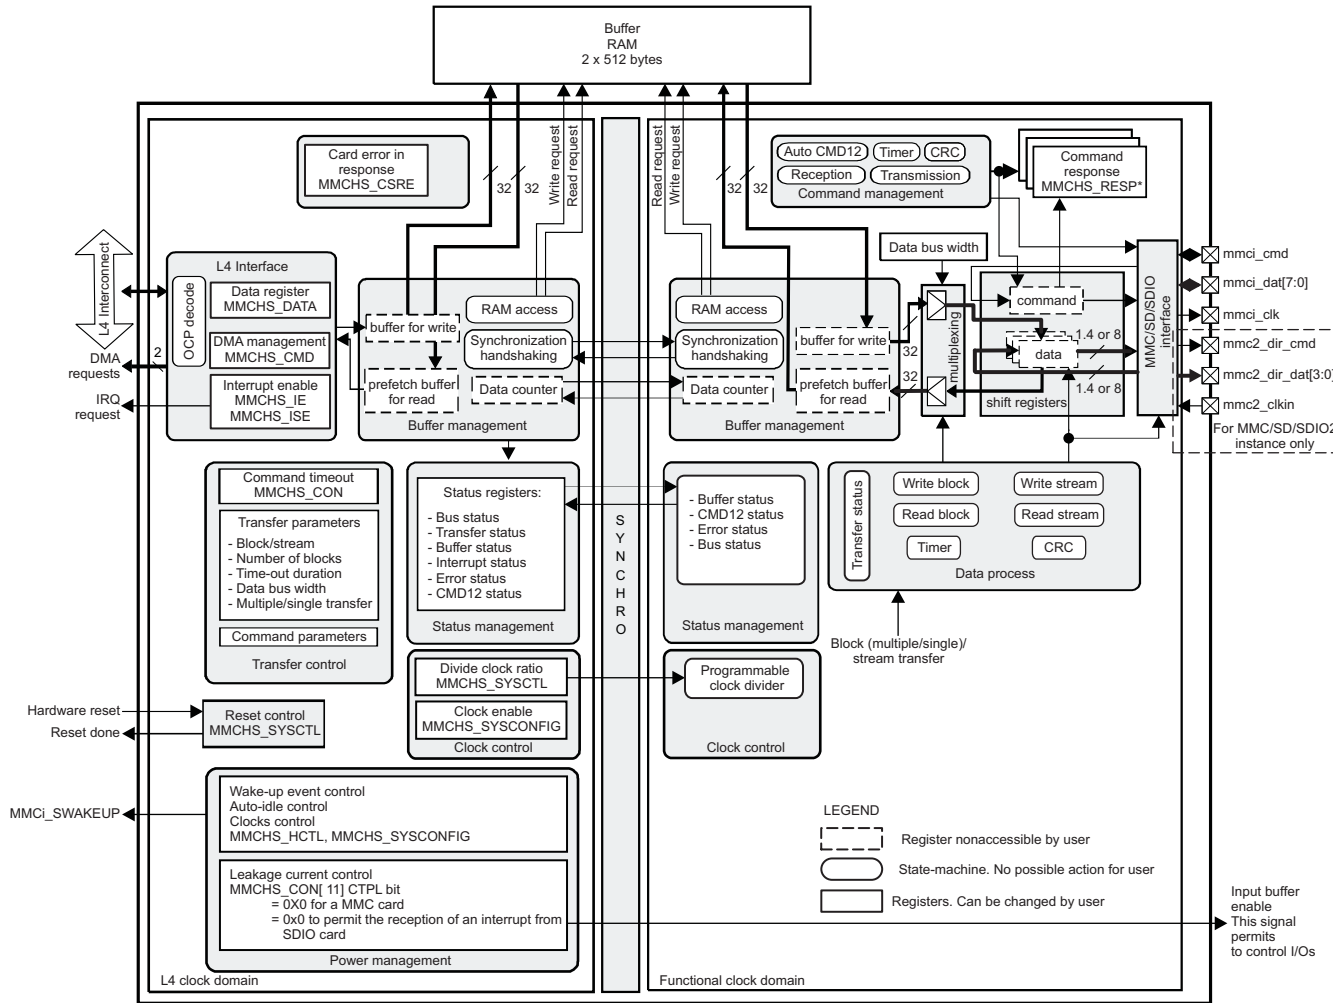

MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2\*512 RAM).

[Figure 22-20](#) shows a block diagram of the MMC/SD/SDIO host controller.

Figure 22-20. MMC/SD/SDIO Diagram

mmchs-020

In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests
- Consult different status:

- Bus
- Buffer
- Interrupts
- Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS\_RSPn registers: [Table 22-52](#), [Table 22-54](#), [Table 22-56](#), and [Table 22-58](#)).

**CAUTION**

Read access to the command response registers is allowed only when the command process is completed.

## 22.4.2 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, and the *SDIO Card Specification, Part E1, v1.10*, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

## 22.4.3 Buffer Management

### 22.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register `MMCi.MMCHS_DATA`. A write access to the `MMCi.MMCHS_DATA` register followed by a read access from the `MMCi.MMCHS_DATA` register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the `MMCi.MMCHS_DATA` register and the data of the read access to the `MMCi.MMCHS_DATA` register are different.

The number of 32-bit accesses to the `MMCi.MMCHS_DATA` register that are needed to read (or write) a data block with a size of `MMCi.MMCHS_BLK[10:0] BLEN`, and equals the rounded up result of `BLEN` divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register `MMCi.MMCHS_CAPA[17:16] MBL` field and cannot be changed.

A read access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer read enable status is set to 1 (`MMCi.MMCHS_PSTATE[11] BRE`); otherwise, a bad access (`MMCi.MMCHS_STAT[29] BADA`) is signaled.

A write access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer write enable status is set to 1 (`MMCi.MMCHS_PSTATE[10] BWE`); otherwise, a bad access (`MMCi.MMCHS_STAT[29] BADA`) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in `BLEN` is less than or equal to `0x200`, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When `BLEN` is less than,

or equal to 0x200 (that is, less than, or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits x BLEN div by 4). Do not use a size greater than 2 times this value.

**CAUTION**

The MMCi.MMCHS\_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

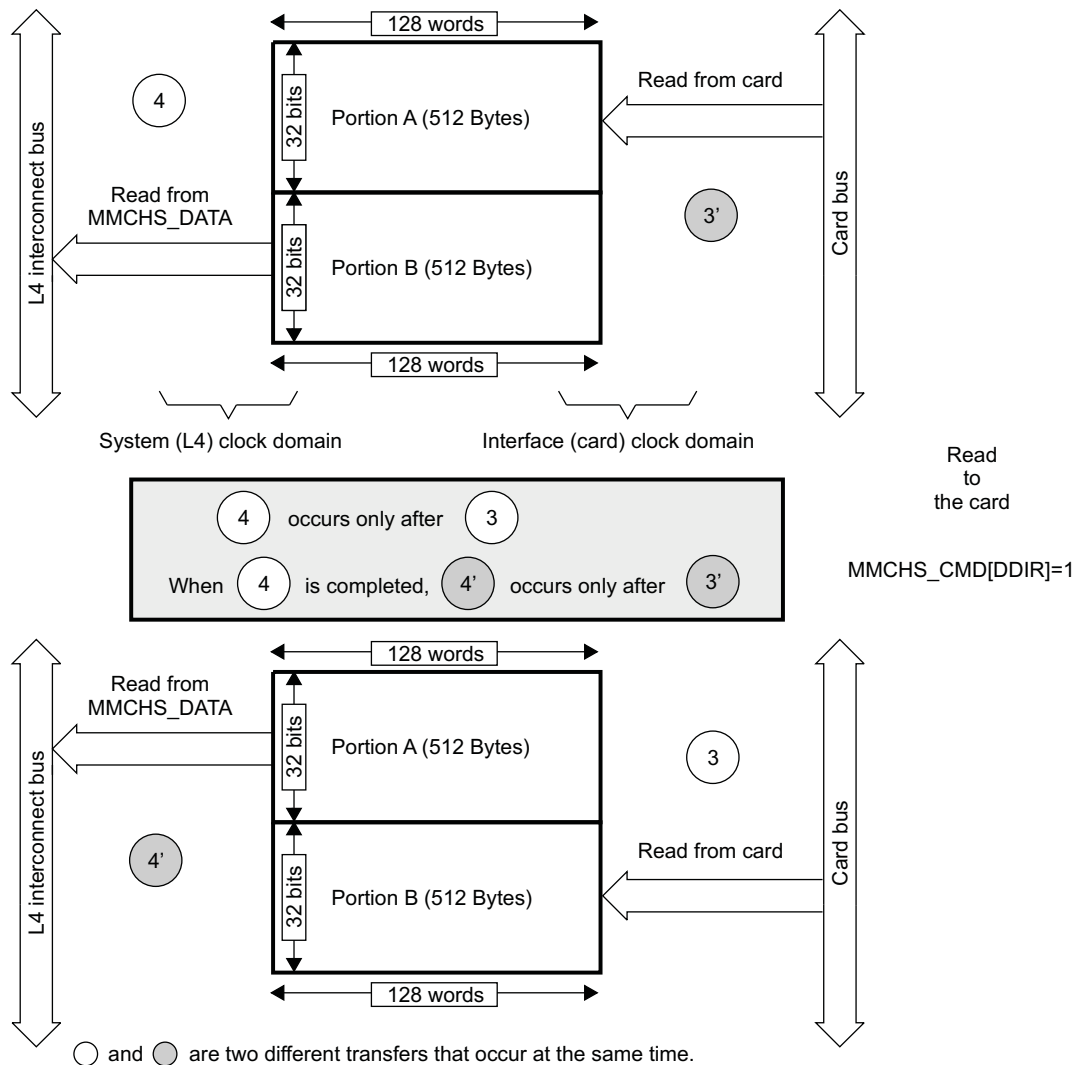

Figure 22-21 and Figure 22-22 show the buffer management for a write and for a read, respectively.

**Figure 22-21. Buffer Management for a Write**

mmchs-047

Figure 22-22. Buffer Management for a Read

mmchs-043

- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS\_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

### 22.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Table 22-68):
  - MMCi.MMCHS\_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS\_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS\_STAT[4] BWR: Buffer write ready
- Status registers (see Table 22-62):
  - MMCi.MMCHS\_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS\_PSTATE[10] BWE: Buffer write enable

## 22.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

### 22.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

### 22.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

Table 22-5 shows how the MMC, SD, and SDIO responses are stored in the MMCHS\_RSPxx registers.

**Table 22-5. MMC, SD, SDIO responses in the MMCHS\_RSPxx registers**

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP76[31:0]
R2	RESP[127:0] <sup>(1)</sup>	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

<sup>(1)</sup> RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS\_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS\_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS\_RSP10 register and vice versa.

## 22.4.5 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 22-6 and register description for more details.

**Table 22-6. CC and TC Values Upon Error Detected**

Error hold in the MMCh.MMCHS_STAT register	CC	TC	Comments
29 BADA			No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.

**Table 22-6. CC and TC Values Upon Error Detected (continued)**

Error hold in the MMCI.MMCHS_STAT register		CC	TC	Comments
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC - See CTO comment
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears.

### 22.4.6 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

---

**Note:** Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

---

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).  
This feature is enabled by setting the MMCI.MMCHS\_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.
- Stop at block gap  
This feature is enabled by setting the MMCI.MMCHS\_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

---

**Note:** For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

---

Table 22-7 shows the common way to stop a transfer, indicating command to send and features to enable.

**Table 22-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary**

		WRITE transfer		READ transfer	
		SD / MMC	SDIO	SD / MMC	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCI.MMCHS_HC TL[16] SBGR bit to 0x1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	<b>If READ_WAIT supported</b> Stop at block gap Wait TC <hr/> <b>If READ_WAIT not supported</b> Send CMD52 Wait TC

**Note:** The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

#### 22.4.7 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal ([MMCHS\\_CON\[12\]](#) CEATA and [MMCHS\\_CMD\[2\]](#) ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- [MMCHS\\_CON\[12\]](#) CEATA is set to 1.
- [MMCHS\\_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS\\_ARG](#) register.
- Write into [MMCHS\\_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, [MMCHS\\_STAT\[0\]](#) CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

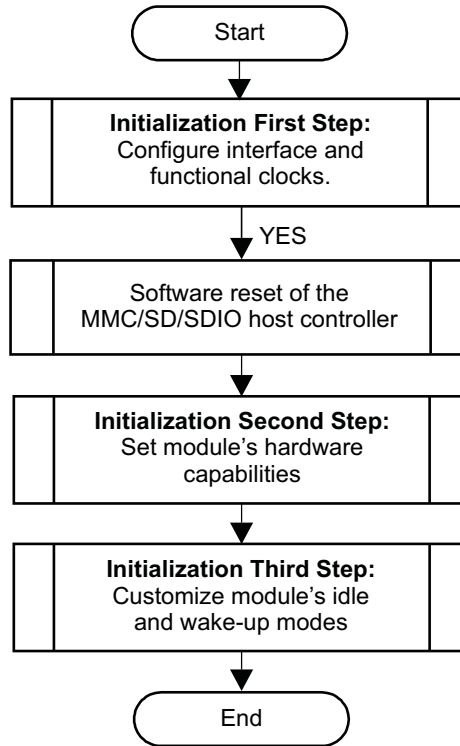

- CCS is receive just before CCSD is emitted:  
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:  
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:  
Only the interrupt CIRQ is generated when CCS is detected.

## 22.5 MMC/SD/SDIO Basic Programming Model

### 22.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 22-23 shows the general boot process.

**Figure 22-23. MMC/SD/SDIO Controller Meta Initialization Steps**

mmchs-024

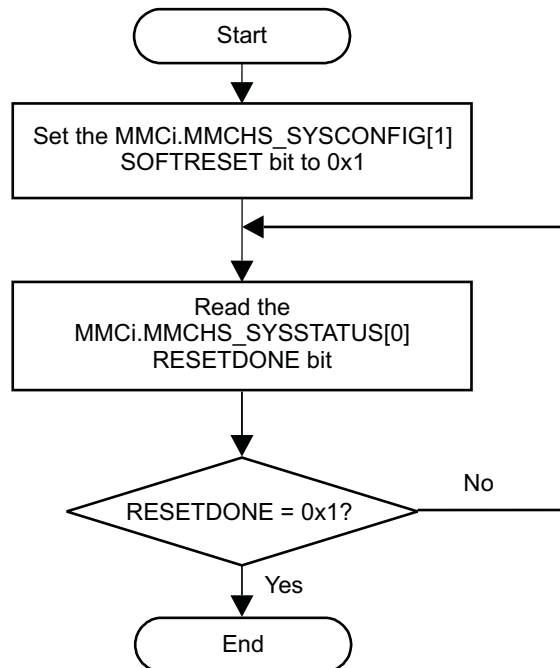

#### 22.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM\_ICLKEN1\_CORE and PRCM.CM\_FCLKEN1\_CORE. Please refer to [Chapter 4, Power, Reset, and Clock Management](#).

### 22.5.1.2 MMCHS Soft Reset Flow

Figure 22-24 shows the soft reset process of MMCHS controller.

**Figure 22-24. MMC/SD/SDIO Controller Software Reset Flow**

mmchs-025

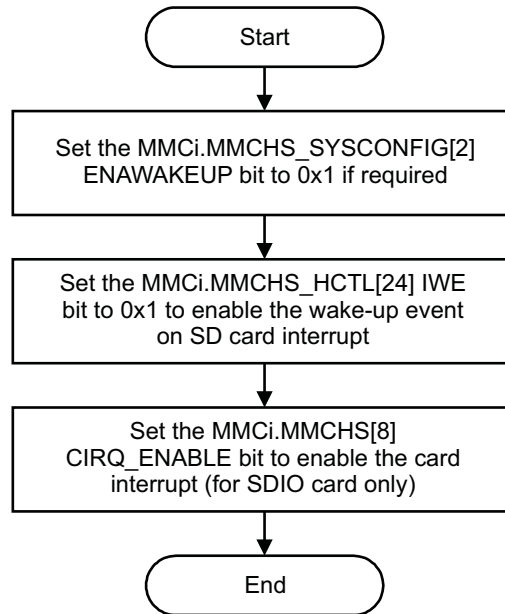

### 22.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) MMCi.MMCHS\_CAPA[26:24] and MMCi.MMCHS\_CUR\_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

### 22.5.1.4 Wake-Up Configuration

Figure 22-25 details MMCHS controller wake-up configuration.

**Figure 22-25. MMC/SD/SDIO Controller Wake-Up Configuration**

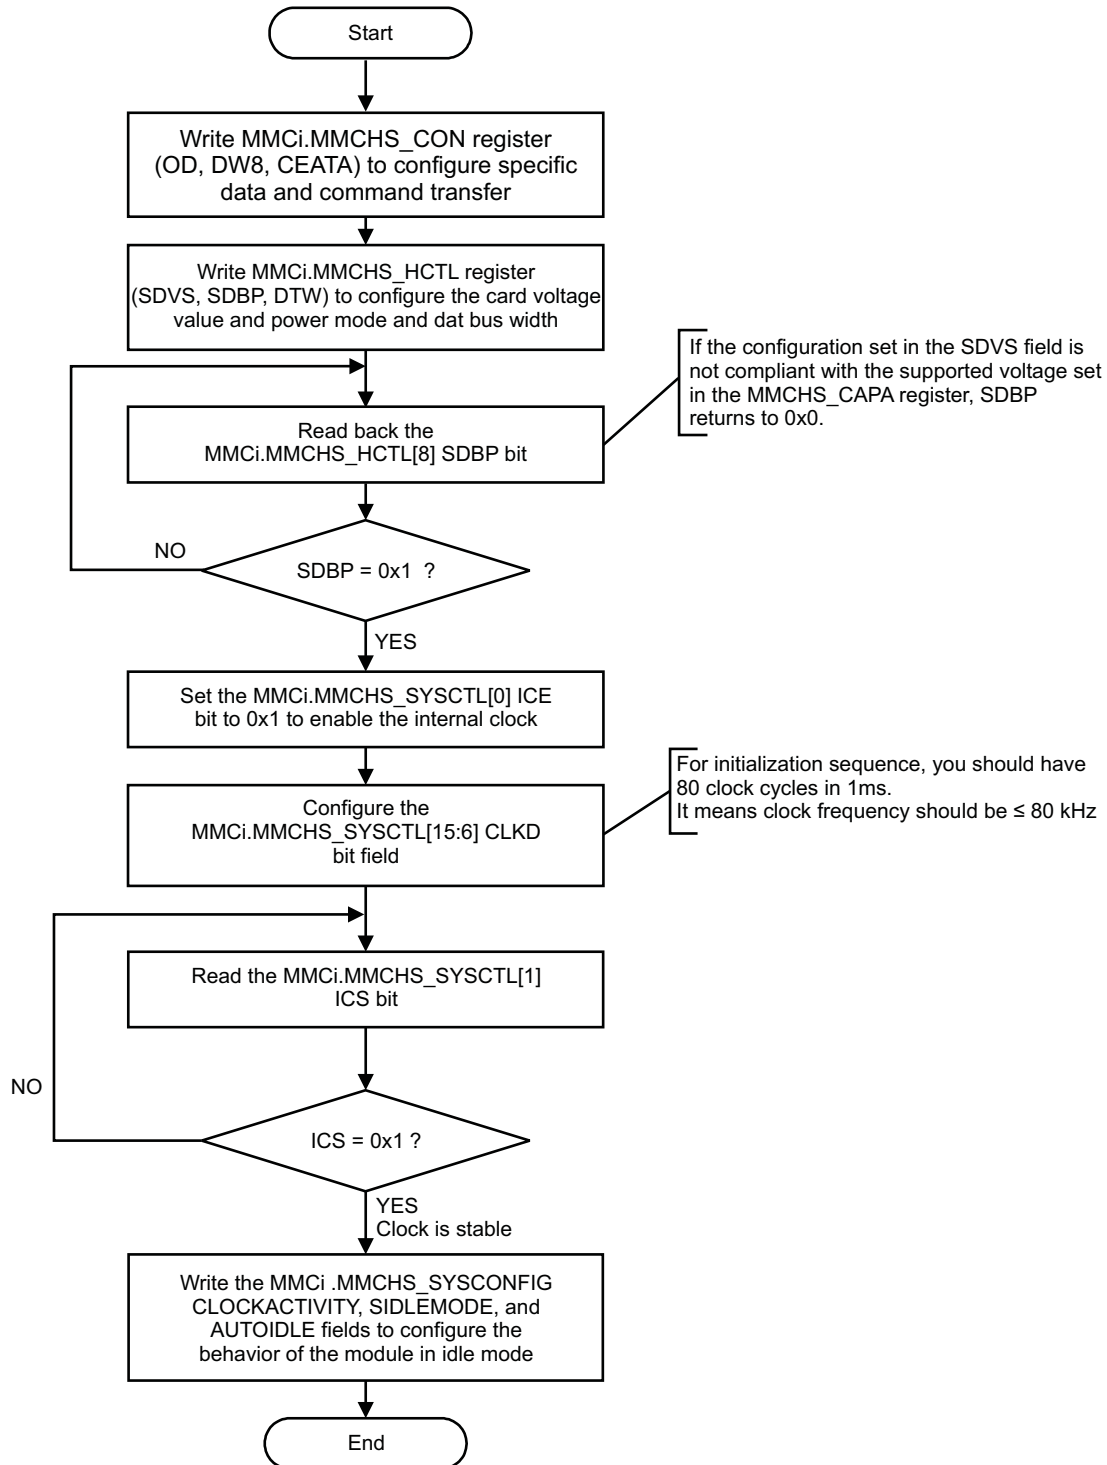

mmchs-027

### 22.5.1.5 MMC Host and Bus Configuration

Figure 22-26 details MMC bus configuration process.

**Figure 22-26. MMC/SD/SDIO Controller Bus Configuration**

mmchs-028

### 22.5.2 Basic Operations for MMC/SD/SDIO Host Controller

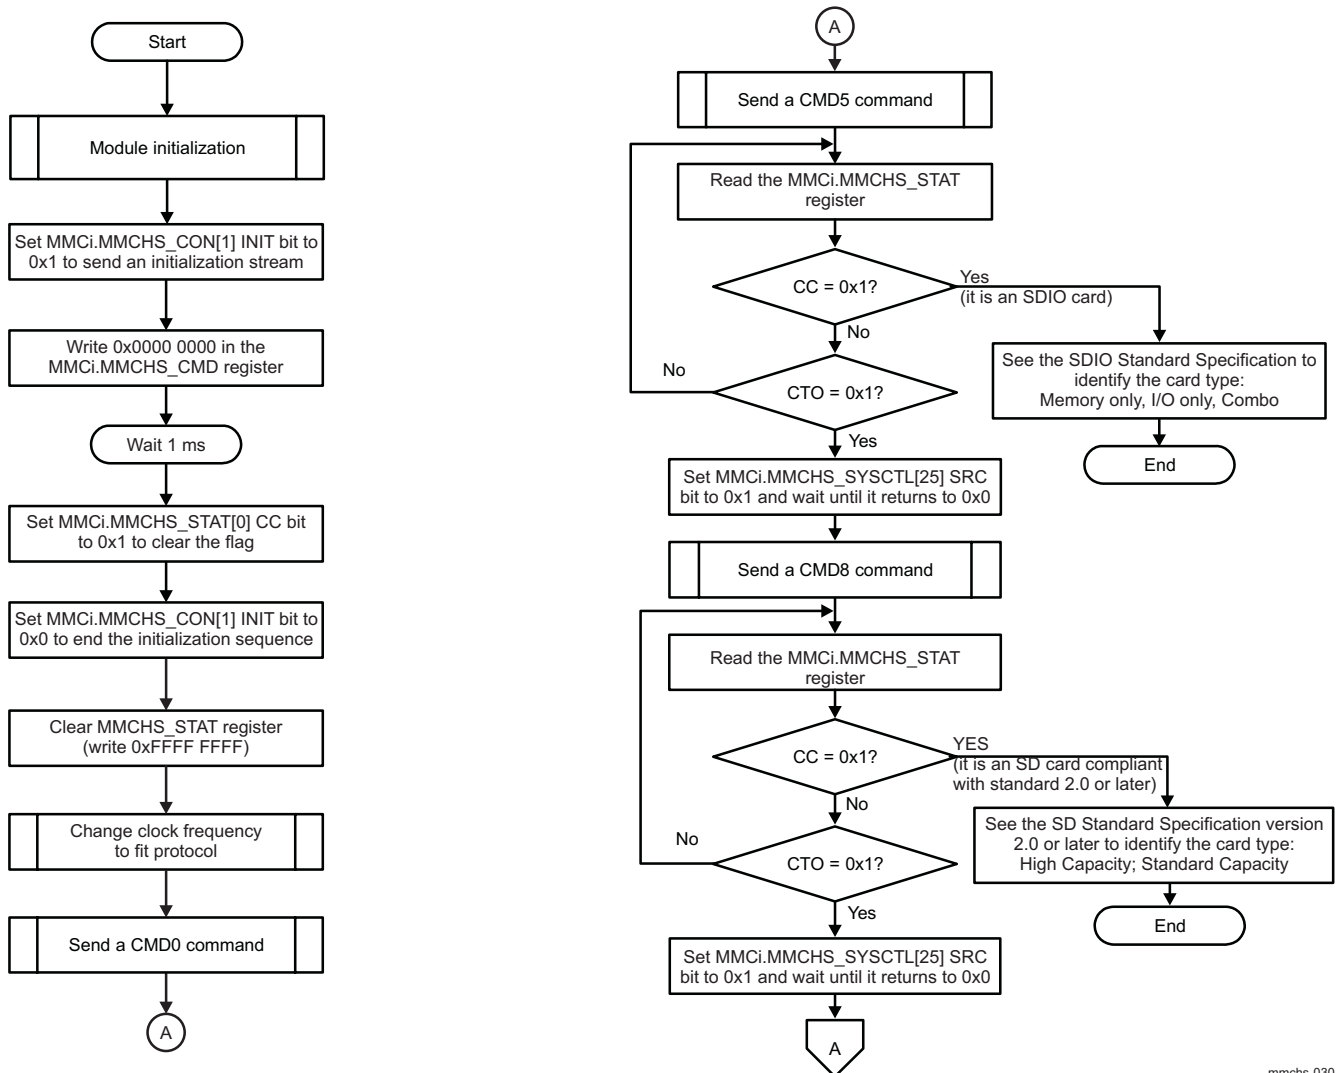

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

#### 22.5.2.1 Card Detection, Identification, and Selection

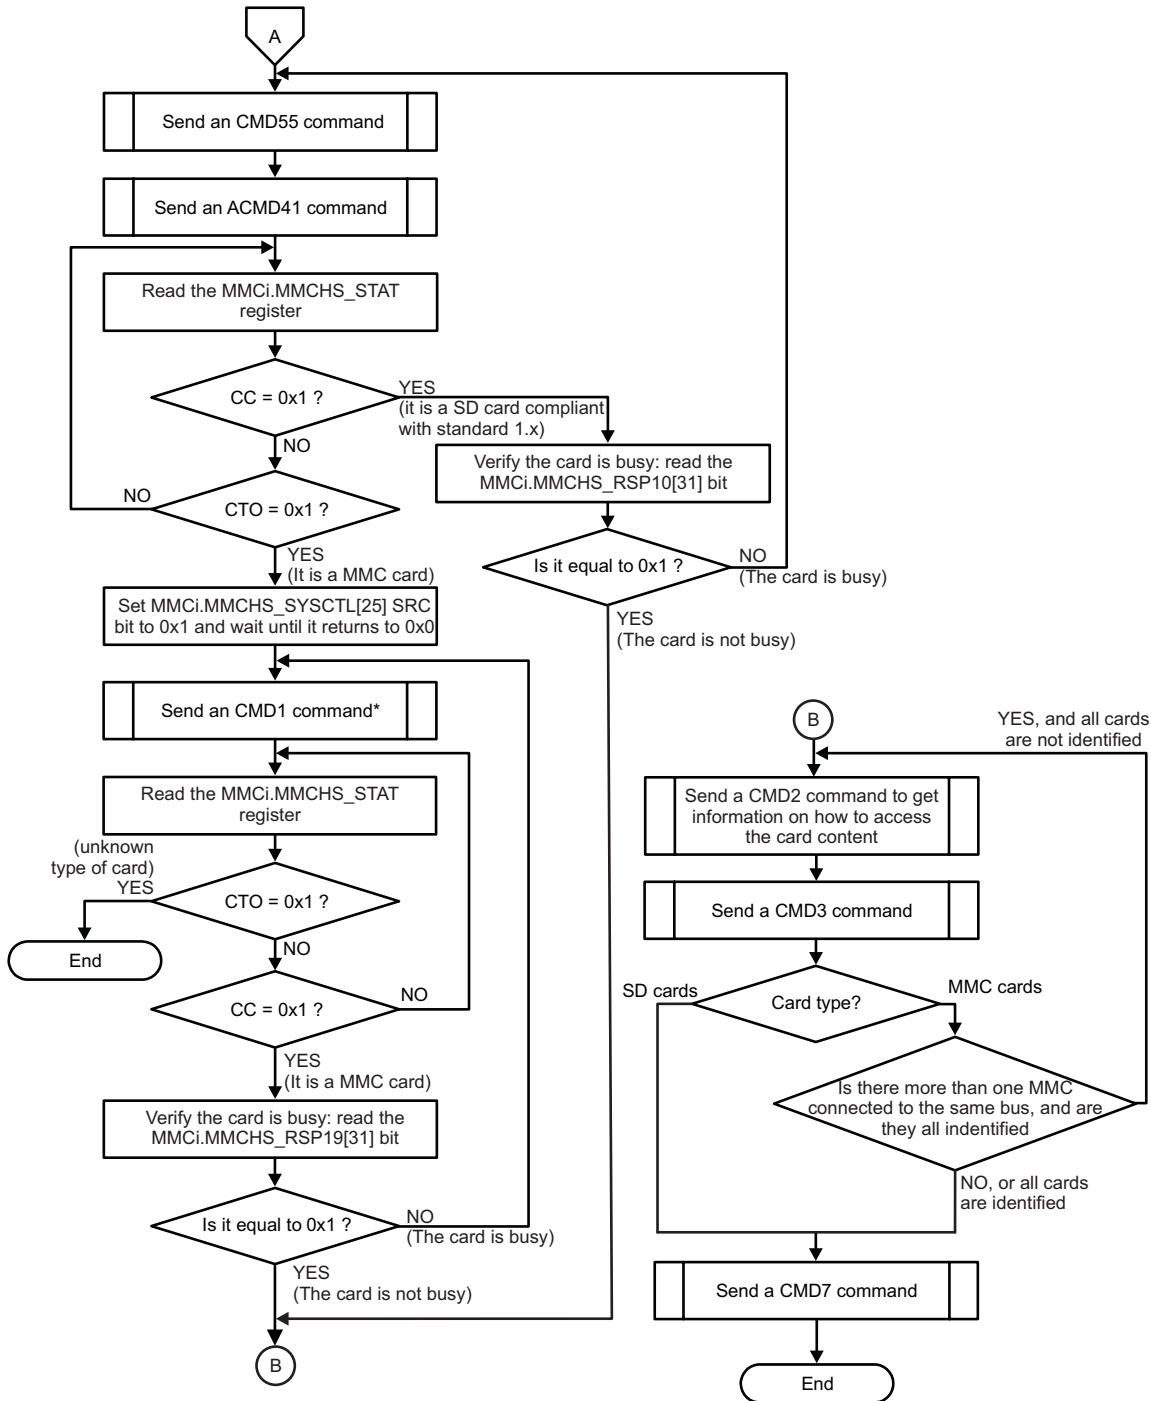

Figure 22-27 and Figure 22-28 show the card identification and selection process.

Figure 22-27. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

mmchs-030

Figure 22-28. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

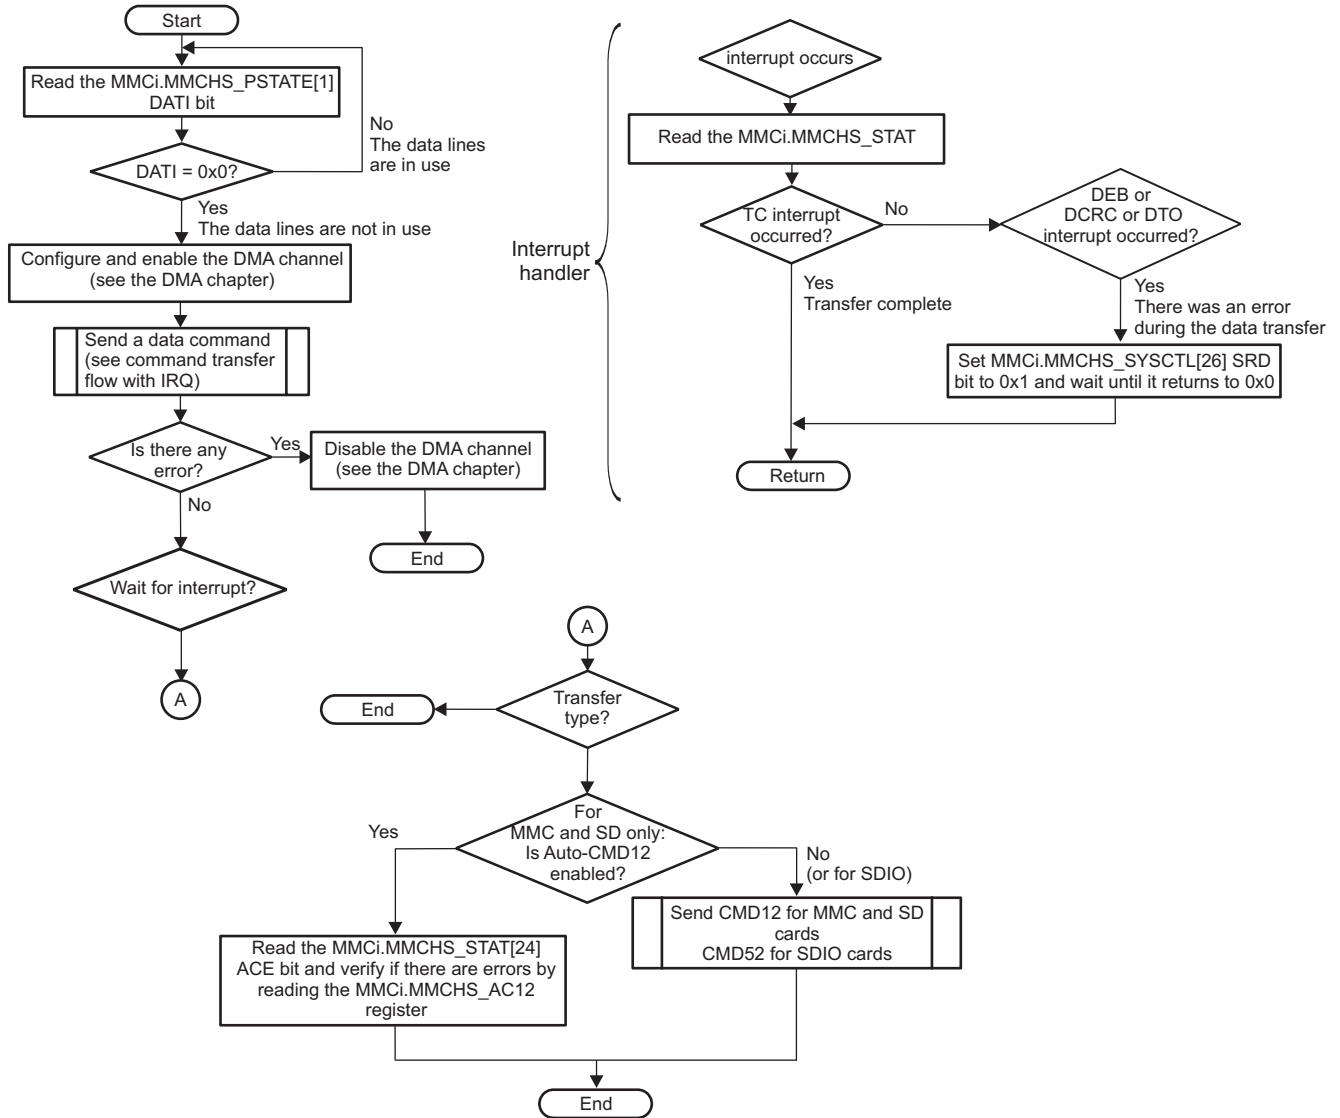

\*With OCR 0. In case of a CMD1 with OCR=0, a second CMD1 must be sent to the card with the "negotiated" voltage.

22.5.2.2 Read/Write Transfer Flow in DMA Mode with Interrupt

Figure 22-29 describes the read and write protocol in DMA mode with interrupt signaling. Refer to Chapter 9, DMA, for more information on the DMA settings.

Figure 22-29. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Interrupt

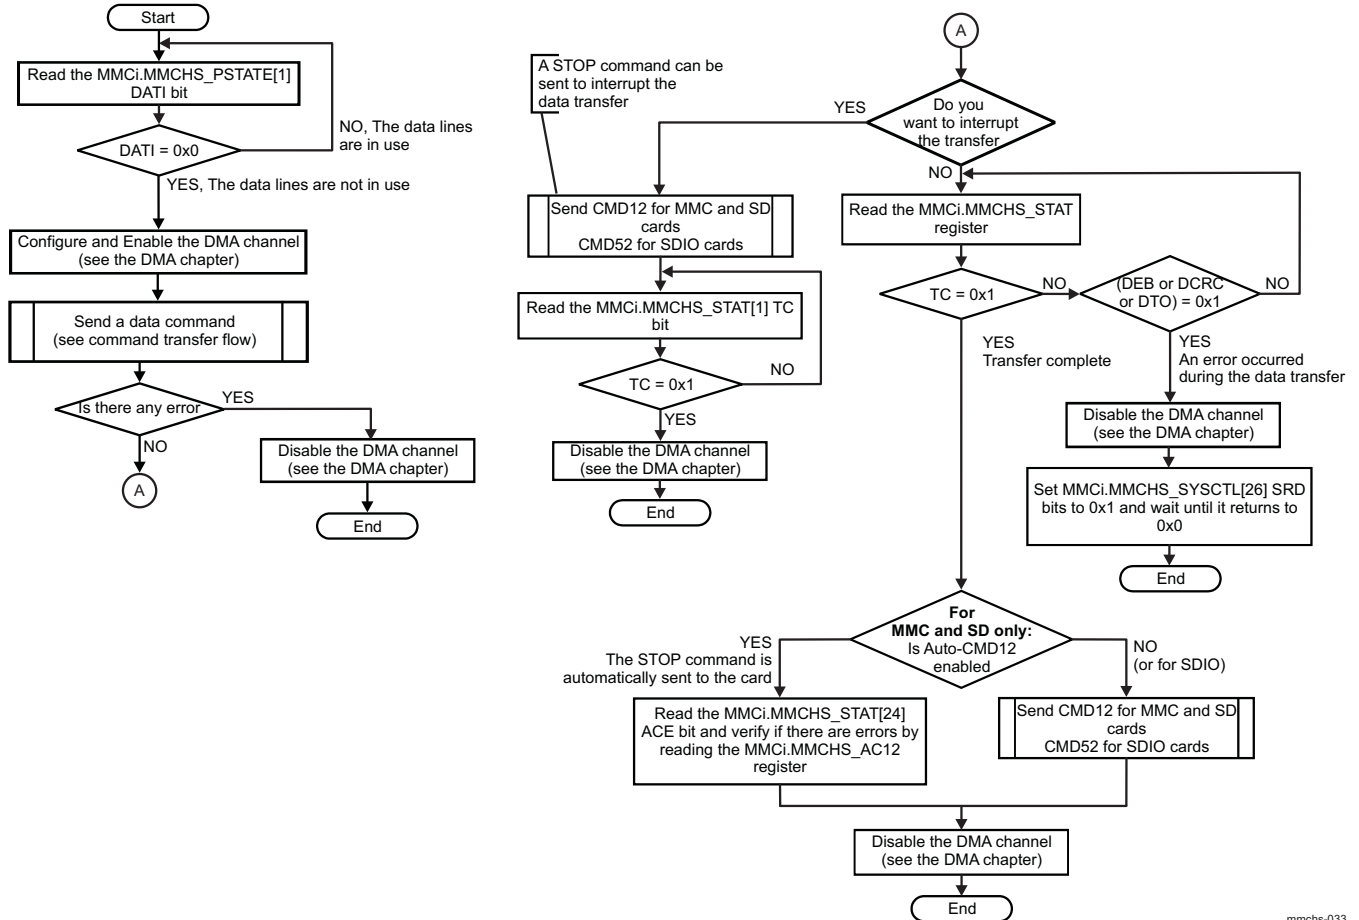

mmchs-032

### 22.5.2.3 Read/Write Transfer Flow in DMA Mode with Polling

Figure 22-30 describes the read and write protocol in DMA mode. Refer to Chapter 9, DMA, for more information on the DMA settings.

Figure 22-30. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Polling

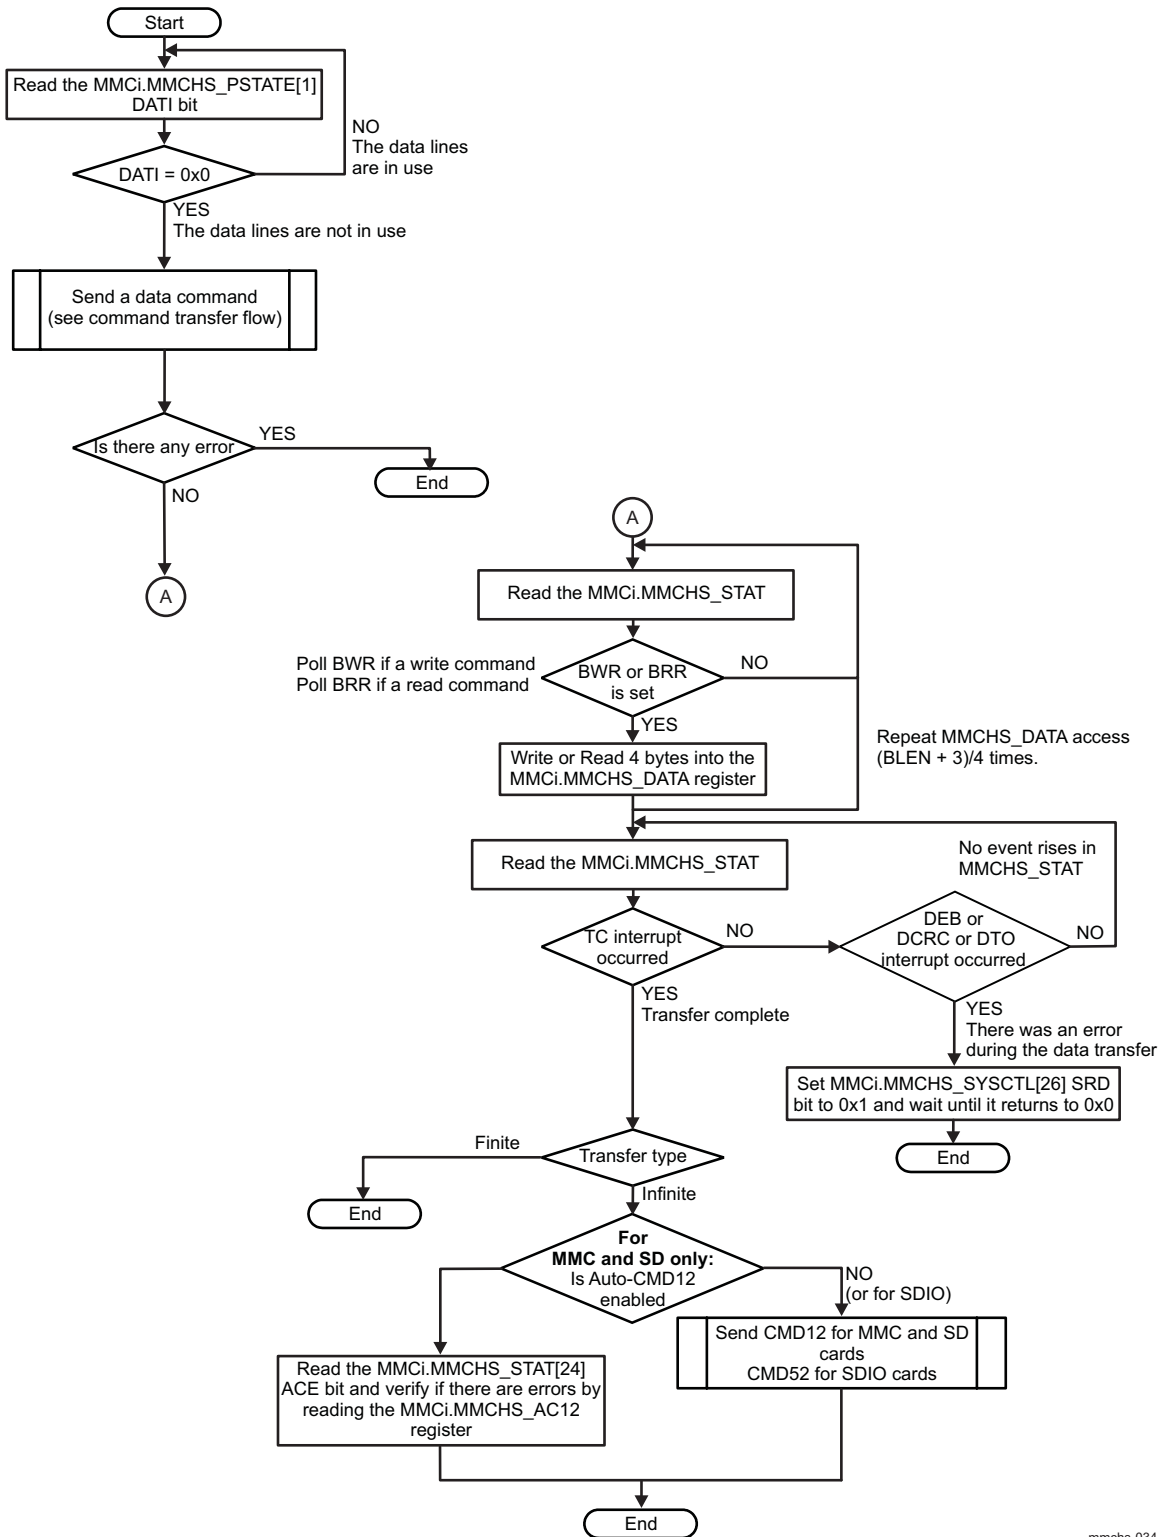

mmchs-033

22.5.2.4 Read/Write Transfer Flow without DMA with Polling

Figure 22-31 describes a read/write transfer without using the DMA and with polling.

Figure 22-31. MMC/SD/SDIO Controller Read/Write Transfer Flow without DMA with Polling

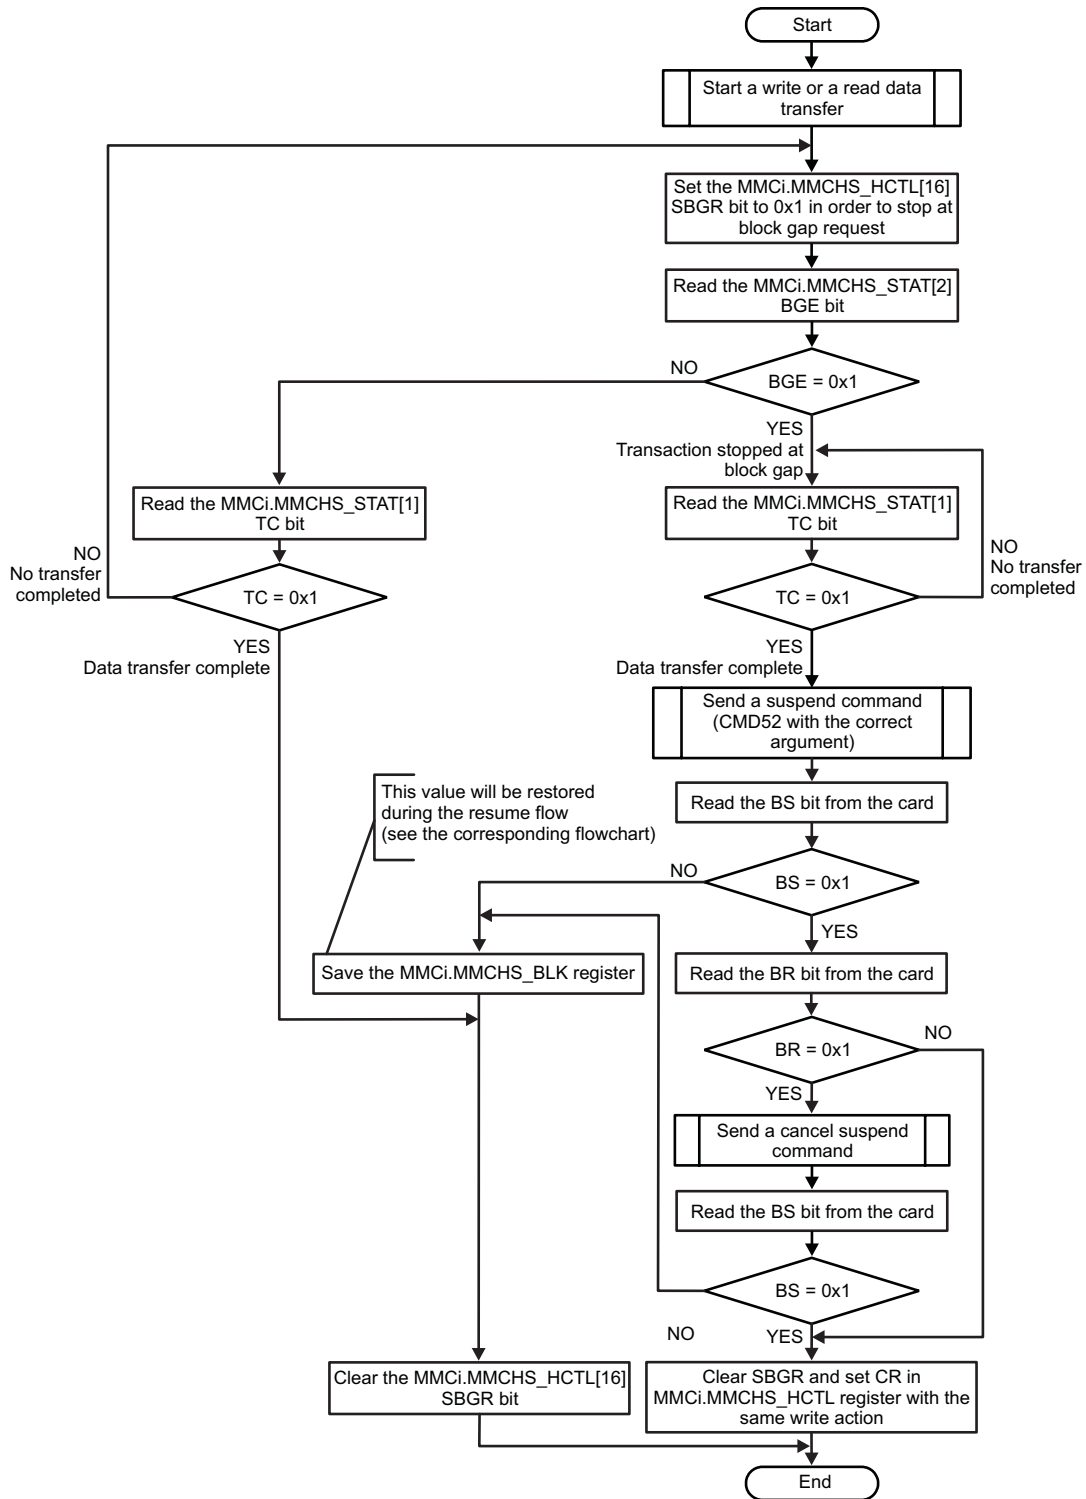

mmchs-034

22.5.2.6.1 Suspend Flow

Figure 22-33 describes the suspend flow for SDIO cards.

Figure 22-33. MMC/SD/SDIO Controller Suspend Flow

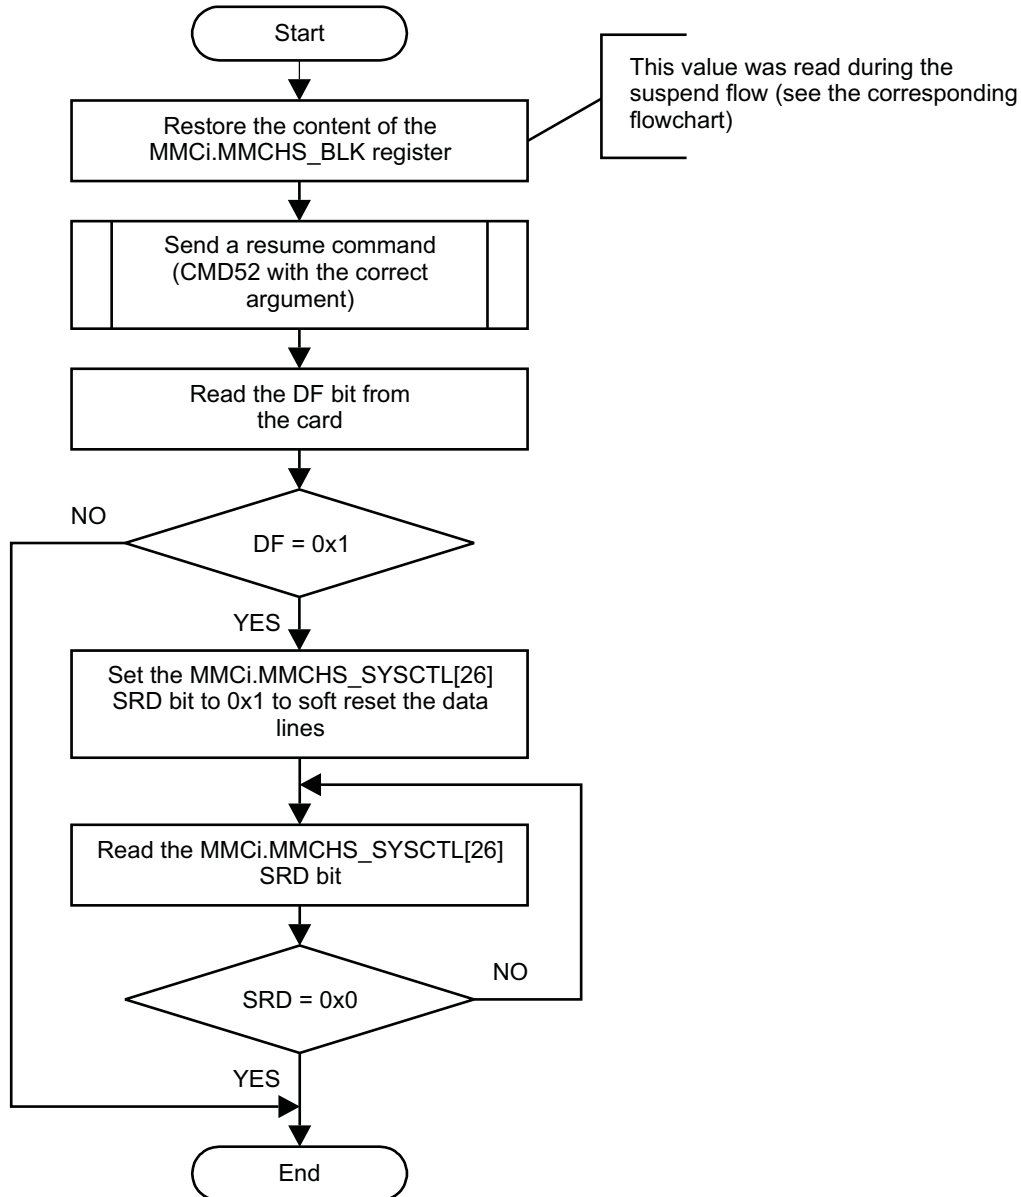

mmchs-038

### 22.5.2.6.2 Resume Flow

Figure 22-34 describes the resume flow for SDIO cards.

**Figure 22-34. MMC/SD/SDIO Controller Resume Flow**

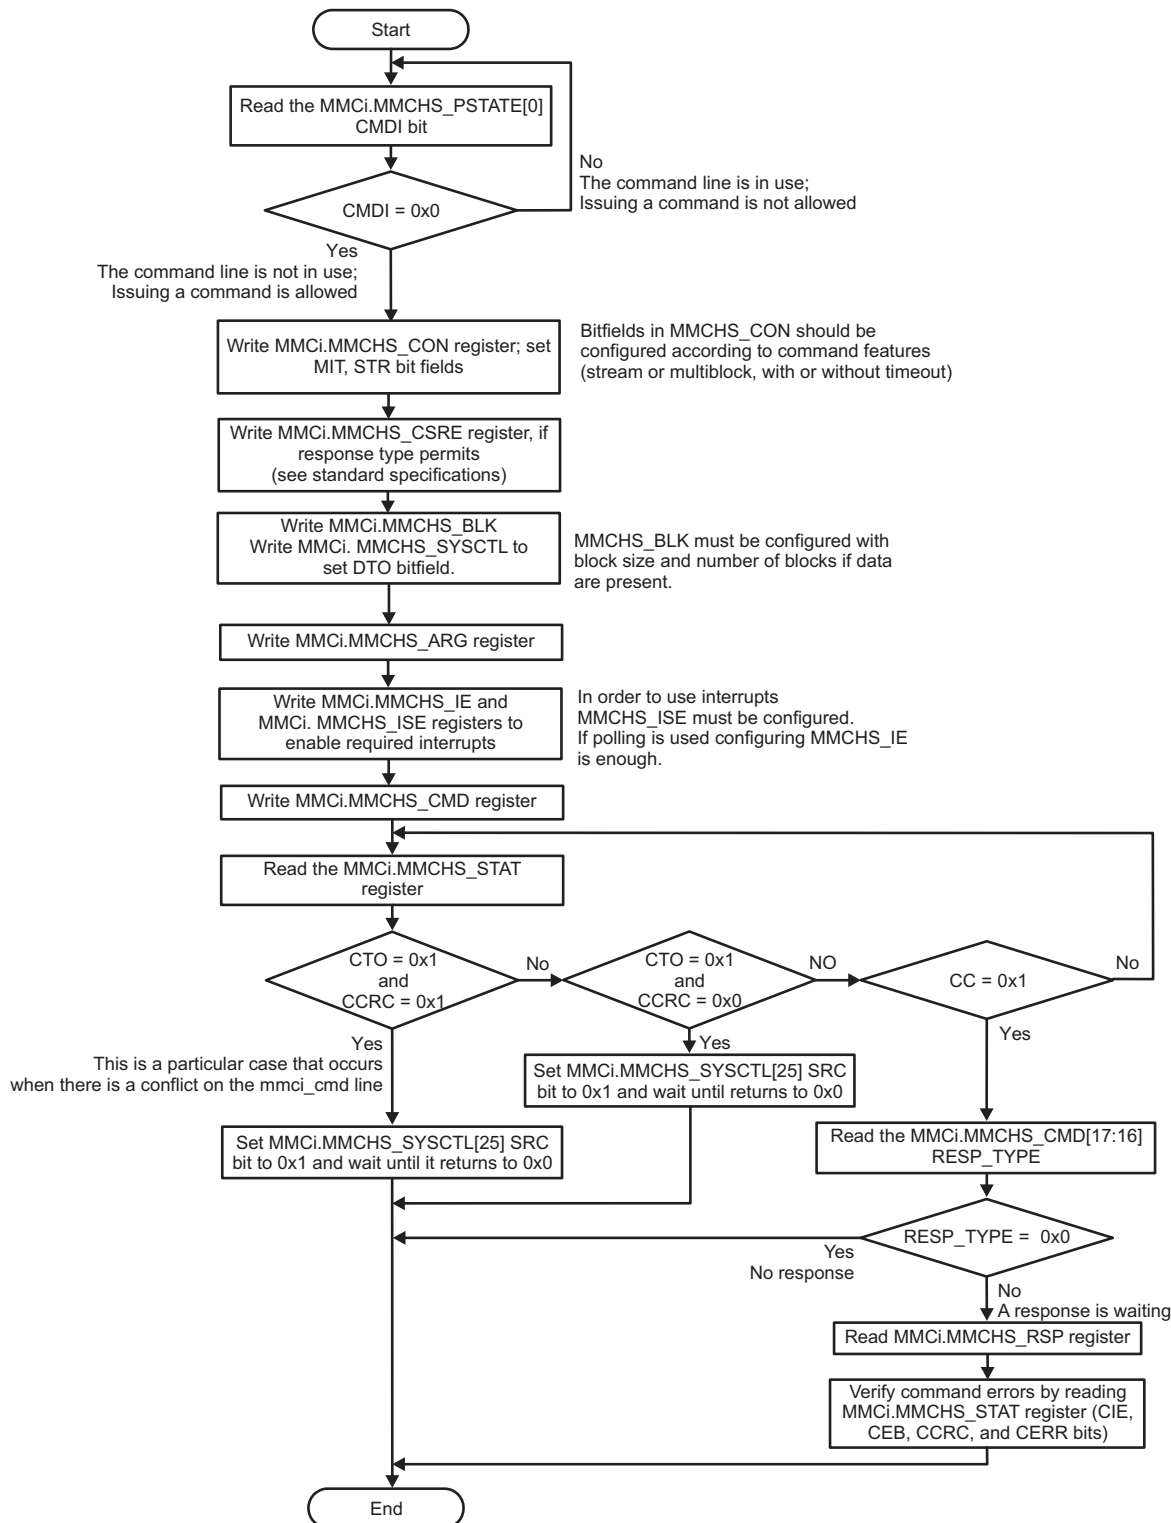

mmchs-039

### 22.5.2.7 Basic Operations - Steps Detailed

22.5.2.7.1 Command Transfer Flow

Figure 22-35 describes how to send a command to the card using polling instead of interrupts for event signaling.

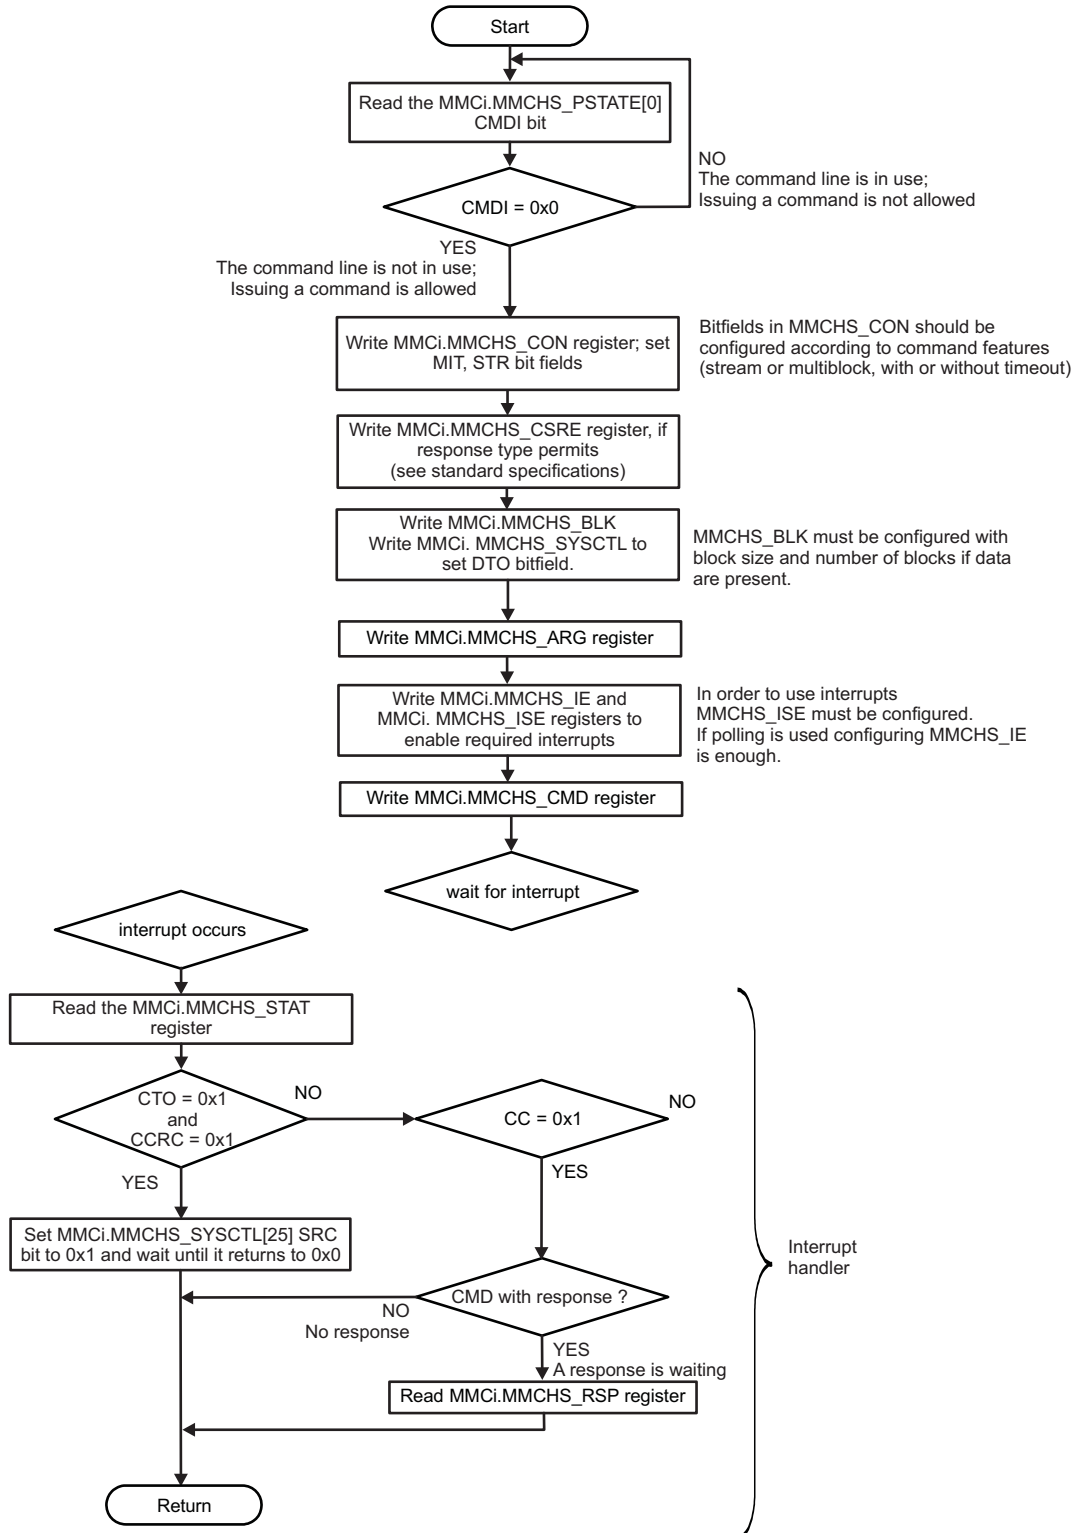

Figure 22-35. MMC/SD/SDIO Controller Command Transfer Flow with Polling

mmchs-040

Figure 22-36 describes how to send a command to the card using interrupts for event signaling.

Figure 22-36. MMC/SD/SDIO Controller Command Transfer Flow with Interrupts

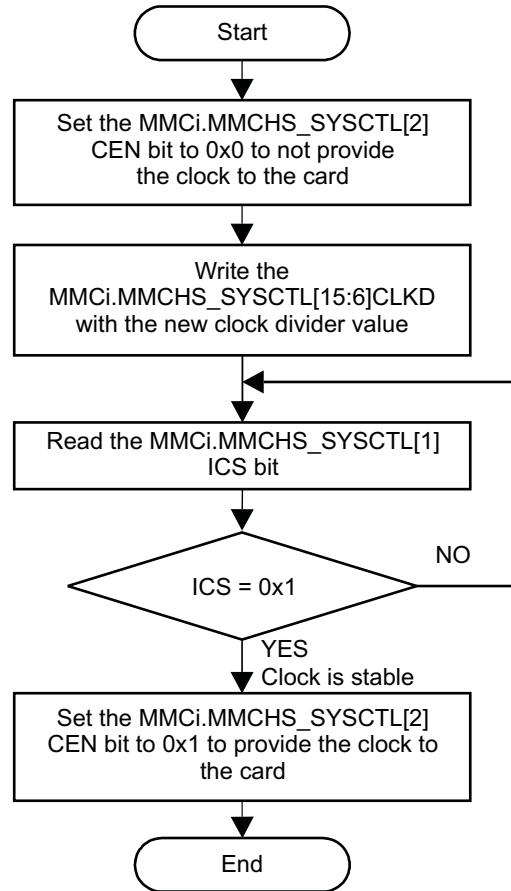

mmchs-041

### 22.5.2.7.2 MMCHS Clock Frequency Change

Figure 22-37 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 22-37. MMC/SD/SDIO Controller Clock Frequency Change Flow

mmchs-042

### 22.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS\_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL\_PBIAS\_LITE register settings.

See [Section 7.4.5, Extended-Drain I/O Pin and PBIAS Cell](#), for more information about the PBIAS\_LITE cell.

[Section 7.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#), describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

#### CAUTION

The BIAS voltage must be set using the procedure described in [Section 7.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#). Failure to follow this procedure can damage the MMCHS interface.

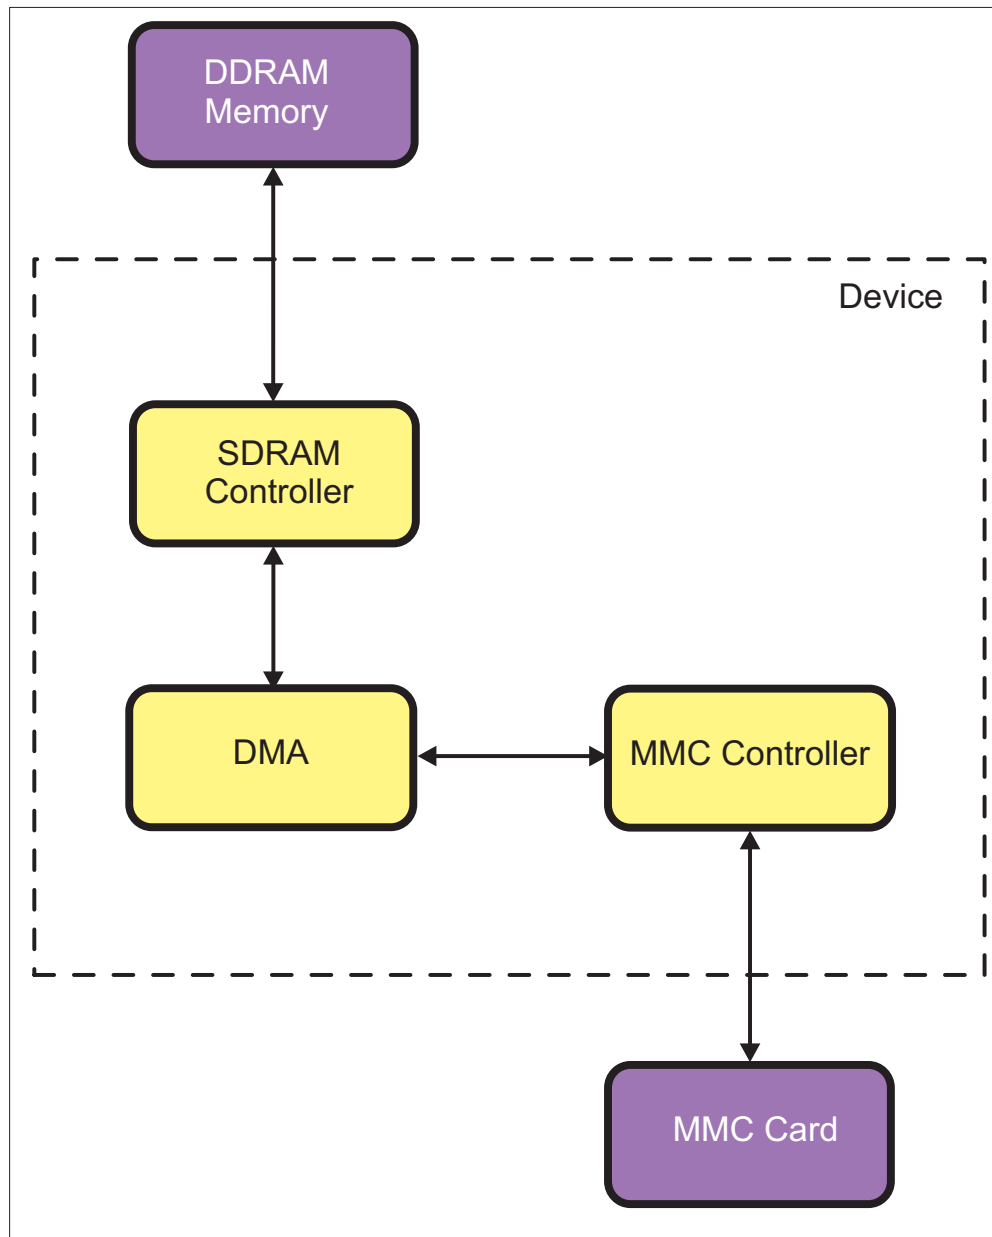

## 22.6 MMC/SD/SDIO Use Cases and Tips

### 22.6.1 MMCHS Controller Usage

#### 22.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. [Figure 22-38](#) gives an overview of MMCHS controller position in the use case.

**Figure 22-38. Overview**

mmchs\_050

For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 8 data lines.

- 1.8 V and 3.0 V voltage capabilities.

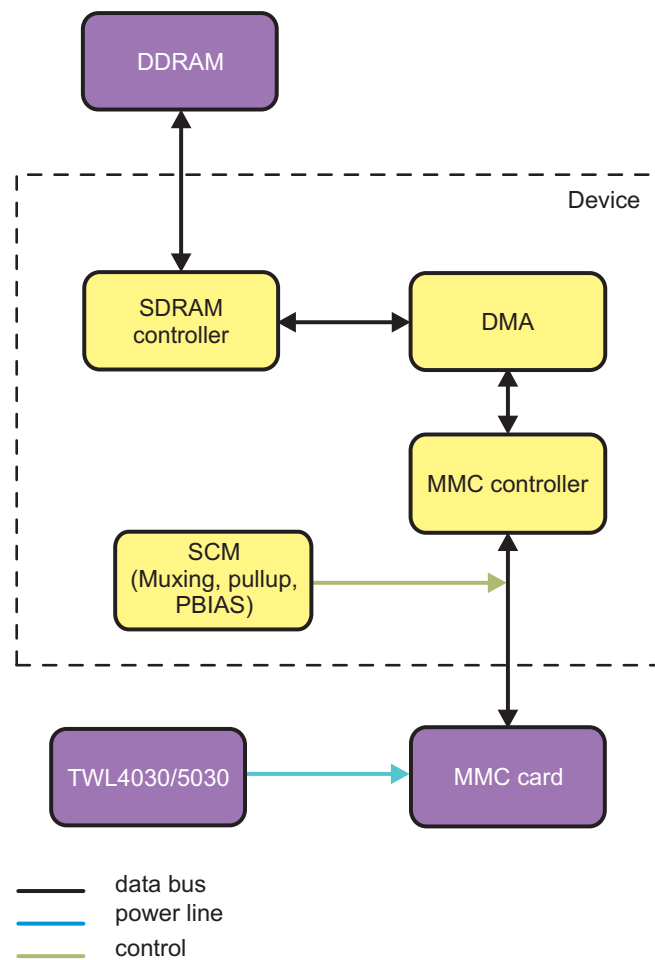

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. please refer to I2C TRM output to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

### 22.6.1.2 Environment

In order to operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. [Figure 22-39](#) gives the environment picture of the MMCHS controller.

**Figure 22-39. Environment**

mmchs\_051

#### 22.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

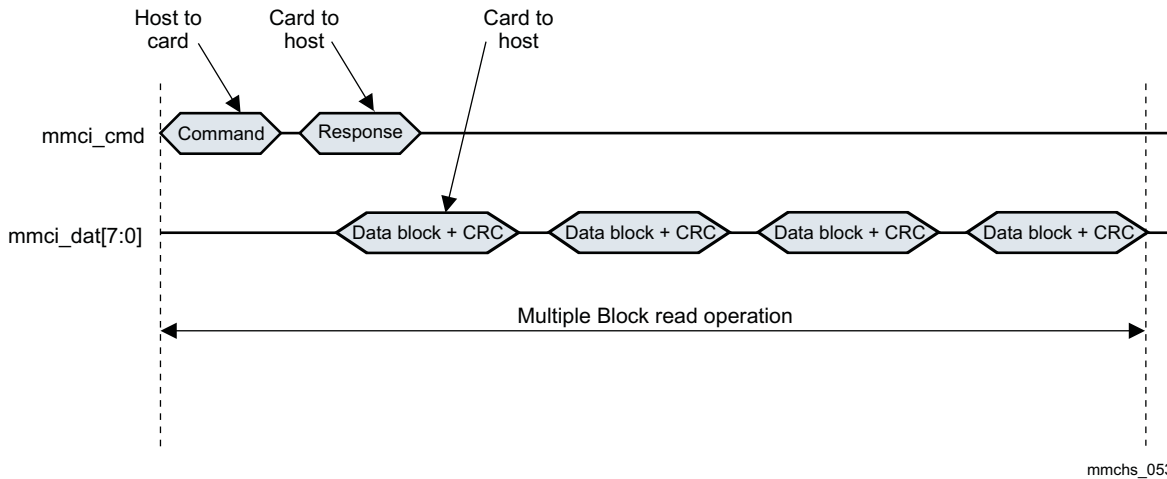

The data transfer type used by the MMCHS controller is a finite multiple block transfer. [Figure 22-40](#) illustrates a command transfer without data. [Figure 22-41](#) and [Figure 22-42](#) illustrate a multiple block transfer between the MMCHS controller and the MMC card.

**Figure 22-40. Command Transfer**

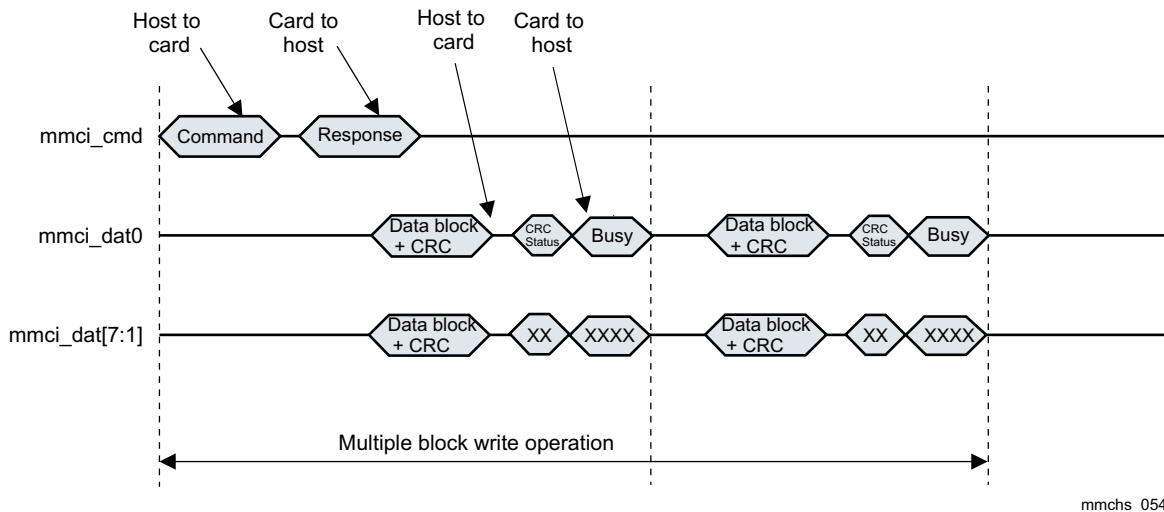

mmchs\_052

**Figure 22-41. Data Read Transfer**

mmchs\_053

**Figure 22-42. Data Write Transfer**

mmchs\_054

### 22.6.1.3 Programming Flow

### 22.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.
2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.
6. MMCHS controller pre-card identification configuration.

For more information about different steps the MMCHS controller goes through during initial configuration refer to [Section 22.5](#), *MMC/SD/SDIO Basic Programming Model*.

#### 22.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM\_ICLKEN1\_CORE[24] EN\_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM\_FCLKEN1\_CORE[24] EN\_MMCHS1).

[Table 22-8](#) shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

**Table 22-8. Register Print for the MMCHS1 controller's clocks Initialization**

Register Name	Register Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x01000000	MMCHS1 interface clock enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x01000000	MMCHS1 functional clock enabled

#### 22.6.1.3.1.2 MMCHS Controller Software Reset

In order to software reset the MMCHS1 controller, the following steps must be done:

1. Write 0x2 in MMCHS1.MMCHS\_SYSCONFIG register.
2. Wait until MMCHS1.MMCHS\_SYSSTATUS[0] RESETDONE turns 1.

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCONFIG	0x4809 C010	0x00000002	Activate software reset
MMCHS1.MMCHS_SYSSTATUS	0x4809 C014	0x00000001	Reset is over.

#### 22.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.MMCHS\_CAPA. Refer to [Table 22-9](#).

**Table 22-9. MMCHS Controller Voltage Capabilities Initialization**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CAPA	0x4809 C140	current_value   0x06000000	Activate VS18 and VS30 in <a href="#">MMCHS_CAPA</a> register.

#### 22.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values :

1. Default voltage support is set to 1.8 v in MMCHS1.MMCHS\_HCTL[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.MMCHS\_CON[0] OD.

3. MMC data bus width is set to 1 in MMCHS1.MMCHS\_HCTL[1] DTW.
4. MMC Card's power is off.
5. MMC Card's clock is on in MMCHS1.MMCHS\_SYSCTL[0] ICE and MMCHS1.MMCHS\_SYSCTL[2] CEN.
6. MMCHS controller bus power up in MMCHS1.MMCHS\_HCTL[8] SDBP.
7. MMC card's clock frequency is set to 150 KHz in MMCHS1.MMCHS\_SYSCTL[15:6] CLKD.

Table 22-10 shows the values that should be written in the right register pool.

**Table 22-10. MMC Controller Default Initialization Values**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x0000a007	card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

A small notice about MMCHS1.MMCHS\_HCTL. Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller is not in a card state mode which sets automatically MMCHS\_HCTL[8] SDBP bit to 0.

#### 22.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 KHz.

The INIt procedure is executed by setting MMCHS1.MMCHS\_CON[1] INIT bit field to 1 and by sending a dummy command, writing 0x00000000 in MMCHS1.MMCHS\_CMD register.

Table 22-11 shows the values that should be written in the right register pool.

**Table 22-11. MMCHS Controller INIT Procedure Start**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	current_value   0x00000002	sets MMCHS1.MMCHS_CON[1] INIT to 1
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	sends dummy command.

#### 22.6.1.3.1.6 MMCHS Controller Pre-card Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. MMC card's clock should now be 400 KHz according to MMC system spec requirements. Table 22-12 shows the values that should be written in the right register pool.

**Table 22-12. MMCHS Controller Pre-Card Identification Configuration**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

### 22.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS\_STAT register and command response if any is read from MMCHS1.MMCHS\_RSP10, MMCHS1.MMCHS\_RSP32, MMCHS1.MMCHS\_RSP54 and MMCHS1.MMCHS\_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, please refer to [Section 22.5 MMC/SD/SDIO Basic Programming Model](#).

#### 22.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see [Table 22-13](#)).

**Table 22-13. Sending CMD0**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00040001	Enables CC and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00040001	Enables CC and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends CMD0 whose opcode is 0.

#### 22.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see [Table 22-14](#)). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS\_RSP10 register.

**Table 22-14. Sending CMD5**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x05020000	Sends CMD5 whose opcode is 5 and response type is 48 bits.

#### 22.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see [Table 22-15](#)). This command will fail if there is no SD card version 2.X. In case of success the response will be in MMCHS1.MMCHS\_RSP10 register.

**Table 22-15. Sending CMD8**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.

**Table 22-15. Sending CMD8 (continued)**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x81a0000	Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled.

### 22.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see [Table 22-16](#)). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success, the response will be received in MMCHS1.MMCHS\_RSP10 register.

**Table 22-16. Sending CMD55**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x371a0000	Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled.

### 22.6.1.3.2.4 Sending CMD1

Once the card response is available in register MMCHS1.MMCHS\_RSP10, the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR.

This way, the card is notified of the Operating Voltage to work with.

**Table 22-17. Sending CMD1**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x01020000	Sends CMD1 whose opcode is 1 and response type is 48 bits.

Once the card response is available in register MMCHS1.MMCHS\_RSP10, the software should compare card OCR and host OCR, and then send a second CMD1 command with the cross-checked OCR. This tells the card what operating voltage to use.

### 22.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see [Table 22-18](#)). The response is 128 bit wide and is received in MMCHS1.MMCHS\_RSP10, MMCHS1.MMCHS\_RSP32, MMCHS1.MMCHS\_RSP54 and MMCHS1.MMCHS\_RSP76 registers.

**Table 22-18. Sending CMD2**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x02090000	Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled.

### 22.6.1.3.2.6 Sending CMD3

This command sets MMC card address (see [Table 22-19](#)). Useful when MMCHS controller switches to addressed mode.

**Table 22-19. Sending CMD3**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x031a0000	Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

### 22.6.1.3.3 MMC Bus Setting Change After Card Identification

After CMD3 command transfer is completed successfully, an auto-negotiation on voltage value an start. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull. [Table 22-20](#) gives several registers and their values.

**Table 22-20. MMC Bus Setting Change Table**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	Bus is now in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000B00	Bus power is on, 1.8V is selected.

**Table 22-20. MMC Bus Setting Change Table (continued)**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 240 which means that MMCHS controller is still supplying a 400 KHz clock.

#### 22.6.1.3.4 Reading the CSD Register of a MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, read and write transfer latency timings.

##### 22.6.1.3.4.1 Sending CMD9

This command asks the card to send its csd register's content (see [Table 22-21](#)). The 136 bit (128 bits are valid payload) response is received in MMCHS1.MMCHS\_RSP10, MMCHS1.MMCHS\_RSP32, MMCHS1.MMCHS\_RSP54 and MMCHS1.MMCHS\_RSP76 registers. CMD9 is an addressed command which means that card's address must be written in MMCHS1.MMCHS\_ARG register before the command is issued.

**Table 22-21. Sending CMD9**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x09090000	Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (please refer to MMC system specification from [www.mmca.org](http://www.mmca.org)).

Clock frequency change procedure is performed in several steps. Please refer to [Section 22.5](#), MMC/SD/SDIO Basic Programming Model, [Section 22.5.2.7.2](#), *MMCHS Clock Frequency Change*.

[Table 22-22](#) shows the value written in MMCHS1.MMCHS\_SYSCTL register.

**Table 22-22. MMCHS\_SYSCTL Value**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000147	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz.

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). In order to enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

Table 22-23 shows the set of register impacted by CMD7 issue action.

**Table 22-23. Sending CMD7**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x071a0000	Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext\_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used maximum data bus width 8. The second one enables high speed feature in the card.

#### 22.6.1.3.4.1.1 Setting Data Bus Width to 8

Table 22-24 shows the set of registers impacted by issuing CMD6.

**Table 22-24. Setting Data Bus Width with CMD6**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b70200	$(3 \ll 24)   (\text{byte\_address} \ll 16)   (\text{byte\_value} \ll 8)$ . byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width. This is done by changing MMCHS1.MMCHS\_CON configuration value.

**Table 22-25. MMCHS\_CON Value**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMCHS controller's data bus width is set to 8.

### 22.6.1.3.4.1.2 Enable High Speed Feature

Table 22-26 shows the set of registers impacted by issuing CMD6 issuing.

**Table 22-26. Enabling High Speed with CMD6**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b90100	$(3 \ll 24)   (\text{byte\_address} \ll 16)   (\text{byte\_value} \ll 8)$ . byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

**Table 22-27. MMCHS\_SYSCTL Value**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000087	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock.

### 22.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter, it is described in [Chapter 9, DMA](#).

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 22-23](#)).

A write transfer is a finite multiple block write transfer. In order to perform a write transfer, the following steps must be performed.

#### 22.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS\_ARG register. The registers impacted by this operation are as follows:

**Table 22-28. Setting Block Length**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x101a0000	Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000200	Block length is 512 = 0x200

### 22.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS\_ARG register. The registers impacted by this operation are as follows:

**Table 22-29. Setting Number of Blocks**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x171a0000	Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000008	Number of 512-byte blocks in 4 KB buffer is 8.

### 22.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to [Chapter 9, DMA](#).

**Table 22-30. CMD25 Issuing**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x193a0023	Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled.

**Table 22-30. CMD25 Issuing (continued)**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16)   (block_length)

### 22.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document, it is described in [Chapter 9, DMA](#).

Before any data transfer begins, the card must be selected by issuing CMD7 command ([Table 22-23](#)).

A read transfer is a finite multiple block write transfer. In order to perform a read transfer, the following steps must be performed.

#### 22.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS\_ARG register. See [Table 22-28](#).

#### 22.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS\_ARG register. See [Table 22-29](#).

#### 22.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to [Chapter 9, DMA](#).

**Table 22-31. CMD18 Issuing**

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x123a0033	Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16)   (block_length)

### 22.6.1.3.7 Dealing with High Capacity Cards

Unlike standard-capacity cards, memory addressing mode for high-capacity cards (SDHC and HC MMC) is in 512-byte block format instead of byte format. This means that byte and partial accesses are not allowed with high-capacity cards.

The 32-bit wide argument configured in the [MMCHS\\_ARG](#) register and sent in data transfer commands CMD17, CMD18, CMD24, and CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high-capacity cards, the block size is fixed at 512 bytes. Any data transfer, when the data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high-capacity card, which determines the capacity of the card  $\text{block\_count} \times 512$  bytes, is accessible through field `C_SIZE` in the card's CSD register version 2.0 for SD cards, or through the `SEC_COUNT` field in the card's `EXT_CSD` register for MMC cards compliant with MMC specification version 4.x.

To write/read a packet whose size is less than 512 bytes to/from a high-capacity card, write/read the whole 512-byte block that contains the range of bytes to modify/read.

## 22.7 MMC/SD/SDIO Register Manual

### 22.7.1 MMC/SD/SDIO Instance Summary

Table 22-32 lists the instance summary.

**Table 22-32. Instance Summary**

Module Name	Base Address	Size
MMCHS1	0x4809 C000	512 bytes
MMCHS2	0x480B 4000	512 bytes
MMCHS3	0x480A D000	512 bytes

### 22.7.2 MMC/SD/SDIO Registers Mapping Summary

Table 22-33 lists the MMC/SD/SDIO1 to MMC/SD/SDIO3 registers. Table 22-34 through Table 22-80 describe the register bits.

**CAUTION**

The MMC/SD/SDIOi registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

**Table 22-33. MMC/SD/SDIO1 Register Summary**

Register	Type	Register Width (Bits)	Offset Address	MMCHS1 Physical Address	MMCHS2 Physical Address	MMCHS3 Physical Address
MMCHS_SYSCONFIG	RW	32	0x10	0x4809 C010	0x480B 4010	0x480A D010

	0x480B 4010		MMCHS2
<b>Description</b>	System Configuration Register This register allows controlling various parameters of the Interconnect interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CLOCKACTIVITY		Reserved			SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE							

Bits	Field Name	Description	Type	Reset
31:10	Reserved	These bits are initialized to zero, and writes to them are ignored. Reads return 0	R	0x00000
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock  0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x2: Functional clock is maintained. Interface clock may be switched-off. 0x3: Interface and Functional clocks are maintained.	RW	0x0
7:5	Reserved	These bits are initialized to zero, and writes to them are ignored. Reads return 0	R	0
4:3	SIDLEMODE	Power management  0x0: If an idle request is detected, the MMC/SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted. 0x1: If an idle request is detected, the request is ignored and the module keeps on behaving normally. 0x2: If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit MMChS.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 1). 0x3: Reserved - do not use	RW	0x2
2	ENAWAKEUP	Wake-up feature control  0x0: Wake-up capability is disabled 0x1: Wake-up capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0.  Read 0x0: Normal mode Write 0x0: No effect. Read 0x1: The module is reset.	RW	0

Bits	Field Name	Description	Type	Reset
		Write 0x1: Trigger a module reset.		
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the interconnect and MMC interface activity	RW	1

<b>Description</b>	Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCi.MMCHS_CSRE[I] is set to 1, if the corresponding bit at the same position in the response MMCi.MMCHS_RSP10[I] is set to 1, the host controller indicates a card error (MMCi.MMCHS_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (MMCi.MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCi.MMCHS_RSP76) for possible card errors.

<b>Description</b>	System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCi.MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCi.MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCi.MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCi.MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCi.MMCHS_STAT[5] BRR bit) and DMA requests if enabled.

	0x480B 402C		MMCHS2
<b>Description</b>	Configuration register This register is used: - to select the functional mode for any card. - to send an initialization sequence to any card. - to enable the detection on the mmci_dat[1] signal of a card interrupt for SDIO cards only. And also to configure: - specific data and command transfers for MMC cards only. - the parameters related to the card detect and write protect input signals.

			HR
			INIT
			OD

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Reserved bit field. Do not write any value	R	0x00000
16	CLKEXTFREE	<p>External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCI.MMCHS_SYSCCTL[2] CEN bit is set.</p> <p>0x0: External card clock is cut off outside active transaction period.</p> <p>0x1: External card clock is maintain even out of active transaction period only if MMCI.MMCHS_SYSCCTL[2] CEN bit is set.</p>	RW	0
15	PADEN	<p>Control Power for MMC Lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCI.MMCHS_CON[11] CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.</p> <p>0x1: ADPIDLE module pin is forced to active state.</p>	RW	0
14	OBIE	<p>Out-of-Band Interrupt Enable (MMC cards only). This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled.</p> <p>0x1: Out-of-Band interrupt detection enabled.</p>	RW	0
13	OBIP	<p>Out-of-Band Interrupt Polarity (MMC cards only). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level.</p> <p>0x1: active low level.</p>	RW	0
12	CEATA	<p>CE-ATA control mode (MMC cards compliant with CE-ATA): By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.</p>	RW	0
11	CTPL	<p>Control Power for mmci_dat[1] line (MMC and SD cards): By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.</p> <p>SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.</p>	RW	0
10:9	DVAL	<p>Debounce filter value (All cards) This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period.</p> <p>0x1: 231 us debounce period.</p>	RW	0x3

Bits	Field Name	Description	Type	Reset
		0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period.		
8	WPP	Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
7	CDP	Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
6	MIT	MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCI.MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards)	RW	0
4	MODE	Mode select (All cards) These bits select the functional mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCI.MMCHS_CMD register. 0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer. 0x1: Stream oriented data transfer.	RW	0

Bits	Field Name	Description	Type	Reset
2	HR	<p>Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register <a href="#">MMCHS_CON[OD]</a> must be set to 1. When <a href="#">MMCi.MMCHS_CON[12]</a> CEATA bit is set to 1 and <a href="#">MMCi.MMCHS_ARG</a> set to 0x00000000, when writing 0x00000000 into <a href="#">MMCi.MMCHS_CMD</a> register, the host controller performs a 'command completion signal disable' token (i.e. <code>mmci_cmd</code> line held to '0' during 47 cycles followed by a 1).</p> <p>0x0: The host does not generate a 48-bit response instead of a command.</p> <p>0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0
1	INIT	<p>Send initialization stream (All cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the <code>mmci_cmd</code> line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (<a href="#">MMCi.MMCHS_SYSCTL[15:6]</a> CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. <a href="#">MMCi.MMCHS_STAT[0]</a> CC bit can be polled.</p> <p>0x0: The host does not send an initialization sequence.</p> <p>0x1: The host sends an initialization sequence.</p>	RW	0
0	OD	<p>Card open drain mode (Only for MMC cards). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register <a href="#">MMCi.MMCHS_CON[2]</a> HR bit)</p> <p>0x0: No Open Drain</p> <p>0x1: Open Drain or Broadcast host response</p>	RW	0

NBLK								Reserved				BLEN																																																			
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>														<b>Type</b>	<b>Reset</b>																																														
31:16	NBLK	Blocks count for current transfer. This register is enabled when Block count Enable (MMCi.MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.														RW	0x0000																																														

Bits	Field Name	Description	Type	Reset
		0x0: Stop count		
		0x1: 1 block		
		0x2: 2 blocks		
		0xFFFF: 65535 blocks		
15:11	Reserved	Reserved bit field. Do not write any value	R	0x00
10:0	BLEN	Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.  0x0: No data transfer 0x1: 1 byte block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x1FF: 511 bytes block length 0x200: 512 bytes block length 0x3FF: 1023 bytes block length 0x400: 1024 bytes block length	RW	0x000

Reserved		INDX						CMD_TYPE	DP	CICE	CCCE	Reserved	RSP_TYPE	Reserved										MSBS	DDIR	Reserved	ACEN	BCE	DE																																				
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>		<b>Type</b>	<b>Reset</b>																																																												
31:30	Reserved	Reserved bit field. Do not write any value		R	0x0																																																												
29:24	INDX	Command index Binary encoded value from 0 to 63 specifying the command number send to card  0x0: CMD0 or ACMD0 0x1: CMD1 or ACMD1 0x3F: CMD63 or ACMD63		RW	0x00																																																												
23:22	CMD_TYPE	Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands.  0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command		RW	0x0																																																												
21	DP	Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line -Command with no data transfer but using busy signal on mmci_dat[0] -Resume command  0x0: Command with no data transfer 0x1: Command with data transfer		RW	0																																																												

Bits	Field Name	Description	Type	Reset
20	CICE	<p>Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCi.MMCHS_STAT[19] CIE bit set to 1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued.</p> <p>0x0: Index check disable 0x1: Index check enable</p>	RW	0
19	CCCE	<p>Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCi.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.</p> <p>0x0: CRC7 check disable 0x1: CRC7 check enable</p>	RW	0
18	Reserved	Reserved bit field. Do not write any value.	R	0
17:16	RSP_TYPE	<p>Response type. This bits defines the response type of the command.</p> <p>0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response</p>	RW	0x0
15:6	Reserved	Reserved bit field. Do not write any value.	R	0x000
5	MSBS	<p>Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0.</p> <p>0x0: Single block. If this bit is 0, it is not necessary to set the register MMcI.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCi.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCi.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.</p>	RW	0
4	DDIR	<p>Data transfer Direction. Select This bit defines either data transfer will be a read or a write.</p> <p>0x0: Data Write (host to card) 0x1: Data Read (card to host)</p>	RW	0
3	Reserved	Reserved bit field. Do not write any value.	R	0
2	ACEN	<p>Auto CMD12 Enable. (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. For CE-ATA commands (MMCi.MMCHS_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated.</p> <p>0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.</p>	RW	0
1	BCE	<p>Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer.</p> <p>0x0: Block count disabled for infinite transfer.</p>	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Block count enabled for multiple block transfer with known number of blocks		
0	DE	DMA Enable. This bit is used to enable DMA mode for host data access.	RW	0
		0x0: DMA mode disable		
		0x1: DMA mode enable

<b>Address Offset</b>	0x120																																																																	
<b>Physical Address</b>	0x4809 C120	<b>Instance</b> MMCHS1																																																																
	0x480A D120	MMCHS3																																																																
	0x480B 4120	MMCHS2																																																																
<b>Description</b>	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

DATA																																																																		

Bits	Field Name	Description	Type	Reset
15:12	Reserved	Reserved bit field. Do not write any value	R	0x0
11	BRE	<p>Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCi.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCi.MMCHS_STAT[5] BRR bit).</p> <p>Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.</p>	R	0
10	BWE	<p>Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data.</p> <p>Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.</p>	R	0
9	RTA	<p>Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Read data transfer on going.</p>	R	0
8	WTA	<p>Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Write data transfer on going.</p>	R	0
7:3	Reserved	Reserved bit field. Do not write any value	R	0x00
2	DLA	<p>mmci_dat line active. This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: mmci_dat Line inactive Read 0x1: mmci_dat Line active</p>	R	0
1	DATI	<p>Command inhibit (mmci_dat). This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit).</p> <p>Read 0x0: Issuing of command using the mmci_dat lines is allowed Read 0x1: Issuing of command using mmci_dat lines is not allowed</p>	R	0

Bits	Field Name	Description	Type	Reset
0	CMDI	<p>Command inhibit(mmc_i_cmd).</p> <p>This status bit indicates that the mmc_i_cmd line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> <li>- After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit).</li> <li>- After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared.</li> </ul> <p>Read 0x0: Issuing of command using mmc_i_cmd line is allowed</p> <p>Read 0x1: Issuing of command using mmc_i_cmd line is not allowed</p>	R	0

Bits	Field Name	Description	Type	Reset																																																																								
31:28	Reserved	Reserved bit field. Do not write any value.	R	0x00																																																																								
27	OBWE	<p>Wake-up event enable for 'Out-of-Band' Interrupt. This bit enables wake-up events for 'Out-of-Band' assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCi.MMCHS_CON[14] OBIE bit is not set.</p> <p>0x0: Disable wakeup on 'Out-of-Band' Interrupt.</p> <p>0x1: Enable wakeup on 'Out-of-Band' Interrupt.</p>	RW	0																																																																								
26	REM	<p>Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit).</p> <p>0x0: Disable wakeup on card removal.</p> <p>0x1: Enable wakeup on card removal.</p>	RW	0																																																																								

Bits	Field Name	Description	Type	Reset
25	INS	Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card insertion. 0x1: Enable wakeup on card insertion.	RW	0
24	IWE	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCi.MMCHS_IE[8] CIRQ_ENABLE bit). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	Reserved	Reserved bit field. Do not write any value	R	0x0
19	IBG	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmci_dat line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0
17	CR	Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0
16	SBGR	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	Reserved	Reserved bit field. Do not write any value.	R	0x0
11:9	SDVS	SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMcI.MMCHS_CAPA[25] VS30 bit, MMcI.MMCHS_CAPA[24] VS33 bit) before starting a transfer. 0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical)	RW	0x0

Bits	Field Name	Description	Type	Reset
		MMCHS2: This field must be set to 0x5. MMCHS3: This field must be set to 0x5.		
8	SDBP	SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7:2	Reserved	Reserved bit field. Do not write any value.	R	0x00
1	DTW	Data transfer width. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with <i>MMC standard specification 4.x</i> This register has no effect when the MMC 8-bit mode is selected (MMCi.MMCHS_CON[5] DW8 bit set to 1) For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (mmci_dat[0] used) 0x1: 4-bit Data width (mmci_dat[3:0] used)	RW	0
0	Reserved	Reserved bit field. Do not write any value.	R	0

<b>Description</b>	SD system control register. This register defines the system controls to set software resets, clock frequency management and data timeout. <a href="#">MMCHS_SYSCTL[31:24]</a> = Software resets <a href="#">MMCHS_SYSCTL[23:16]</a> = Timeout control <a href="#">MMCHS_SYSCTL[15:0]</a> = Clock control																															
<b>Type</b>	RW																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Reserved				SRD	SRC	SRA	Reserved				DTO				CLKD				Reserved				CEN	ICS	ICE						

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved bit field. Do not write any value.	R	0x00
26	SRD	Software reset for mmci_dat line. This bit is set to 1 for reset and released to 0 when completed .mmci_dat finite state machine in both clock domain are also reset. Here below are the registers cleared by the <a href="#">MMCHS_SYSCTL[26]</a> SRD bit: MMCi.MMCHS_DATA MMCi.MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI MMCi.MMCHS_HCTL: SBGR and CR MMCi.MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized.  0x0: Reset completed 0x1: Software reset for mmci_dat line	RW	0
25	SRC	Software reset for mmci_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmci_cmd finite state machine in both clock domain are also reset. Here below are the registers cleared by the MMcI.MMCHS_SYSCTL[25] SRC bit: MMCi.MMCHS_PSTATE: CMDI MMCi.MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized.  0x0: Reset completed 0x1: Software reset for mmci_cmd line	RW	0
24	SRA	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.  0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	Reserved	Reserved bit field. Do not write any value.	R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which mmci_dat lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCi.MMCHS_CAPA[5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCi.MMCHS_STAT[20] DTO bit). The MMcI.MMCHS_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write.  0x0: TCF x 2 <sup>13</sup> 0x1: TCF x 2 <sup>14</sup> 0xE: TCF x 2 <sup>27</sup> 0xF: Reserved	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmci_clk pin of either the memory card (MMC, SD or SDIO).  0x0: Clock Ref bypass 0x1: Clock Ref bypass 0x2: Clock Ref / 2 0x3: Clock Ref / 3 0x3FF: Clock Ref / 1023	RW	0x000
5:3	Reserved	Reserved bit field. Do not write any value	R	0x0
2	CEN	Clock enable. This bit controls if the clock is provided to the card or not.  0x0: The clock is not provided to the card . Clock frequency can be changed .	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: The clock is provided to the card and can be automatically gated when MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCI.MMCHS_SYSCTL[1] ICS bit).		
1	ICS	Internal clock stable (status)This bit indicates either the internal clock is stable or not.  Read 0x0: The internal clock is not stable.  Read 0x1: The internal clock is stable after enabling the clock (MMCI.MMCHS_SYSCTL[0] ICE bit) or after changing the clock ratio (MMCI.MMCHS_SYSCTL[15:6] CLKD bits).	R	0
0	ICE	Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.  0x0: The internal clock is stopped (very low power state).  0x1: The internal clock oscillates and can be automatically gated when MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) .	RW	0

**Table 22-68. MMCHS\_STAT**

<b>Address Offset</b>	0x130																																							
<b>Physical Address</b>	0x4809 C130								<b>Instance</b>								MMCHS1								0x480A D130								MMCHS3							
	0x480B 4130																MMCHS2																							
<b>Description</b>	Interrupt status register The interrupt status regroups all the status of the module internal events that can generate an interrupt. <a href="#">MMCHS_STAT[31:16]</a> = Error Interrupt Status <a href="#">MMCHS_STAT[15:0]</a> = Normal Interrupt Status																																							
<b>Type</b>	RW																																							
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
	Reserved	BADA	CERR	Reserved	ACE	Reserved	DEB	DCRC	DTO	CIE	CEB	CCRC	CTO	ERRI	Reserved								OBI	CIRQ	Reserved	BRR	BWR	Reserved	BGE	TC	CC									

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29	BADA	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: - During a read access to the data register (MMCi.MMCHS_DATA) while buffer reads are not allowed (MMCi.MMCHS_PSTATE[11] BRE bit =0) - During a write access to the data register (MMCi.MMCHS_DATA) while buffer writes are not allowed (MMCi.MMCHS_PSTATE[10] BWE bit=0)  Read 0x0: No Interrupt. Write 0x0: Status bit unchanged Read 0x1: Bad Access Write 0x1: Status is cleared	RW	0
28	CERR	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCi.MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCi.MMCHS_RSP76 register to detect error bits in the command response.  Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Card error Write 0x1: Status is cleared	RW	0
27:25	Reserved	Reserved bit field. Do not write any value	R	0x0
24	ACE	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.  Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: AutoCMD12 error Write 0x1: Status is cleared	RW	0
23	Reserved	Reserved bit field. Do not write any value	R	0
22	DEB	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmci_dat line or at the end position of the CRC status in write mode.  Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Data end bit error Write 0x1: Status is cleared	RW	0
21	DCRC	Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.  Read 0x0: No Error. Write 0x0: Status bit unchanged Read 0x1: Data CRC error Write 0x1: Status is cleared	RW	0
20	DTO	Data timeout error. This bit is set automatically according to the following conditions: - Busy timeout for R1b, R5b response type. - Busy timeout after write CRC status. - Write CRC status timeout. - Read data timeout.  Read 0x0: No error Write 0x0: Status bit unchanged	RW	0

Bits	Field Name	Description	Type	Reset
		Read 0x1: Time out Write 0x1: Status is cleared		
19	CIE	Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCi.MMCHS_CMD[20] CICE). Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command index error Write 0x1: Status is cleared	RW	0
18	CEB	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command end bit error Write 0x1: Status is cleared	RW	0
17	CCRC	Command CRC Error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCi.MMCHS_CMD[19] CCCE). Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Command CRC error Write 0x1: Status is cleared	RW	0
16	CTO	Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Time Out Write 0x1: Status is cleared	RW	0
15	ERRI	Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCi.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI	Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCi.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCi.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared.	R	0

Bits	Field Name	Description	Type	Reset
8	CIRQ	<p>Card interrupt.</p> <p>This bit is only used for SD and SDIO cards.</p> <p>In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup).</p> <p>In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end.</p> <p>All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting MMCi.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCi.MMCHS_IE[8] CIRQ_ENABLE is set to 1.</p> <p>Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt</p> <p>Read 0x1: Generate card interrupt</p>	R	0
7:6	Reserved	Reserved bit field. Do not write any value.	RW	00
5	BRR	<p>Buffer read ready.</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCi.MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready.</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCi.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	Reserved	Reserved bit field. Do not write any value	R	0
2	BGE	<p>Block gap event.</p> <p>When a stop at block gap is requested (MMCi.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCi.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Transaction stopped at block gap</p> <p>Write 0x1: Status is cleared</p>	RW	0

Bits	Field Name	Description	Type	Reset
1	TC	<p>Transfer completed.</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCi.MMCHS_HCTL[16] SBGR bit).</p> <p>This bit is also set when exiting a command in a busy state (if the command has a busy notification capability).</p> <p>In Read mode: This bit is automatically set on completion of a read transfer (MMCi.MMCHS_PSTATE[9] RTA bit).</p> <p>In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCi.MMCHS_PSTATE[2] DLA bit).</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data transfer complete</p> <p>Write 0x1: Status is cleared</p>	RW	0
0	CC	<p>Command complete.</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCi.MMCHS_PSTATE[0] CMDI bit)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCi.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCi.MMCHS_STAT[0] CC bit).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>Read 0x0: No Command complete</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Command complete</p> <p>Write 0x1: Status is cleared</p>	RW	0

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value.	R	0
29	BADA_ENABLE	Bad access to data space Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
28	CERR_ENABLE	Card error interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
27:25	Reserved	Reserved bit field. Do not write any value	R	0x0
24	ACE_ENABLE	Auto CMD12 error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
23	Reserved	Reserved bit field. Do not write any value	R	0
22	DEB_ENABLE	Data end bit error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
21	DCRC_ENABLE	Data CRC error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
20	DTO_ENABLE	Data timeout error Interrupt Enable 0x0: The data timeout detection is deactivated. The host controller provides the clock to the card until the card sends the data or the transfer is aborted. 0x1: The data timeout detection is enabled.	RW	0
19	CIE_ENABLE	Command index error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
18	CEB_ENABLE	Command end bit error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
17	CCRC_ENABLE	Command CRC error Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
16	CTO_ENABLE	Command timeout error Interrupt Enable	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Masked 0x1: Enabled		
15	NULL	Fixed to 0 The host driver shall control error interrupts using the Error Interrupt Signal Enable register. Writes to this bit are ignored.	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI_ENABLE	Out-of-Band interrupt Enable A write to this register when MMCi.MMCHS_CON[14] OBIE is set to '0' is ignored. 0x0: Masked 0x1: Enabled	RW	0
8	CIRQ_ENABLE	Card interrupt Enable A clear of this bit also clears the corresponding status bit. During 1-bit mode, if the interrupt routine does not remove the source of a card interrupt in the SDIO card, the status bit is reasserted when this bit is set to 1. This bit must be set to 1 when entering in smart idle mode to enable system to identify wakeup event and to allow controller to clear internal wakeup source. 0x0: Masked 0x1: Enabled	RW	0
7:6	Reserved	Reserved bit field. Do not write any value	RW	00
5	BRR_ENABLE	Buffer Read Ready Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
4	BWR_ENABLE	Buffer Write Ready Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
3	Reserved	Reserved bit field. Do not write any value.	R	0
2	BGE_ENABLE	Block Gap Event Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
1	TC_ENABLE	Transfer completed Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0
0	CC_ENABLE	Command completed Interrupt Enable 0x0: Masked 0x1: Enabled	RW	0

**Table 22-74. MMCHS\_AC12**

<b>Address Offset</b>	0x13C	
<b>Physical Address</b>	0x4809 C13C	<b>Instance</b> MMCHS1
	0x480A D13C	MMCHS3
	0x480B 413C	MMCHS2
<b>Description</b>	Auto CMD12 Error Status Register. The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMChS.AC12 register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled (MMChS.CMD[2] ACEN bit) and Auto CMD12Error (MMChS.STAT[24] ACE bit) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data.	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																							CNI	Reserved	ACIE	ACEB	ACCE	ACTO	ACNE		

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved bit field. Do not write any value.	R	0x0
7	CNI	Command not issue by Auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to Auto CMD12 error: ACEB, ACCE, ACTO or ACNE.  Read 0x0: Not error Read 0x1: Command not issued	R	0
6:5	Reserved	Reserved bit field. Do not write any value.	R	0x0
4	ACIE	Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable (MMChS.CMD[20] CICE bit).  Read 0x0: No error Read 0x1: Auto CMD12 Index Error	R	0
3	ACEB	Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response.  Read 0x0: No error Read 0x1: AutoCMD12 End bit Error	R	0
2	ACCE	Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the MMChS.CMD[19] CCCE bit.  Read 0x0: No error Read 0x1: Auto CMD12 CRC Error	R	0
1	ACTO	Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command.  Read 0x0: No error Read 0x1: Auto CMD12 Time Out	R	0
0	ACNE	Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before Auto CMD12 starts.  Read 0x0: Auto CMD12 Executed Read 0x1: Auto CMD12 Not Executed	R	0

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>														<b>Type</b>	<b>Reset</b>																																																										
31:27	Reserved	Reserved bit field. Do not write any value.														R	0x00																																																										
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal). Read 0x0: 1.8 V Not Supported Write 0x0: 1.8 V Not supported Read 0x1: 1.8 V Supported Write 0x1: 1.8 V Supported MMCHS1, 2 and 3: This bit must be set to 1.														RW	0																																																										
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal) Read 0x0: 3.0 V Not Supported Write 0x0: 3.0 V Not supported Read 0x1: 3.0 V Supported Write 0x1: 3.0 V Supported MMCHS1: This bit must be set to 1. MMCHS2 and 3: This bit must be left to 0.														RW	0																																																										
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal) Read 0x0: 3.3 V Not Supported Write 0x0: 3.3 V Not supported Read 0x1: 3.3 V Supported Write 0x1: 3.3 V Supported MMCHS1, 2 and 3: This bit must be left to 0.														RW	0																																																										
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality.														R	1																																																										
22	DS	DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported														R	1																																																										

Bits	Field Name	Description	Type	Reset
21	HSS	High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported	R	1
20:18	Reserved	Reserved bit field. Do not write any value.	R	0x0
17:16	MBL	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	Reserved	Reserved bit field. Do not write any value	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See <a href="#">Chapter 4, Power Reset and Clock Management</a> , for more information on the value of FUNC_96M_CLK clock signal.	R	0x00
7	TCU	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz	R	1
6	Reserved	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. <b>Note:</b> You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMcI.MMCHS_SYSCTL[15:6] CLKD bit field.	R	0x00

## **Memory Stick PRO Host Controller**

---

---

---

This chapter presents an overview of the Memory Stick PRO™ host controller in the OMAP34xx multimedia device.

<b>Topic</b>	<b>Page</b>
<b>23.1 Memory Stick PRO Host Controller Overview .....</b>	<b>3123</b>

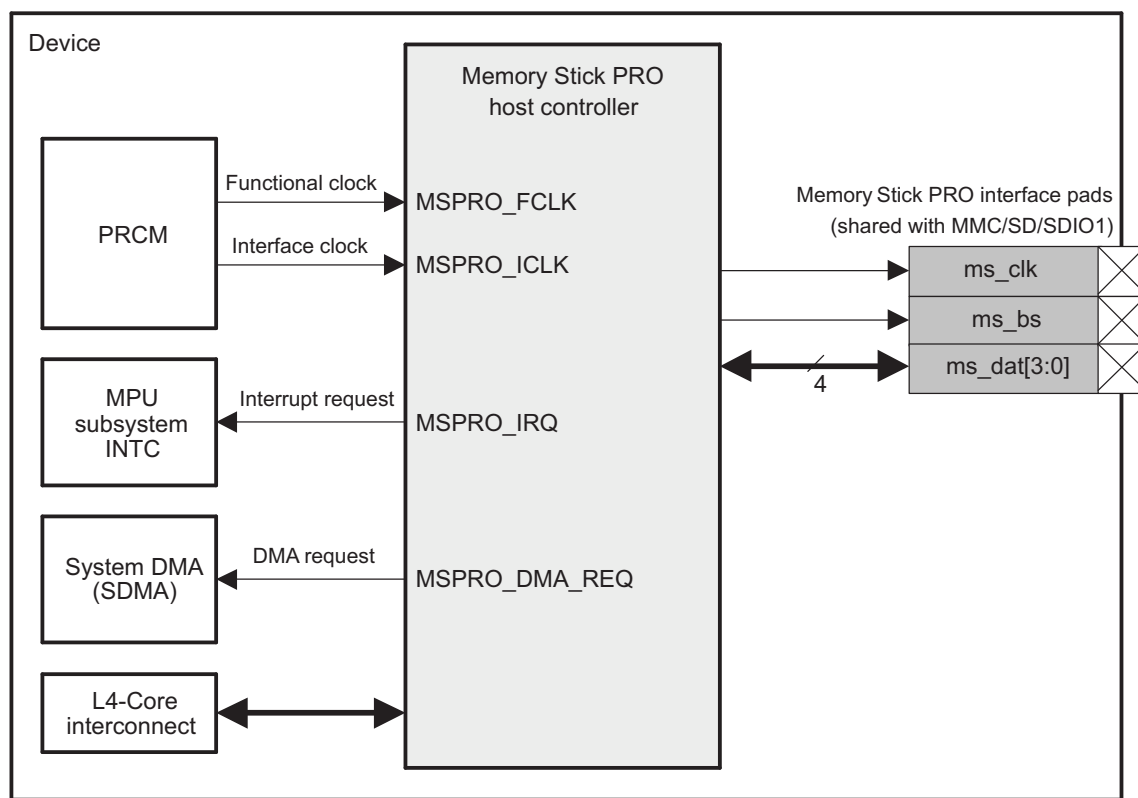

## 23.1 Memory Stick PRO Host Controller Overview

The Memory Stick PRO host controller provides the device with an interface between a microprocessor unit (MPU) local host (LH) and either a Memory Stick® or a Memory Stick PRO card.

The Memory Stick PRO host controller is connected to the L4-Core interconnect.

Figure 23-1 shows an overview of the Memory Stick PRO host controller.

**Figure 23-1. Memory Stick PRO Host Controller Overview**

MS-PRO-001

### 23.1.1 Main Features

The Memory Stick PRO host controller includes the following main features:

- Supports Memory Stick v1.x and Memory Stick PRO
- Data transmit/receive internal first-in first-out (FIFO) (64 bits x 4)
- Cyclic redundancy check (CRC) circuit
- Memory Stick serial clock (Memory Stick v1.x: 19.2 MHz; Memory Stick PRO: 32 MHz with 96-MHz functional clock source)
- Direct memory access (DMA) supported
- Lower 16-/32-bit access possible
- Little endian (internally big endian)
- L4 interconnect support

---

**Note:** Other information about Memory Stick PRO host controller are not available in the public domain.

---

# **High-Speed USB Host Subsystem and High-Speed USB OTG Controller**

---

---

---

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller of the OMAP34xx multimedia device.

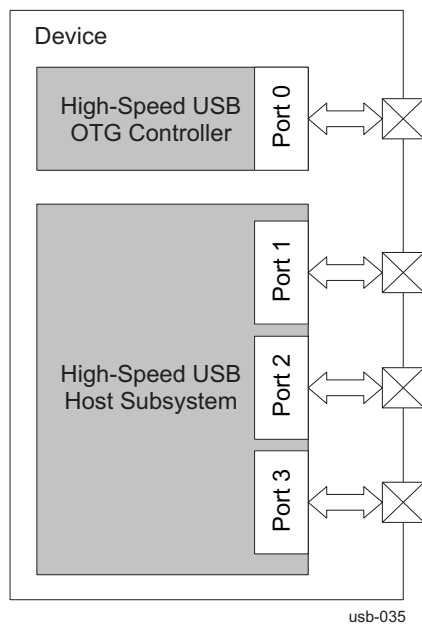

Topic	Page
<b>24.1 High-Speed USB OTG Controller .....</b>	<b>3126</b>
<b>24.2 High-Speed USB Host Subsystem .....</b>	<b>3147</b>

## Overview

The device contains two USB modules:

- A High-Speed USB OTG Controller (see [Section 24.1](#), *High-Speed USB OTG Controller*)
- A High-Speed USB Host Subsystem (see [Section 24.2](#), *High-Speed USB Host Subsystem*)

**Figure 24-1. USB Modules Overview**

## 24.1 High-Speed USB OTG Controller

**Note:** The High-Speed USB OTG Controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademarks of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

### 24.1.1 High-Speed USB OTG Controller Overview

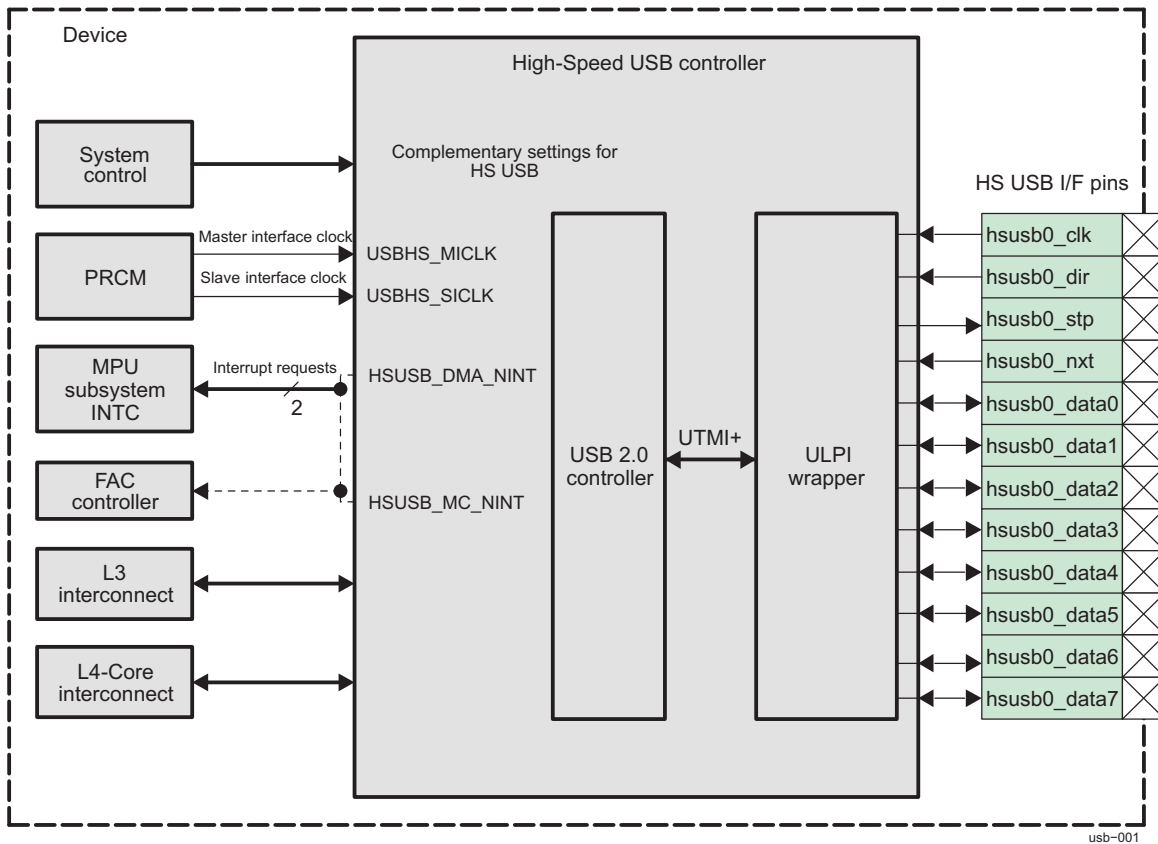

The OMAP34xx High-Speed USB controller is a high-speed, USB OTG dual-role-device (DRD) link controller supporting the following modes:

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP and SRP support.

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode).

Figure 24-2 highlights the high-speed USB controller.

Figure 24-2. High-Speed USB Controller Highlight

### 24.1.1.1 Main Features

The high-speed USB controller has the following features:

- Operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multipoint communications with other USB functions
- Complies with the USB 2.0 standard for high-speed (480 Mbps) functions and with the OTG supplement (Revision 1.0a)
- Includes all transfer types: Control, bulk, isochronous, interrupt
- Supports SRP and HNP
- Supports suspend/resume and remote wakeup
- Supports high-bandwidth isochronous and interrupt transfers
- Contains one PHY (physical layer) interface: ULPI interface (12/8-pin version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Each endpoint has its own FIFO, with the following properties:
  - Implemented within a single, 16K-byte internal RAM
  - Can be dynamically sized by software
  - Can be configured to hold multiple packets (up to 8192 bytes per FIFO)
  - Can be accessed either by direct access or by DMA controller
- Software connect/disconnect option for peripheral
- Performs all transaction scheduling in hardware

### 24.1.2 High-Speed USB OTG Controller Environment

Figure 24-3 shows a typical application using the high-speed USB controller.

Figure 24-3. High-Speed USB Controller Typical Application System

usb-002

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The current implementation of ULPI includes a method for manual, software-controlled generation of PHY-side register accesses supporting the following features:

- Access to vendor-specific or optional PHY-side registers
- CarKit operation (including interrupt, PHY-side registers)
- Access to vendor ID, product ID, scratch and debug registers

---

**Note:** In the carkit mode, the interface must connect to the TI TWL4030 companion chip for proper use.

---

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The TI high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface.

The 12-pin/8-bit data SDR ULPI interface is selected through the `USBOTG.OTG_INTERFSEL[1:0]` PHYSEL field and must be set to 0x1.

## 24.1.2.1 High-Speed USB Controller Functional Interfaces

### 24.1.2.1.1 Basic High-Speed USB Controller Pins

Figure 24-4 shows the high-speed USB controller functional interface.

**Figure 24-4. High-Speed USB Controller Functional Interface Signals**

### 24.1.2.1.2 High-Speed USB Controller Interface Description

Table 24-1 describes the I/O of the high-speed USB controller interface.

**Table 24-1. Input/Output Description**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
hsub0_clk	I	60-MHz clock input from ULPI PHY <sup>(2)</sup>	Unknown
hsub0_dir	I	Data direction control from ULPI PHY	Unknown
hsub0_stp	O	Stop signal to ULPI PHY	1
hsub0_nxt	I	Next signal from ULPI PHY	Unknown
hsub0_data0	I/O	Bidirectional DATA0	Unknown
hsub0_data1	I/O	Bidirectional DATA1	Unknown
hsub0_data2	I/O	Bidirectional DATA2	Unknown
hsub0_data3	I/O	Bidirectional DATA3	Unknown
hsub0_data4	I/O	Bidirectional DATA4	Unknown
hsub0_data5	I/O	Bidirectional DATA5	Unknown
hsub0_data6	I/O	Bidirectional DATA6	Unknown
hsub0_data7	I/O	Bidirectional DATA7	Unknown

<sup>(1)</sup> I = Input; O = Output

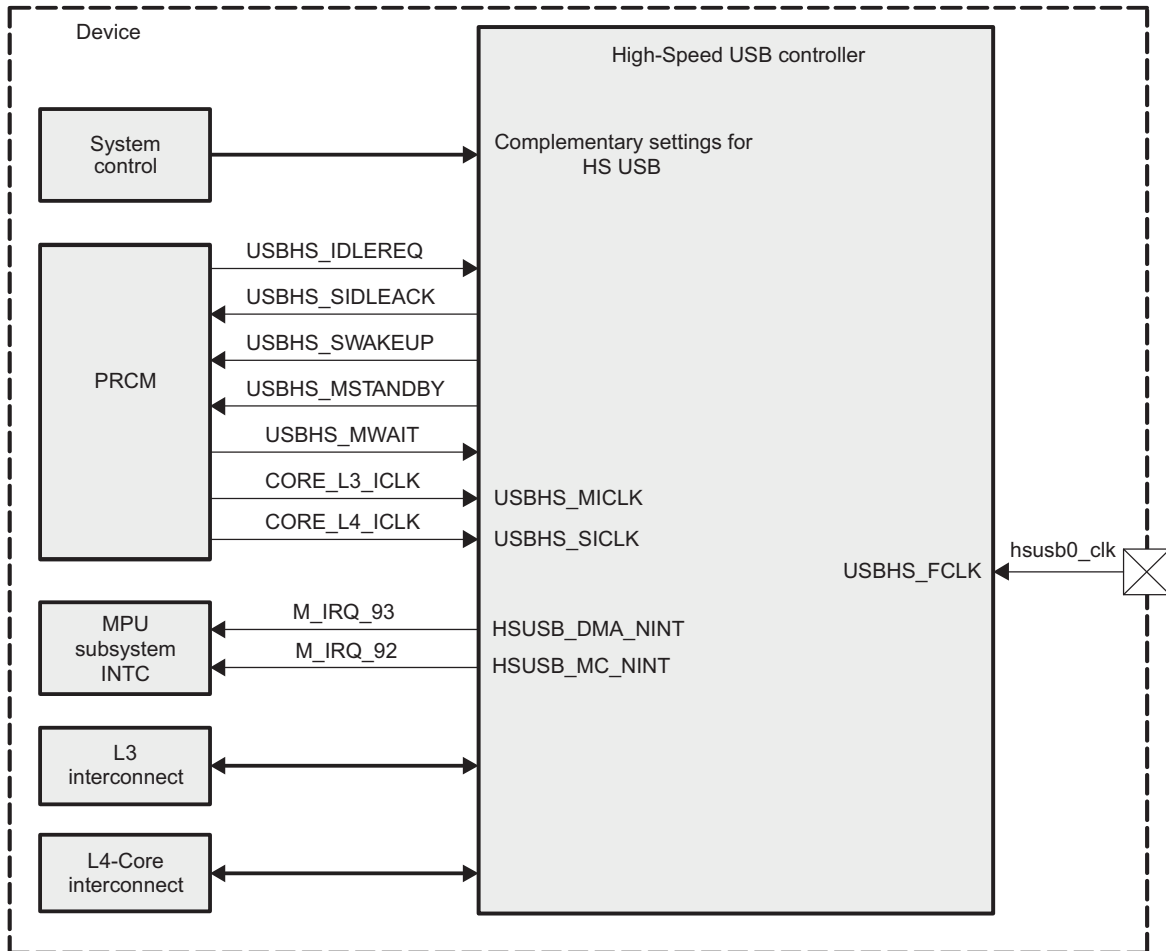

<sup>(2)</sup> This signal is also used as re-timing input.

### 24.1.3 High-Speed USB OTG Controller Integration

The high-speed USB controller is connected to L3 interconnect master (initiator) and slave (target) interfaces and L4-Core interconnect. The L3 interconnect generates data traffic within the OMAP34xx device. The L4-Core interconnect is a configuration port for register setting.

Figure 24-5 highlights the high-speed USB controller integration in the OMAP34xx device.

Figure 24-5. High-Speed USB Controller Integration

usb-004

#### 24.1.3.1 Clocking, Reset, and Power-Management Scheme

##### 24.1.3.1.1 Clocks

##### 24.1.3.1.1.1 Module Clocks

Three clocks are provided to the high-speed USB controller, as shown in Table 24-2.

Table 24-2. USB Clocks

Attributes	Frequency	Name	Mapping	Comments
Functional clock	60 MHz	USBHS_FCLK	hsub0_clk	Source is external transceiver (ULPI)
Master Interface clock	Depending on PRCM register settings	USBHS_MICLK	CORE_L3_ICLK	Source is PRCM module

**Table 24-2. USB Clocks (continued)**

Attributes	Frequency	Name	Mapping	Comments
Slave Interface clock	Depending on PRCM register settings	USBHS_SICLK	CORE_L4_ICLK	Source is PRCM module

#### 24.1.3.1.1.2 Master Interface Clock

The master interface clock USBHS\_MICLK comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM\_ICLKEN1\_CORE[4]:

- 0: Disabled
- 1: Enabled

and PRCM.CM\_AUTOIDLE1\_CORE[4] (enables/disables automatic control of the interface clock)—see [Table 24-3](#).

**Table 24-3. High-Speed USB Interface Clock**

PRCM.CM_AUTOIDLE1_CORE[4]	PRCM.CM_ICLKEN1_CORE[4]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

#### 24.1.3.1.1.3 Functional Clock

The functional clock (60MHz), USBHS\_FCLK, comes from the external ULPI transceiver through the hsub0\_clk input pin.

#### 24.1.3.1.2 Resets

The high-speed USB controller can be reset either by the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in the module.

##### 24.1.3.1.2.1 Hardware Reset

The high-speed USB controller is attached to the CORE power domain: The CORE\_RST signal resets the module (see [Chapter 4, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the high-speed USB controller.

##### 24.1.3.1.2.2 Software Reset

The high-speed USB controller has a software reset through the USBOTG.OTG\_SYSCONFIG[1] SOFTRESET bit (0: Normal mode, 1: Module is reset).

This bit controls the software reset. Writing 1 to this bit resets the module. The bit value 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

#### 24.1.3.1.3 Power-Management Scheme

##### 24.1.3.1.3.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB functional clock (60 MHz), USBHS\_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

#### 24.1.3.1.3.2 System Power Management

##### Master Interface Power Management

The high-speed USB controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB controller has a MSTANDBY handshake mechanism with the PRCM module (see [Figure 24-5](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field.

- Smart standby

The high-speed USB controller is configured in smart-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force standby

The high-speed USB controller is configured in force-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).

- When the high-speed USB controller operates as a host: The USBOTG.POWER[1] SUSPENDMODE bit is set to 1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. The USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to assert MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
  - Remote wakeup causes a RESUME interrupt
  - Set the USBOTG.POWER[3] RESET bit to 1.
  - Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit.

OR

  - Set the USBOTG.POWER[3] RESET bit to 1.
  - Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit.
- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. The USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to enable the MSTANDBY signal. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
  - Set the USBOTG.POWER[2] RESUME bit to 1.

- Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit.  
OR
- RESET interrupt is generated by the high-speed USB controller.
- Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No standby  
The high-speed USB controller is configured in no-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 24-4 describes the high-speed USB master interface power management modes.

**Table 24-4. High-Speed USB Master Interface Power Management Modes**

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE Field
Force-standby	0x0
No-standby	0x1
Smart-standby	0x2
Reserved	0x3

### Slave Interface Power Management

The high-speed USB controller can be configured through the USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS\_ICLK is disabled (PRCM register bit PRCM.CM\_ICLKEN1\_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM\_ICLKEN1\_CORE[4] and PRCM.CM\_AUTOIDLE1\_CORE[4] both set to 1)
- L4 interface clock idle transitions:

Configured in smart-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from idle mode if the USBOTG.OTG\_SYSCONFIG[2] ENABLEWAKEUP bit is set to 1 (wake-up capability enabled) and the PRCM register bit PRCM.PM\_WKEN1\_CORE[4] is also set to 1.

- Force-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS\_ICLK is disabled (PRCM register bit PRCM.CM\_ICLKEN1\_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM\_ICLKEN1\_CORE[4] and PRCM.CM\_AUTOIDLE1\_CORE[4] both set to 1)
- The L4 interface clock idle transitions:

Configured in force-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.

- No-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock(s) USBHS\_ICLK are disabled (PRCM register bit PRCM.CM\_ICLKEN1\_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM\_ICLKEN1\_CORE[4] and PRCM.CM\_AUTOIDLE1\_CORE[4] both set to 1)
- L4 interface clock idle transitions  
Configured in no-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

Table 24-5 describes the high-speed USB slave interface power management modes.

**Table 24-5. High-Speed USB Slave Interface Power Management Modes**

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE Field
Force-idle	0x0
No-idle	0x1
Smart-idle	0x2
Reserved	0x3

**Note:** The high-speed USB controller standby status can be checked by the PRCM module register bit CM\_IDLEST1\_CORE[4].

- 0: High-Speed USB is active.
- 1: High-Speed USB is in standby mode.

The high-speed USB controller wake-up status can be checked by the PRCM module register bit PM\_WKST1\_CORE[4].

- Read 0: Wakeup has not occurred or was masked.
- Read 1: Wakeup has occurred.
- Write 0: Status bit unchanged.
- Write 1: Status bit is cleared to 0.

#### 24.1.3.1.3.3 Local Power Management

The high-speed USB controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

#### 24.1.3.1.4 Power Domain

The high-speed USB controller is attached to the CORE power domain (see [Chapter 4, Power, Reset, and Clock Management](#)).

### 24.1.3.2 Hardware Requests

#### 24.1.3.2.1 Interrupt Requests

Table 24-6 lists the interrupt lines that are driven out from the high-speed USB controller to the MPU subsystem INTC.

**Table 24-6. High-Speed USB Interrupts**

<b>Name</b>	<b>Mapping</b>	<b>Comments</b>
<b>HS USB Controller Interrupt</b>		
HSUSB_MC_NINT	M_IRQ_92	Destination is MPU subsystem interrupt controller
<b>HS USB DMA Controller Interrupt</b>		
HSUSB_DMA_NINT	M_IRQ_93	Destination is MPU subsystem interrupt controller

**24.1.3.2.2 IDLE Handshake Protocol**

The PRCM handles an IDLE handshake protocol for the high-speed USB controller. The IDLE handshake protocol allows the PRCM requiring the high-speed USB controller to enter idle mode. The high-speed USB controller acknowledges when it is ready.

**24.1.3.2.3 MSTANDBY Handshake Protocol**

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

**24.1.3.2.4 Wake-Up Request**

The high-speed USB controller generates a wake-up request signal (UBSHS\_SWAKEUP) to the PRCM module.

## 24.1.4 High-Speed USB OTG Controller Functional Description

### 24.1.4.1 Inventra™ MUSBMHDC

The core functionality of the module is provided by a third-party IP, the Inventra MUSBMHDC from Mentor Graphics Corporation.

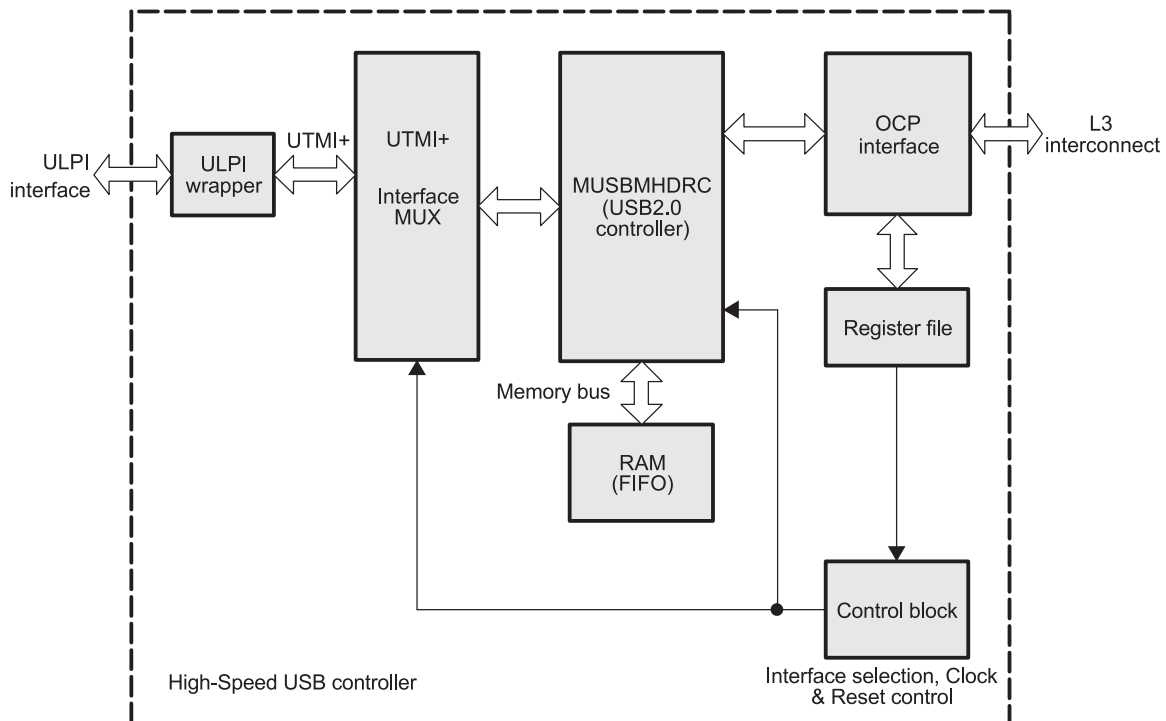

The high-speed USB controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB controller includes the following:

- MUSBMHDC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Built-in self-test (BIST) controller
- Two memories (total of 16Kbytes; available for various endpoints)
- Reset and clock generation
- DFT compliance with regards to latest specs

Figure 24-6 shows the high-speed USB controller.

Figure 24-6. High-Speed USB Controller

usb-005

### 24.1.4.2 Configuration

The Mentor Graphics IP RTL MUSBMHDCR can be configured to generate some customized hardware. Those options are all hard-wired and cannot be reprogrammed in the case of the TI High-Speed USB controller.

The following options are selected:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16K bytes RAM buffer
- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

### 24.1.4.3 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets—interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed:

#### 24.1.4.3.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, the DMA controller, and the individual endpoints.

The specific items of a configuration are for each endpoint:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

---

**Note:** On the system level, it must be ensured that the reset and the interface are selected before the 60-MHz functional clock (USBHS\_FCLK) is applied to the module. Correct functionality is not ensured if either a reset deassertion or a change in the interface selection occurs when the functional clock USBHS\_FCLK is already running.

---

#### 24.1.4.3.1.1 MSTANDBY Deassertion

MSTANDBY is asserted during reset and continues to be 1 after reset. The high-speed USB controller does not perform master interface transactions until this signal is deasserted. Firmware must follow these steps to begin normal operations on the master interface bus:

- Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit.
- Put the high-speed USB controller into no-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x1) and no-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDLEMODE field = 0x1).

Even though ENABLEFORCE is 0, MSTANDBY remains asserted until the high-speed USB controller core is out of idle state.

#### 24.1.4.3.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

#### 24.1.4.4 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

##### 24.1.4.4.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16K bytes, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

##### 24.1.4.4.2 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs.

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

#### 24.1.4.4.2.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

#### 24.1.4.4.2.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

#### 24.1.4.4.2.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable
- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller uses burst transfers on the L3 interconnect. DMA transfers can be 8-bit, 16-bit, or 32-bit as required. However, all transfers associated with one packet (except the last packet) must be of the same width so that the data is consistently byte-, word-, or double-word-aligned. The last transfer can contain fewer bytes than the previous transfer to complete an odd-byte or odd-word transfer.

#### 24.1.4.5 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

#### 24.1.4.6 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3 x 1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3 x 1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

### 24.1.5 High-Speed USB OTG Controller Basic Programming Model

This section describes only the TI-specific programming model details.

#### 24.1.5.1 High-Speed USB Controller Interface Selection

The TI High-Speed USB controller supports only the 12-pin/8-bit data version ULPI interface (see [Table 24-15](#)).

The 8-pin, 4-bit version ULPI interface and 8-bit UTMI+ Level 3 interface are not supported.

The 12-pin/8-bit data SDR ULPI interface is selected through the USBOTG.OTG\_INTERFSEL[1:0] PHYSEL field set to 0x1.

#### 24.1.5.2 Enable Simulation Acceleration Features

The USBOTG.OTG\_SIMENABLE register is dedicated solely for simulation (see [Table 24-17](#)) and is used to reduce timer length and, hence, the time taken for the test bench to run.

This special mode can be active only during simulation and must be disabled for normal operation. The firmware must keep TM1 inactive (reset value) during normal operation. An accidental write to this register can cause a malfunction.

#### 24.1.5.3 Enabling MSTANDBY in Force-Standby Mode

The USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit controls MSTANDBY behavior in force-standby mode only (see [Table 24-19](#)). In this mode, only when the internal core is idle (the module has no activity; that is, the USB is in suspend state) and when 1 is written to this bit, MSTANDBY goes high. Similarly, when ENABLEFORCE is 0 and the internal core is also in a non-idle state, MSTANDBY is deasserted. This bit does not influence MSTANDBY behavior in all other modes, such as no-standby and smart-standby.

#### 24.1.5.4 Power Management Basic Programming Model

This section describes the settings for optimal High-Speed USB controller power management, depending on the use of this module in the application.

Two registers are involved in power management: USBOTG.OTG\_SYSCONFIG and USBOTG.OTG\_FORCESTDBY.

On reset, the high-speed USB controller has the following configuration:

- Master interface power management is in force-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is disabled (USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit = 0).

- MSTANDBY signal assertion is enabled (USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit = 1).

#### 24.1.5.4.1 High-Speed USB Controller Not Used for Application

In this scenario, the high-speed USB controller is not used by the system software. Default settings must be changed to reduce power consumption. Enabling the internal clock autogating feature cuts off the module internal interface clock as soon as it is no longer required. This is done by setting the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 1.

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

- Master interface power management is in force-standby mode (USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is enabled (USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit = 1).
- MSTANDBY signal assertion enabled (USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit = 1)

#### 24.1.5.4.2 High-Speed USB Controller in Host Mode

When used as a host, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby and smart-idle modes.
2. Set the USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

---

**Note:** The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

---

#### 24.1.5.4.3 High-Speed USB Controller in Peripheral Mode

When used as a peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming the smart-idle mode..
3. Set the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

**Note:** The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

---

#### 24.1.5.4.4 High-Speed USB Controller in Host/Peripheral Mode

When used as a host/peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

See [Section 24.1.5.4.2](#) and [Section 24.1.5.4.3](#) for the programming sequence.

As an application required to disable the master interface, the high-speed USB controller can also be programmed as follows:

- Master interface power management in force-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion enabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG\_SYSCONFIG[13:12] MIDDLEMODE field to 0x0, the USBOTG.OTG\_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 0 to program the force-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG\_FORCESTDBY[0] ENABLEFORCE bit to 1 to enable the MSTANDBY assertion before enabling internal clock autogating feature.
4. Set the USBOTG.OTG\_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

---

**Note:** The internal clock the autogating feature and smart-idle mode must not be programmed simultaneously.

---

### 24.1.6 High-Speed USB OTG Controller Register Manual

As this chapter describes only the TI-specific details, this section presents only the TI-specific registers of the high-speed USB controller.

Table 24-7 lists the base address and address space for the high-speed USB controller.

**Table 24-7. High-Speed USB Controller Instance Summary**

Module Name	Base Address	Size
USBHS	0x480A B000	4K bytes

#### CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

#### 24.1.6.1 High-Speed USB Register Mapping Summary

Table 24-8 lists the TI-specific High-Speed USB controller registers.

**Table 24-8. TI-Specific High-Speed USB Controller Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	USBHS Physical Address

### 24.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

Each of the three external ports is owned by exactly one of the controllers at any time.

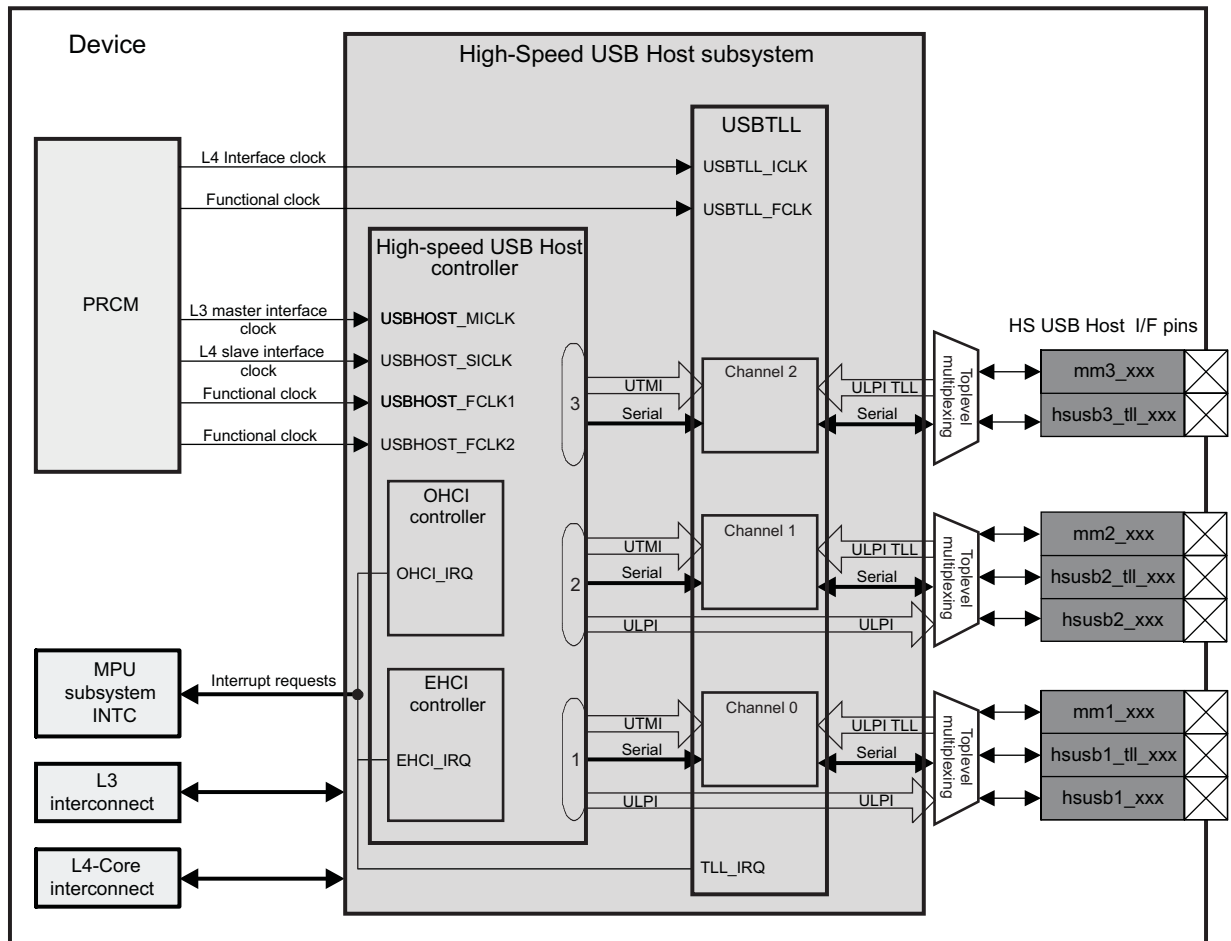

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external-to-OMAP chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

[Figure 24-7](#) highlights the high-speed USB host subsystem.

Figure 24-7. High-Speed USB Host Subsystem Highlight

usb-007

### 24.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- Multiport high-speed USB host controller:
  - Complies with the USB 2.0 standard for high-speed (480 Mbps) functions
  - USB 2.0 low-speed (1.5M bit/s), full-speed (12M bit/s), and high-speed (480M bit/s) operations
  - Three downstream ports (3-port root hub)
  - Complies with EHCI (high-speed host controller)
  - Complies with OHCI (low-speed/full-speed host controller)
  - Supports suspend/resume and remote wakeup
  - Interface with USBTLL port A on all ports (UTMI+)
    - 8-bit datapath
    - 60-MHz synchronous (on-chip) interface
  - Interface with ULPI PHYs (transceivers) on all ports (only two mapped)
    - 12-pin/8-bit data single data rate (SDR) mode
    - 60-MHz clock, generated by the host: ULPI "input" clocking mode

**CAUTION**

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY)

- Hardware-driven save-and-restore of the suspended host hardware context
- Two interrupt lines
- USBTLL module
  - Three channels
  - Three ports (A, C, and D) by channel
  - Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI “local” port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, “remote” ports).
    - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
    - 8-data-bit, 60-MHz UTMI (HS/FS/LS-capable)
    - UTMI+ Level 3 extensions
    - Vcontrol/Vstatus (from UTMI)
    - Serial FS/LS “6-pin” mode
  - Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
    - SDR and dual data rate (DDR) ULPI capable (resp 8/4-bit data width modes)
    - Supports optional 6-pin/3-pin serial modes
    - Supports optional input clocking mode
  - Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
    - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
    - All modes are supported for TLL or PHY interface configuration.
    - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
  - An interrupt line
- USB port signal pins interface supporting:
  - External USB transceivers
    - ULPI interface: 12-pin/8-bit data SDR version
    - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
  - TLL mode
    - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
    - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

**Table 24-21. USB Connectivity Modes**

USB Connectivity Modes	Port 1	Port 2	Port 3
ULPI interface	√	√	
Serial 6-pin transceiver interfaces	√	√	√
ULPI TLL interfaces	√	√	√
Serial 6-pin TLL interfaces	√	√	√

**Note:** Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

## 24.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

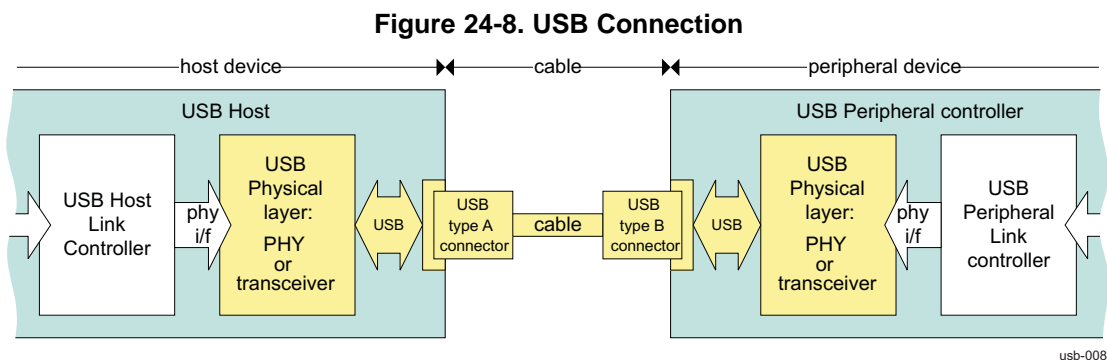

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
  - ULPI interface: 12-pin/8-bit data SDR version
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
  - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

### 24.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in [Figure 24-8](#).

The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

### 24.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

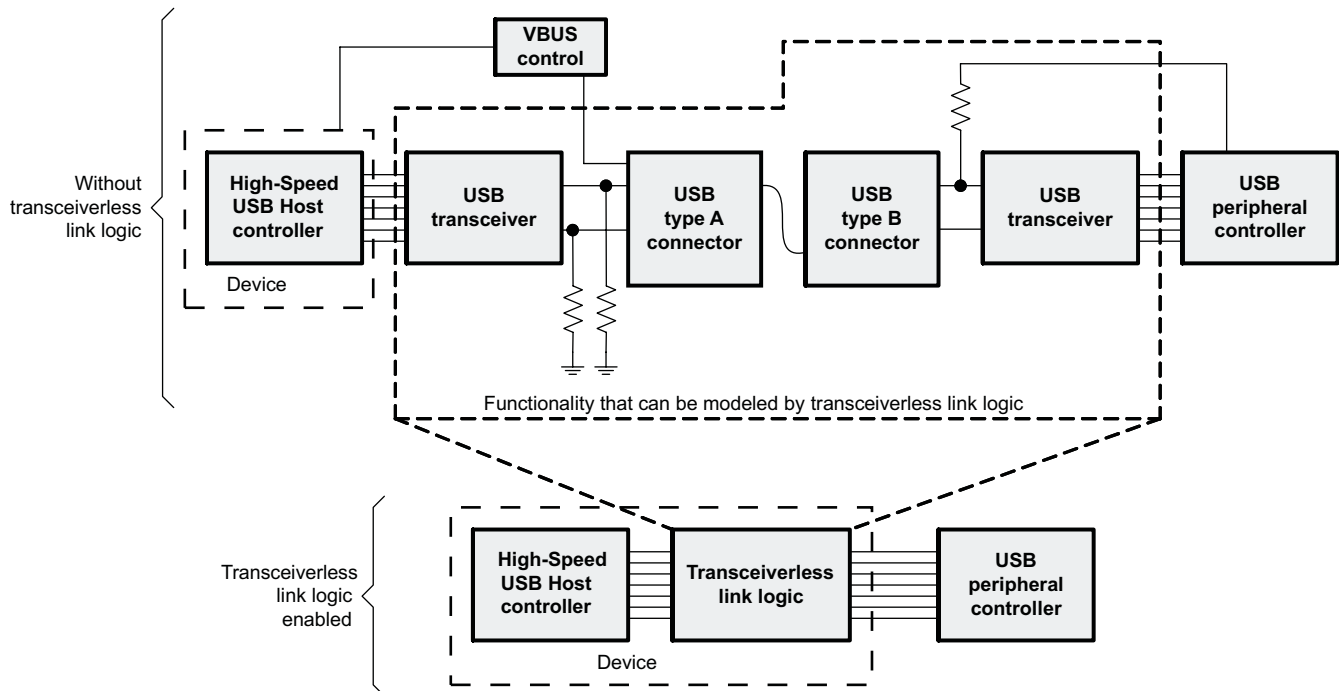

The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 24-9 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 24-9 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

**Figure 24-9. High-Speed USB Host Controller Connection—With and Without TLL**

usb-009

**Note:** The USB bus lines (D+/D-) no longer appear in subsequent figures: They are emulated by the TLL.

### 24.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

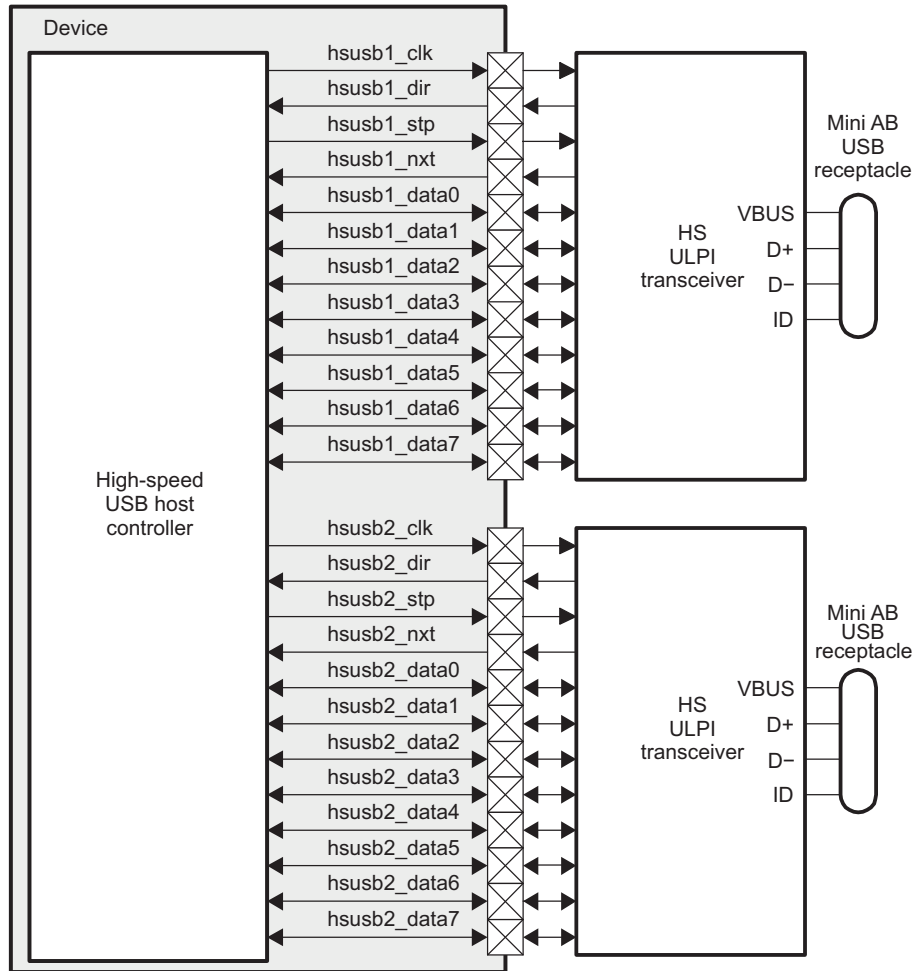

- External USB transceiver
  - ULPI interfaces: 12-pin/8-bit data SDR version
- TLL
  - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high- and full-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. A mini A-B external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

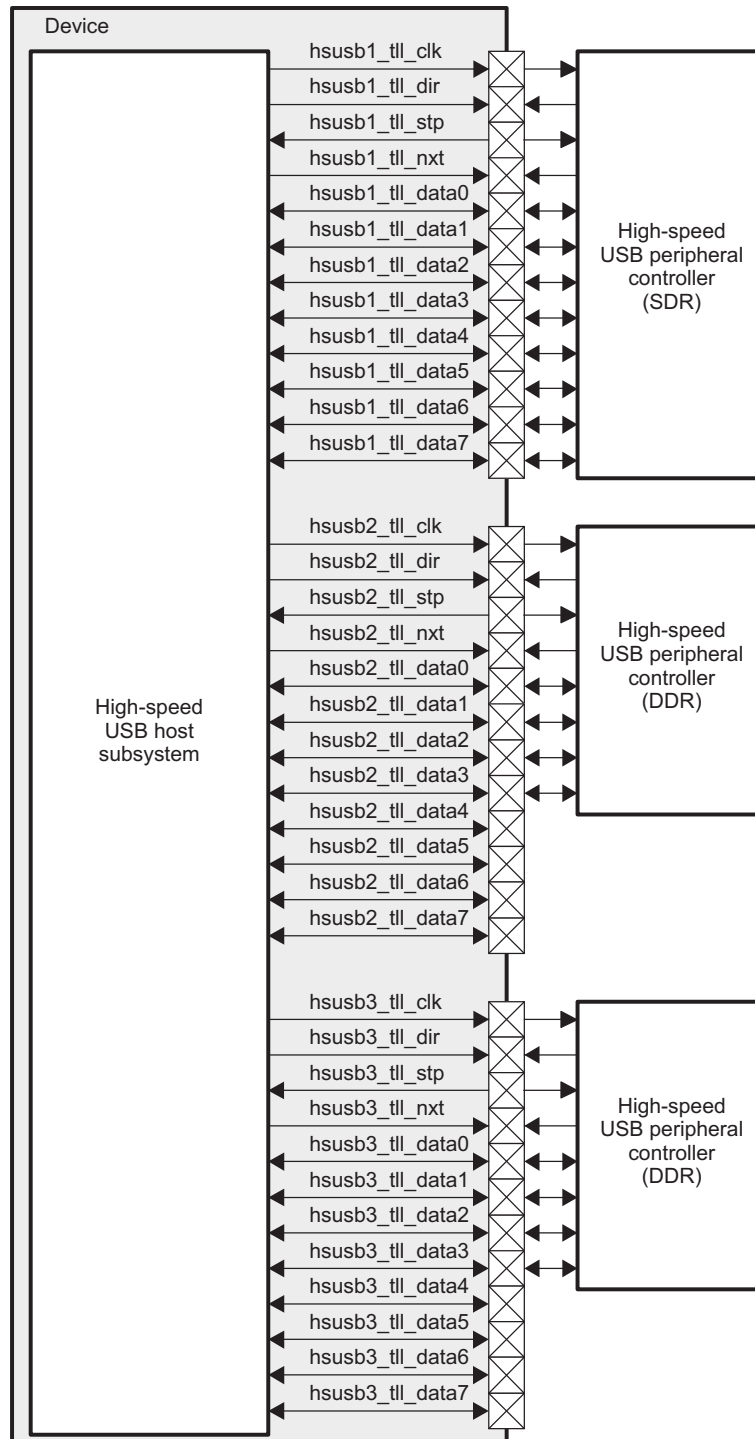

Figure 24-10 and Figure 24-11 show typical applications using the high-speed USB host subsystem with the ULPI, and the ULPI TLL, respectively.

**Figure 24-10. High-Speed USB Host Controller Typical Application System – ULPI Interfaces**

ULPI Interfaces - USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers

usb-010

**Figure 24-11. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces**

ULPI TLL Interfaces -The high-speed USB host controller is coupled with the USBTLL module to compose the ULPITLL interface modes usb-032

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

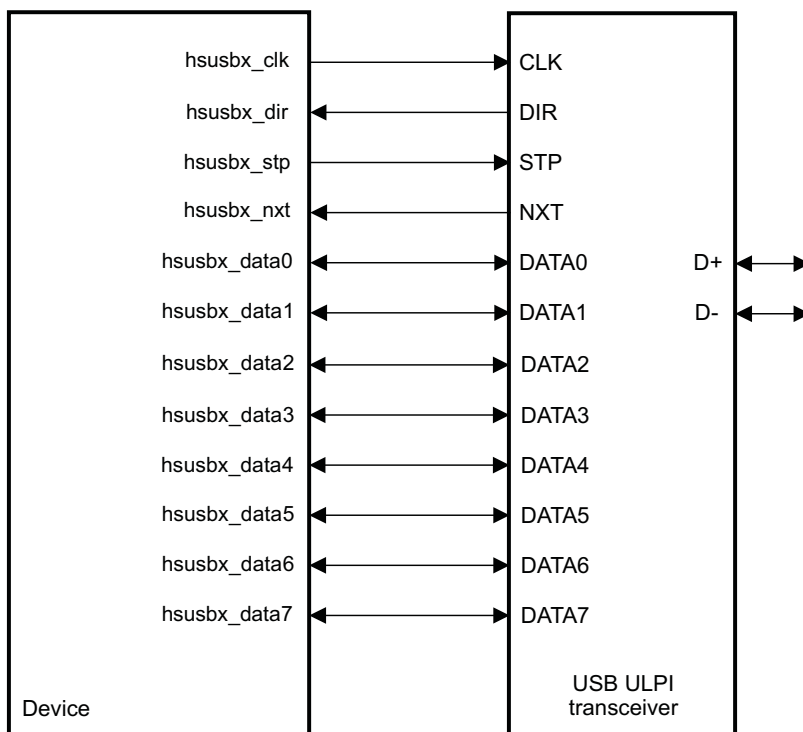

### 24.2.2.3.1 Transceiver Interface Configurations

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

**Note:** In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

Figure 24-12 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

**Figure 24-12. ULPI Interfaces – 12-Pin/8-Bit Data SDR Version**

x is the USB port number (1 or 2)

usb-011

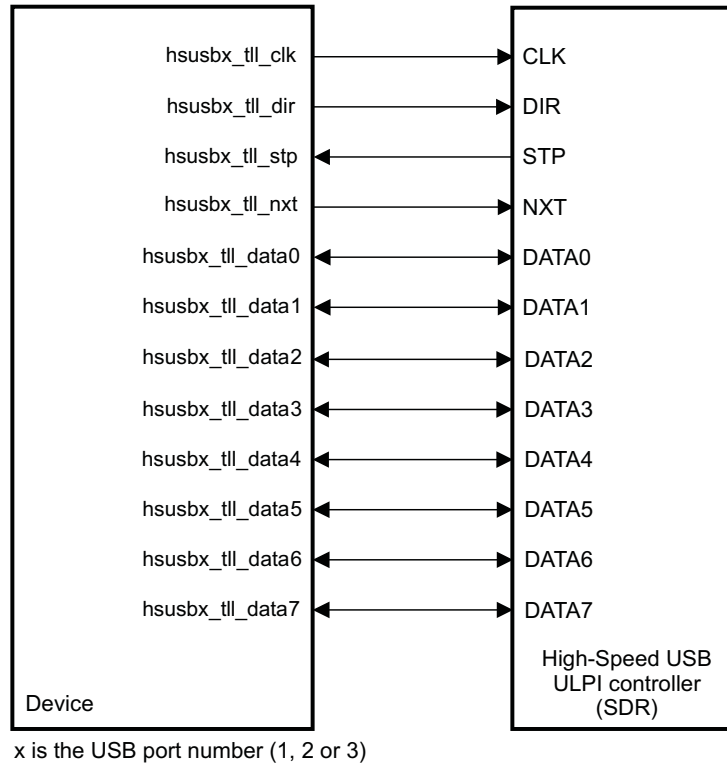

### 24.2.2.3.2 TLL Configurations

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host subsystem supports the 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions of the ULPI TLL interface mode.

Figure 24-13 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

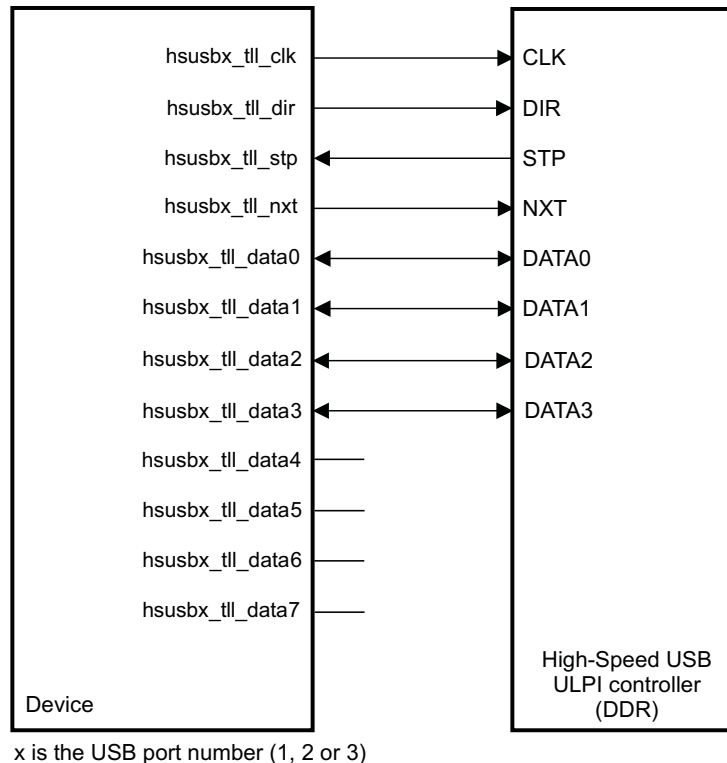

**Figure 24-13. ULPI TLL Interfaces –12-Pin/8-Bit Data SDR Version**

usb-012

Figure 24-14 shows USB ports using the 8-pin/4-bit data DDR version of the ULPI TLL interface mode.

**Figure 24-14. ULPI TLL Interfaces – 8-Pin/4-Bit Data DDR Version**

hsusb3_tll_data7	I/O	Bidirectional DATA7	0

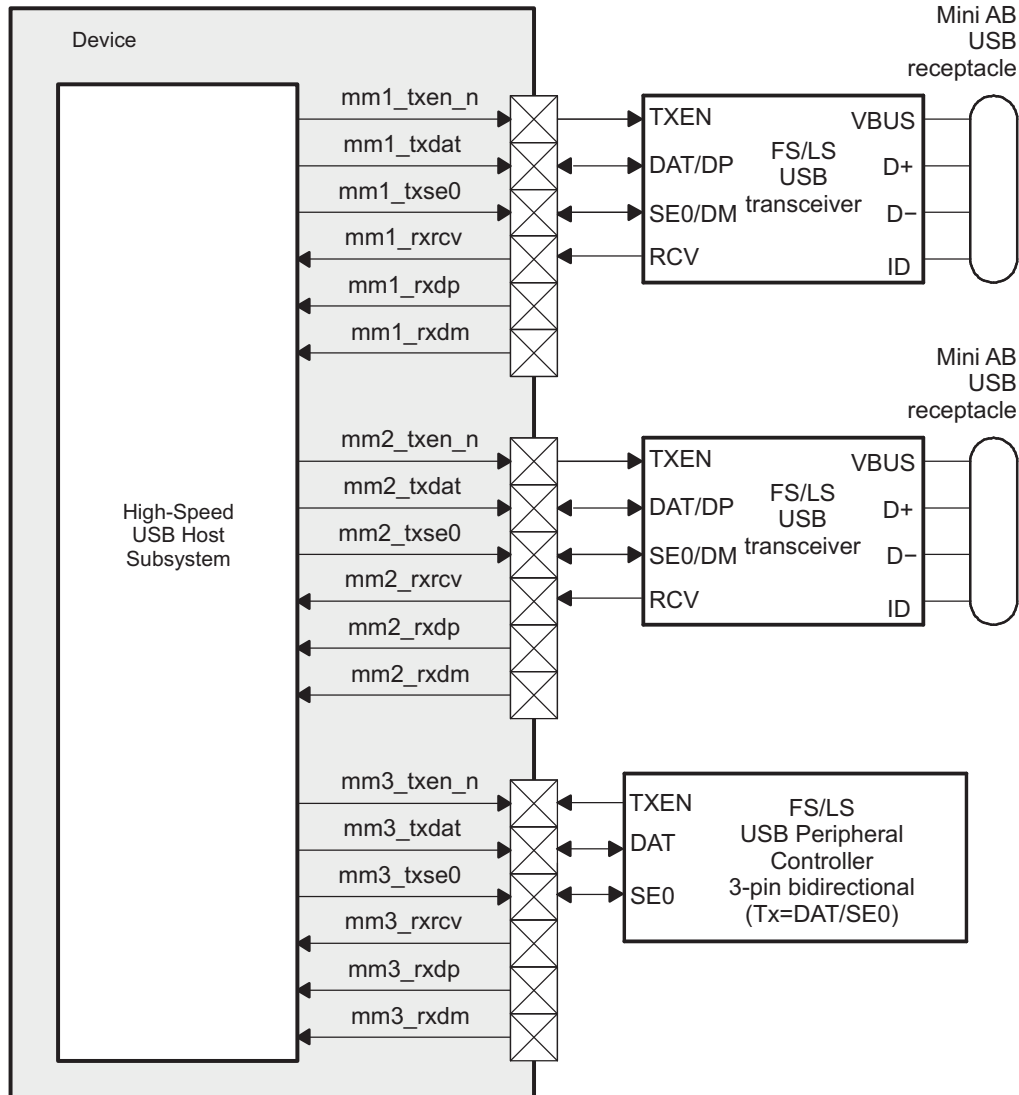

ULPI (PHY) Interfaces and ULPI TLL Interfaces can not be used together: Either the ULPI (PHY) Interfaces or the ULPI TLL Interfaces are selected.

#### 24.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 24-16 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

**Figure 24-16. High-Speed USB Host Subsystem Typical Application System**

usb-015

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

**CAUTION**

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

### CAUTION

It is possible to change the polarity of the TXEN signal for each USB port using the following bits:

- CONTROL.[CONTROL\\_WKUP\\_CTRL](#)[2]  
M\_FSUSB3\_TXEN\_N\_OUT\_POLARITY\_CTRL
- CONTROL.[CONTROL\\_WKUP\\_CTRL](#)[1]MM\_FSUSB3\_TXEN\_N\_OUT\_POLARITY\_CTRL
- CONTROL.[CONTROL\\_WKUP\\_CTRL](#)[0]  
M\_FSUSB3\_TXEN\_N\_OUT\_POLARITY\_CTRL

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

#### 24.2.2.4.1 Encoding in Serial Mode

##### 24.2.2.4.1.1 Unidirectional

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 24-23](#) is used.

**Table 24-23. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description																									
TXEN	Output	Input	When low or high (depending on the CONTROL. <a href="#">CONTROL_WKUP_CTRL</a> [2, 1, and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit), the USB transceiver drives D+ and D-.																									
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low/high; ignored when TXEN is high/low (depending on the TXEN signal polarity; see CONTROL. <a href="#">CONTROL_WKUP_CTRL</a> [2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit).																									
			<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th>TXEN</th> <th>DAT</th> <th>SE0</th> <th>D+</th> <th>D-</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>0</td> <td>1</td> </tr> <tr> <td></td> <td>1</td> <td>0</td> <td>1</td> <td>0</td> </tr> <tr> <td></td> <td>X</td> <td>1</td> <td>0</td> <td>0</td> </tr> <tr> <td>1</td> <td>X</td> <td>X</td> <td>Undriven</td> <td>Undriven</td> </tr> </tbody> </table>	TXEN	DAT	SE0	D+	D-	0	0	0	0	1		1	0	1	0		X	1	0	0	1	X	X	Undriven	Undriven

			0	0			
1	1						

#### 24.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 24-25](#) is used.

**Table 24-25. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
TXEN	Output	Input	When low or high (depending on the CONTROL. <a href="#">CONTROL_WKUP_CTRL</a> [2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit), the USB transceiver drives D+ and D-.

**Table 24-25. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
DAT and SE0	Output	Input	When TXEN is low/high (depending on the TXEN signal polarity; see the CONTROL.CONTROL_WKUP_CTRL[2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit), the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.				
			TXEN	DAT	SE0	D+	D-
				0	0	0	0
	1	0		1	0	0	
	Input	Output	TXEN	D+	D-	DAT	SE0
				0	0	0	1
				0	1	0	0
				1	0	1	0
				1	1	Undefined	Undefined

**Note:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 24-26](#) is used.

**Table 24-26. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
TXEN	Output	Input	When low or high (depending on the CONTROL.CONTROL_WKUP_CTRL[2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTRL bit), the USB transceiver drives D+ and D-.		
DM			Value driven to or received from D-

			0	0	0
			0	1	1
	Input	Output	TXEN	D+	DP
			1	0	0
			1	1	1

**Table 24-26. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
RCV	Input	Output	Output from transceiver single-ended D- signal receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
1	1	X			

**Note:** The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

#### 24.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I2C, UART, etc.)

Figure 24-17 and Figure 24-18 show system integration for sideband signals for two logically identical USB connections: One in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 24-17 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in Section 24.2.4.2.4.1.1.

**Figure 24-17. Serial Interface Sideband Integration - Transceiver Configuration**

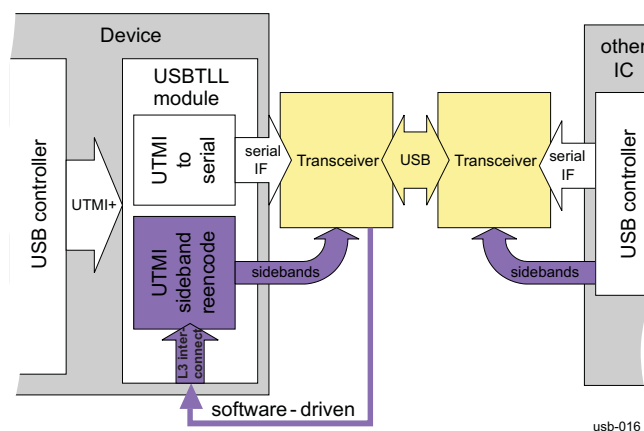

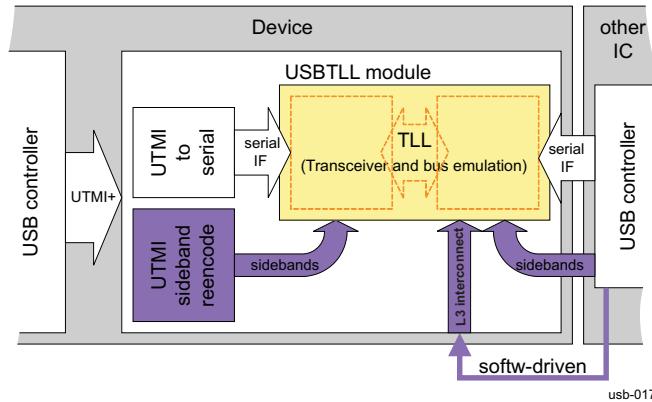

Figure 24-18 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
  - Sideband input signals at the TLL module boundary (tllpuen, tlldrvbus, tllbusvalid, etc.)
  - The software-driven VBUS control procedure is described in [Section 24.2.4.2.4.2.2](#)

**Figure 24-18. Serial Interface Sideband Integration - TLL Configuration**

#### 24.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I<sup>2</sup>C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

##### 24.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

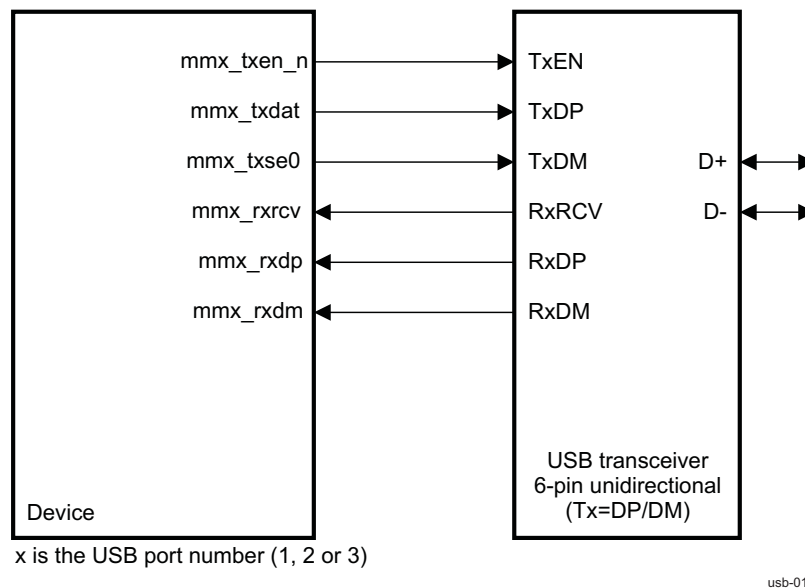

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 24-23](#) is used.

Figure 24-19 shows a USB port using DAT/SE0 encoding.

**Figure 24-19. 6-Pin Unidirectional Using DAT/SE0 Signaling**

When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 24-24](#) is used.

[Figure 24-20](#) shows a USB port using DP/DM encoding.

**Figure 24-20. 6-Pin Unidirectional Using DP/DM Signaling**

#### 24.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

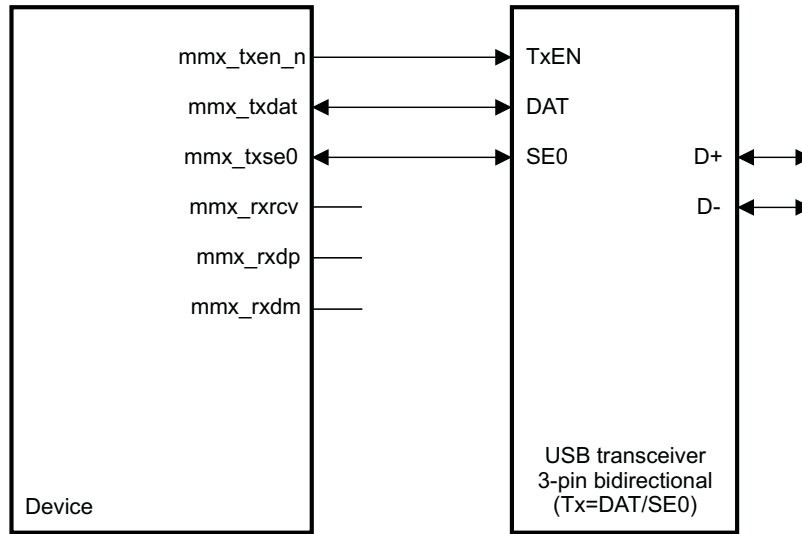

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 24-25](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

**Note:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

Figure 24-21 shows a USB port using DAT/SE0 encoding.

**Figure 24-21. 3-Pin Bidirectional Using DAT/SE0 Signaling**

x is the USB port number (1, 2 or 3)

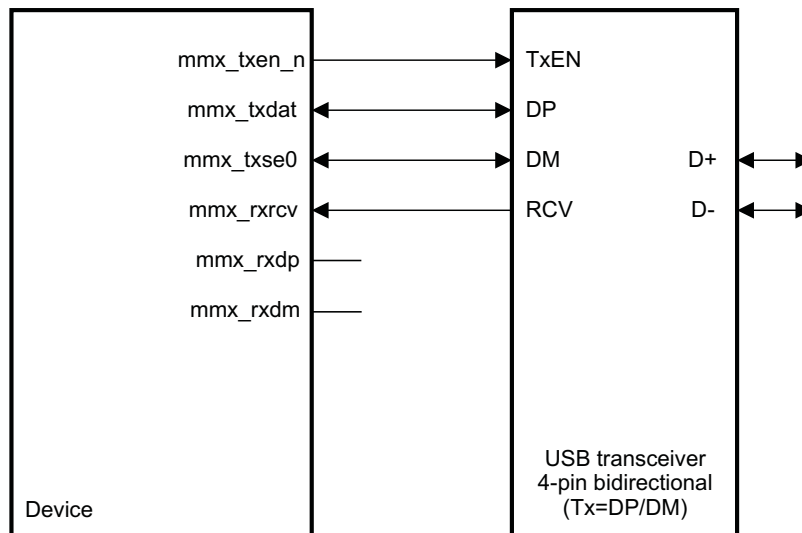

usb-020

The signaling listed in Table 24-26 is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

**Note:** The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 24-22 shows a USB port using DP/DM encoding.

**Figure 24-22. 4-Pin Bidirectional Using DP/DM Signaling**

x is the USB port number (1, 2 or 3)

108-021

#### 24.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

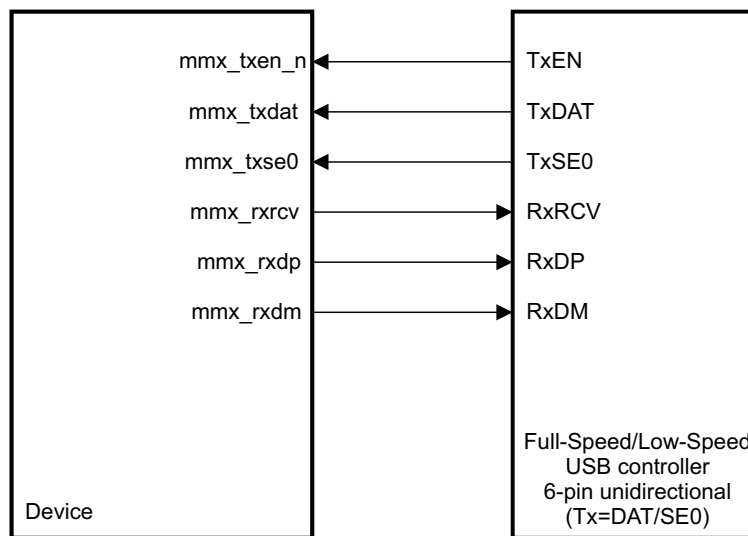

##### 24.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 24-23 shows an external device using DAT/SE0 encoding.

**Figure 24-23. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling**

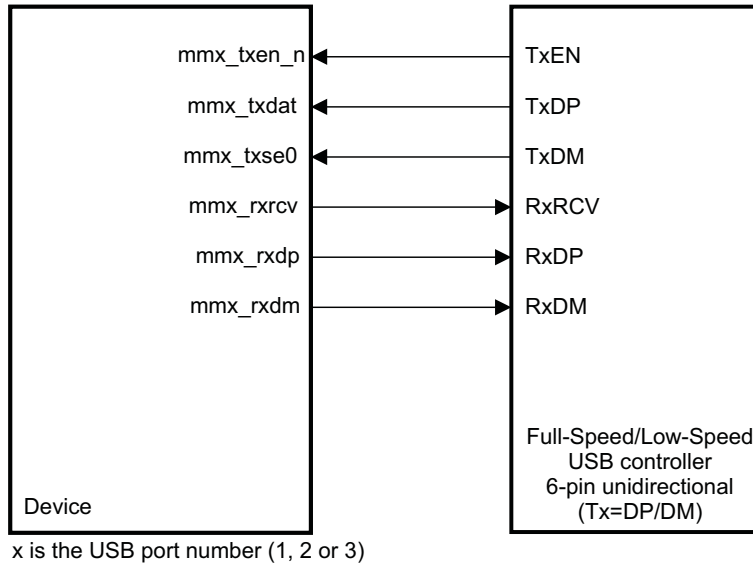

x is the USB port number (1, 2 or 3)

usb-022

Figure 24-24 shows an external device using DP/DM encoding.

**Figure 24-24. 6-Pin Unidirectional TLL Using DP/DM Signaling**

**24.2.2.4.4.2 Bidirectional TLL Modes**

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 24-25 shows an external device using DAT/SE0 encoding.

**Figure 24-25. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling**

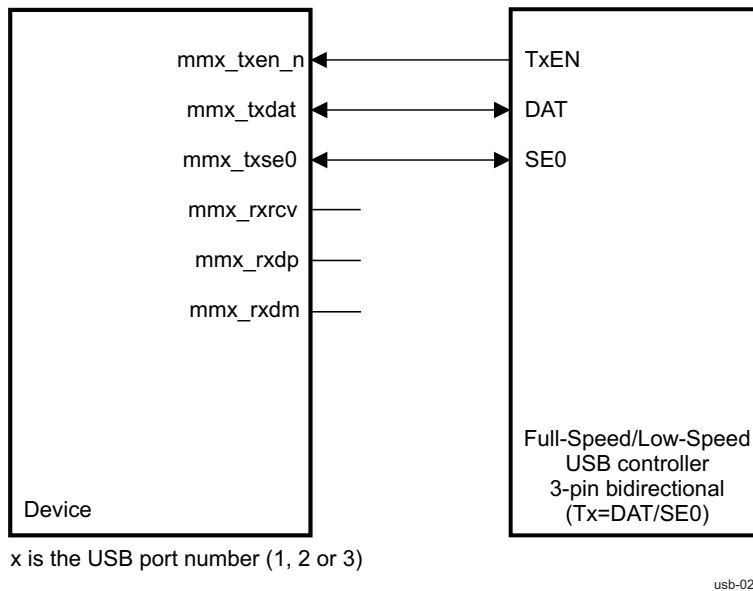

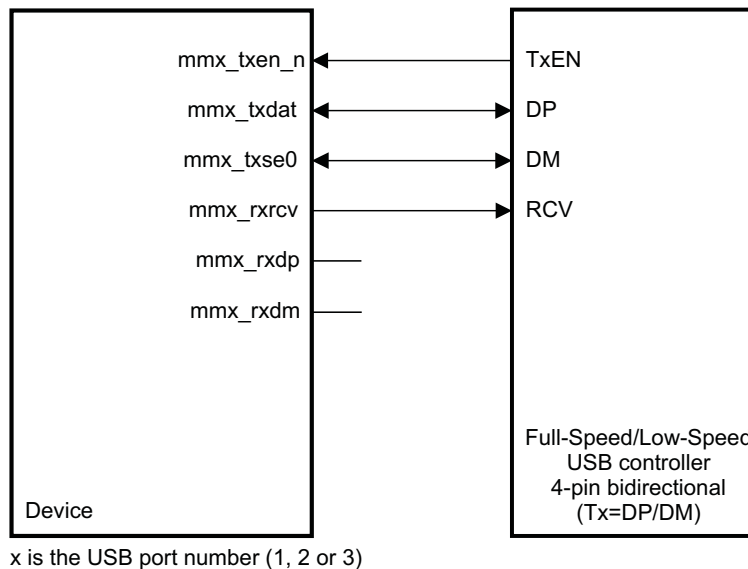

Figure 24-26 shows an external device using DP/DM encoding.

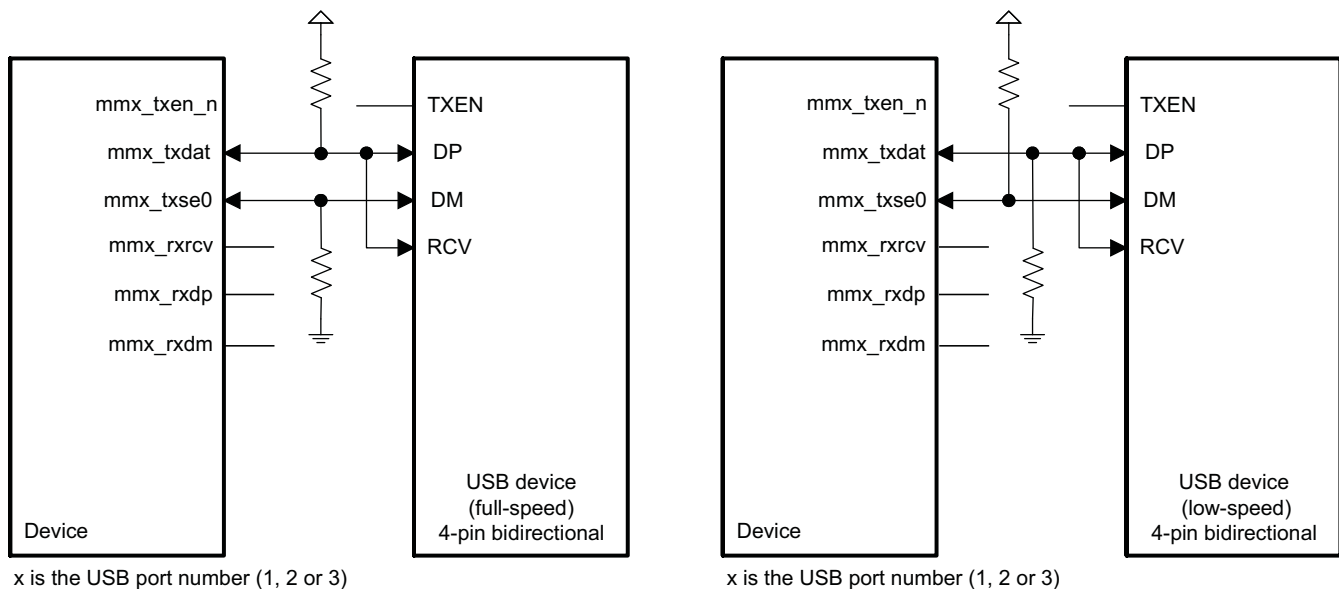

**Figure 24-26. 4-Pin Bidirectional TLL Using DP/DM Signaling**

usb-025

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 24-27 shows USB port using DP/DM encoding.

**Figure 24-27. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device**

2-pin bidirectional TLL using DP/DM encoding,  
against full-speed USB device

2-pin bidirectional TLL using DP/DM encoding,  
against low-speed USB device

usb-026

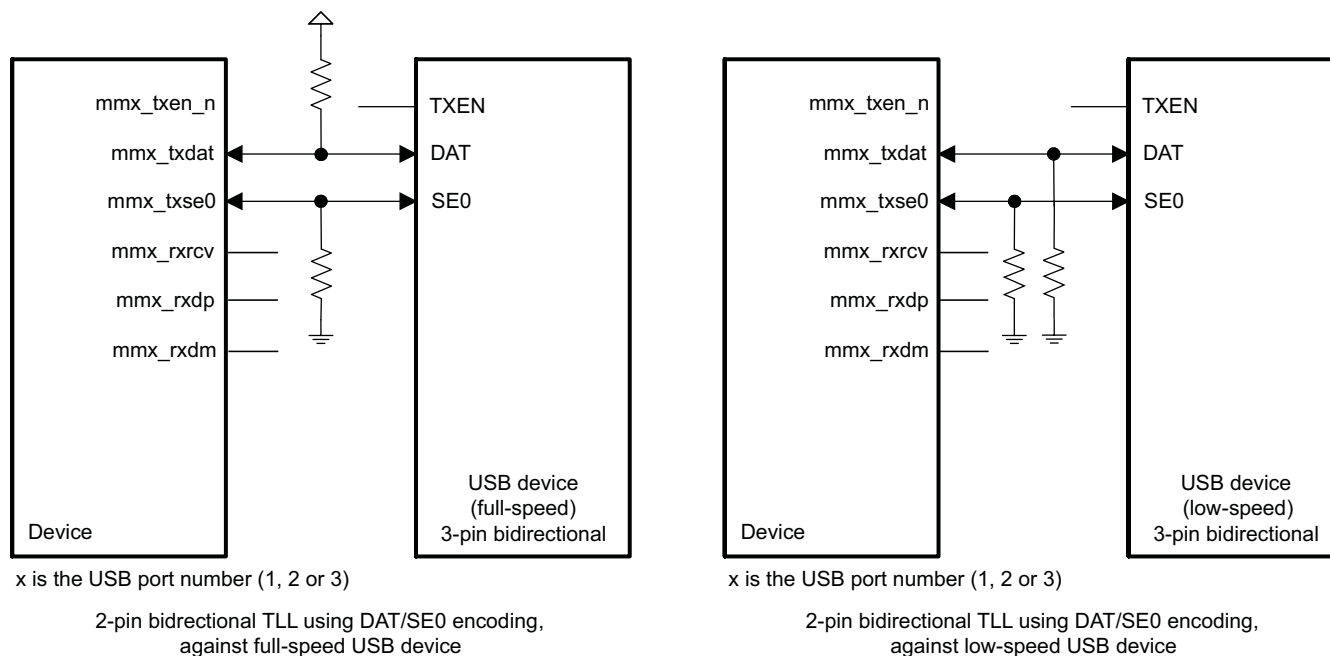

Table 24-27 shows the pullup/pulldown configuration for DP/DM encoding.

**Table 24-27. Pullup/Pulldown Configuration for DP/DM Encoding**

	Nonconnected Device (Any Speed)	Connected Low-Speed Device	Connected Full-Speed Device
DP	Pulldown	Pulldown	Pullup
DM	Pulldown	Pullup	Pulldown

Figure 24-28 shows a USB port using DAT/SE0 encoding.

**Figure 24-28. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device**

usb-027

Table 24-28 shows pullup/pulldown configuration for DAT/SE0 encoding.

**Table 24-28. Pullup/Pulldown Configuration for DAT/SE0 Encoding**

	Nonconnected Device (Any Speed)	Connected Low-Speed Device	Connected Full-Speed Device
DAT	Pulldown	Pulldown	Pullup
SE0	Pullup	Pulldown	Pulldown

**24.2.2.4.5 High-Speed USB Host Subsystem Interface Description**

Table 24-29 describes the I/O of the high-speed USB host subsystem serial interfaces.

**Table 24-29. I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Value at Reset
<b>Multiple-Mode FS/LS Serial Interface: Port 1</b>			
mm1_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode	
	I/O	SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode	

(1) I = Input, O = Output

### 24.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

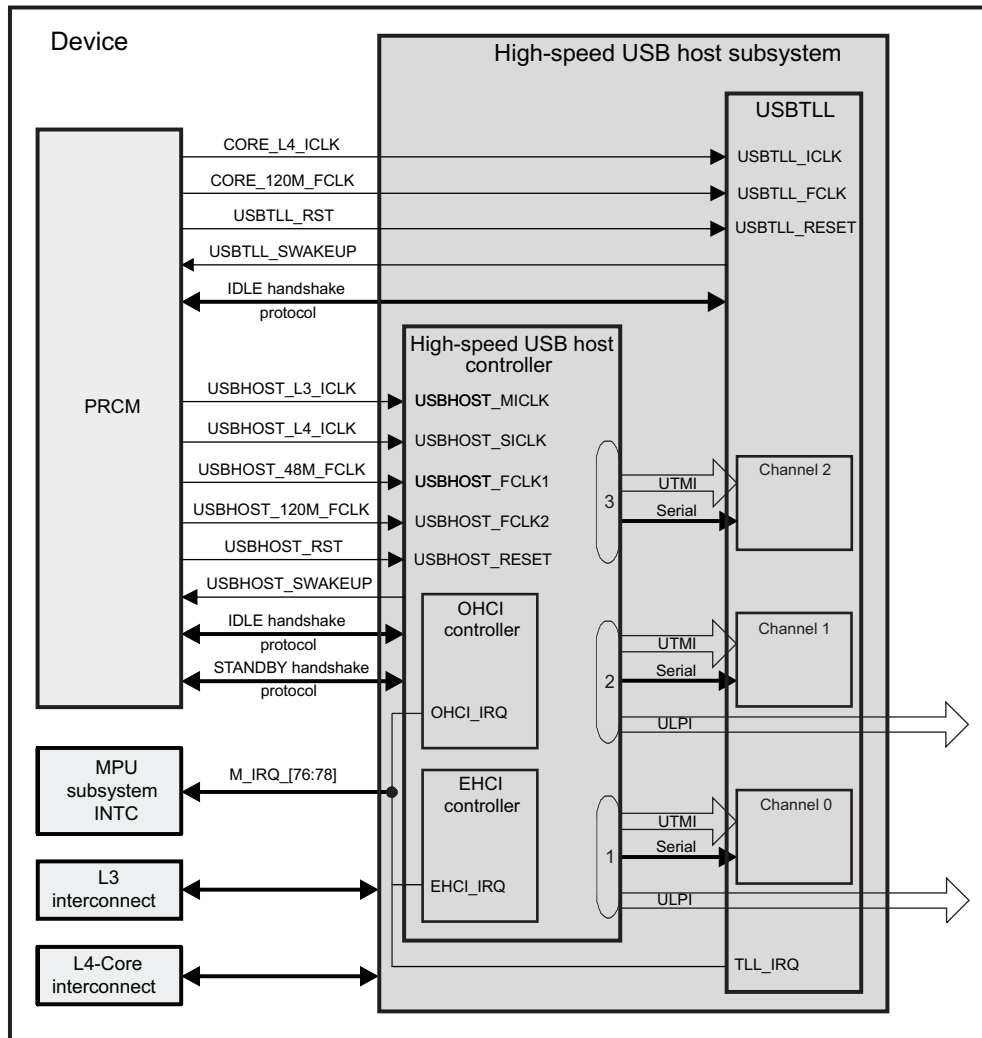

The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M\_IRQ\_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

[Figure 24-29](#) highlights the high-speed USB host subsystem integration in the device.

Figure 24-29. High-Speed USB Subsystem Integration

usb-028

### 24.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST\_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL\_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

#### 24.2.3.1.1 High-Speed USB Host Subsystem Resets

Table 24-30 lists and describes all the high-speed USB host subsystem resets:

**Table 24-30. High-Speed USB Host Subsystem Reset Description**

Type	Name	Source	Polarity	Description
Software	USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit	High-speed USB host controller internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Software	USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit	USBTLL module internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Hardware	USBHOST_RESET	PRCM USBHOST_RST signal	Active low	The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see <a href="#">Chapter 4, Power, Reset, and Clock Management</a> ).
Hardware	USBTLL_RESET	PRCM USBTLL_RST signal	Active low	The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see <a href="#">Chapter 4, Power, Reset, and Clock Management</a> ).

#### 24.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: The USBHOST\_RST signal resets the module. The USBTLL module is attached to the CORE power domain: The USBTLL\_RST signal resets asynchronously the module (see [Chapter 4, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the modules.

#### 24.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.UHH\_SYSCONFIG[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the high-speed USB host controller, and through the USBHOST.USBTLL\_SYSCONFIG[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

#### 24.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST\_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI and EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST\_48M\_FCLK output clock. USBHOST\_FCLK1 is controlled by the PRCM.PRCM.CM\_FCLKEN\_USBHOST[0] EN\_USBHOST1 bit (0: Disabled; 1: Enabled).
- USBHOST\_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST\_120M\_FCLK output clock. USBHOST\_FCLK2 is controlled by the PRCM.PRCM.CM\_FCLKEN\_USBHOST[1] EN\_USBHOST2 bit (0: Disabled; 1: Enabled).
- USBHOST\_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the

interconnect are synchronous to USBHOST\_MICLK. Its source is the PRCM USBHOST\_L3\_ICLK output clock. USBHOST\_MICLK is controlled by the PRCM.CM\_ICLKEN\_USBHOST[0] EN\_USBHOST bit (0: Disabled; 1: Enabled) and the PRCM.CM\_AUTOIDLE\_USBHOST[0] AUTO\_USBHOST bit (enables/disables automatic control of the interface clock).

- USBHOST\_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST\_SICLK. Its source is the PRCM USBHOST\_L4\_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL\_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE\_120M\_FCLK output clock. USBTLL\_FCLK is controlled by the PRCM.CM\_FCLKEN3\_CORE[2] EN\_USBTLL bit (0: Disabled; 1: Enabled).
- USBTLL\_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL\_ICLK. Its source is the PRCM CORE\_L4\_ICLK output clock. USBTLL\_ICLK is controlled by the PRCM.CM\_ICLKEN3\_CORE[2] EN\_USBTLL bit (0: Disabled; 1: Enabled) and the PRCM.CM\_AUTOIDLE3\_CORE[2] AUTO\_USBTLL bit (enables/disables automatic control of the interface clock).

Table 24-31 summarizes the high-speed USB host subsystem clocks.

**Table 24-31. High-Speed USB Host Subsystem Clocks**

Attributes	Frequency	Name	Module	Mapping	Comments
Functional clock	48 MHz	USBHOST_FCLK1	High-speed USB Host controller	USBHOST_48M_FCLK	Source is PRCM module
Functional clock	120 MHz	USBHOST_FCLK2	High-speed USB Host controller	USBHOST_120M_FCLK	Source is PRCM module
L3 master interface clock	Depending on PRCM register settings	USBHOST_MICLK	High-speed USB Host controller	USBHOST_L3_ICLK	Source is PRCM module
L4 slave interface clock	Depending on PRCM register settings	USBHOST_SICLK	High-speed USB Host controller	USBHOST_L4_ICLK	Source is PRCM module
Functional clock	120 MHz	USBTLL_FCLK	USBTLL	CORE_120M_FCLK	Source is PRCM module
L4 interface clock	Depending on PRCM register settings	USBTLL_ICLK	USBTLL	CORE_L4_ICLK	Source is PRCM module

#### 24.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST\_L3\_ICLK) is used only by the high-speed USB host controller (USBHOST\_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM\_ICLKEN\_USBHOST[0]:

0: Disabled  
1: Enabled

and PRCM.CM\_AUTOIDLE\_USBHOST[0] (enables/disables automatic control of the interface clock)—see Table 24-32.

**Table 24-32. High-Speed USB Controller L3 Master Interface Clock**

PRCM.CM_AUTOIDLE_USBHOST[0]	PRCM.CM_ICLKEN_USBHOST[0]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

**CAUTION**

The L3 master interface clock should not be below 30 MHz, ULPI clock divided by 2 (this can occur during DPLL3 relocking).

**24.2.3.1.2.2 L4 Slave Interface Clock**

The L4 slave interface clock (USBHOST\_L4\_ICLK) is used only by the high-speed USB host controller (USBHOST\_SICLK) in the subsystem, and comes from the PRCM module.

**24.2.3.1.2.3 L4 Interface Clock**

The L4 interface clock (CORE\_L4\_ICLK) is used only by the USBTLL module (USBTLL\_ICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM\_ICLKEN3\_CORE[2]:

- 0: Disabled
- 1: Enabled

and PRCM.CM\_AUTOIDLE3\_CORE[2] (enables/disables automatic control of the interface clock)—see [Table 24-33](#).

**Table 24-33. USBTLL Module Interface Clock**

PRCM.CM_AUTOIDLE3_CORE[2]	PRCM.CM_ICLKEN3_CORE[2]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

**24.2.3.1.2.4 Functional Clocks**

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST\_FLCK1 running at 48 MHz (USBHOST\_48M\_FCLK) and USBHOST\_FLCK2 running at 120 MHz (USBHOST\_120M\_FCLK).

The USBHOST\_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM\_FCLKEN\_USBHOST[0]:

- 0: Disabled
- 1: Enabled

The USBHOST\_FLCK2 functional clock is controlled by the PRCM register bit PRCM.CM\_FCLKEN\_USBHOST[1]:

- 0: Disabled
- 1: Enabled

The CORE\_120M\_FCLK functional clock is used only by the USBTLL module (USBTLL\_FCLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bit PRCM.CM\_FCLKEN3\_CORE[2]:

0: Disabled  
1: Enabled

### 24.2.3.1.3 Power-Management Scheme

#### 24.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

##### 24.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

[Table 24-34](#) details the high-speed USB host controller module PRCM clock control bits.

**Table 24-34. High-Speed USB Host Controller PRCM Clock Control Bits**

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBHOST_FCLK1	USBHOST_48M_FCLK	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit	N/A
USBHOST_FCLK2	USBHOST_120M_FCLK	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit	N/A
USBHOST_MICLK	USBHOST_L3_ICLK	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit	PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit

**Notes:**

- The PRCM USBHOST\_48M\_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST\_120M\_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST\_L3\_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM\_AUTOIDLE\_USBHOST[0] AUTO\_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST\_L3\_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 4, Power, Reset, and Clock Management](#).

### 24.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see [Figure 24-29](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH\_SYSCONFIG[13:12] MIDDLEMODE field.

**Table 24-35. High-Speed USB Host Controller MIDDLEMODE Settings**

MIDDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally).
0x1	No-standby	The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted).
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

### 24.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see [Chapter 4, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH\_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 24-36](#) details SIDLEMODE settings and the related acknowledgment modes.

**Table 24-36. High-Speed USB Host Controller SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The USBHOST.UHH\_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the interface clock internal gating while module is idle. [Table 24-37](#) details the CLOCKACTIVITY settings.

**Table 24-37. High-Speed USB Host Controller CLOCKACTIVITY Settings**

CLOCKACTIVITY Value	Interface Clock Effect	Description
0	OFF	Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request.
1	ON	Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

**CAUTION**

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the high-speed USB host controller CLOCKACTIVITY and PRCM interface clock control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM\_ICLKEN\_USBHOST register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

#### 24.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the USBTLL module clocks are no longer required, the USBTLL module can be deactivated at PRCM level in the corresponding registers.

[Table 24-38](#) details the USBTLL module PRCM clock control bits.

**Table 24-38. USBTLL Module PRCM Clock Control Bits**

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBTLL_FCLK	CORE_120M_FCLK	PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit	N/A
USBTLL_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit	PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTLL bit

**Notes:**

- The PRCM CORE\_120M\_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE\_L4\_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM\_AUTOIDLE3\_CORE[2] AUTO\_USBTLL bit is used to link/unlink the USBTLL module from CORE\_L4\_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 4, Power, Reset, and Clock Management](#).

At PRCM level, when all the conditions to shut off the USBTLL\_FCLK or USBTLL\_ICLK output clocks are met (see [Chapter 4, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL\_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 24-39](#) details SIDLEMODE settings and the related acknowledgment modes.

**Table 24-39. USBTLL Module SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL\_ICLK gating. The USBHOST.[USBTLL\\_SYSCONFIG](#)[9:8] CLOCKACTIVITY bit is used to control the USBTLL\_ICLK clock internal gating while the module is idle. [Table 24-40](#) details the CLOCKACTIVITY settings.

**Table 24-40. USBTLL Module CLOCKACTIVITY Settings**

CLOCKACTIVITY Value	USBTLL_ICLK Effect	Description
0	OFF	USBTLL_ICLK is considered for generating the acknowledgment. This setting also means USBTLL_ICLK is shut down upon PRCM IDLE request.
1	ON	USBTLL_ICLK is not shut down upon PRCM IDLE request. The USBTLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

**CAUTION**

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL\_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM\_ICLKEN3\_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

**24.2.3.2 Hardware Requests****24.2.3.2.1 Interrupt Requests**

[Table 24-41](#) lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

**Table 24-41. High-Speed USB Host Subsystem Interrupts**

Name	Mapping	Comments
<b>HS USB OHCI Host Controller Interrupt</b>		
OHCI_IRQ	M_IRQ_76	Destination is MPU subsystem interrupt controller
<b>HS USB EHCI Host Controller Interrupt</b>		
EHCI_IRQ	M_IRQ_77	Destination is MPU subsystem interrupt controller
<b>USBTLL Module Interrupt</b>		
TLL_IRQ	M_IRQ_78	Destination is MPU subsystem interrupt controller

**24.2.3.2.2 IDLE Handshake Protocol**

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

**24.2.3.2.3 MSTANDBY Handshake Protocol**

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

**24.2.3.2.4 Wake-Up Request**

Wake-up request signal USBHOST\_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL\_SWAKEUP is generated by the USBTLL module to the PRCM module.

## 24.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

### 24.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following public specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

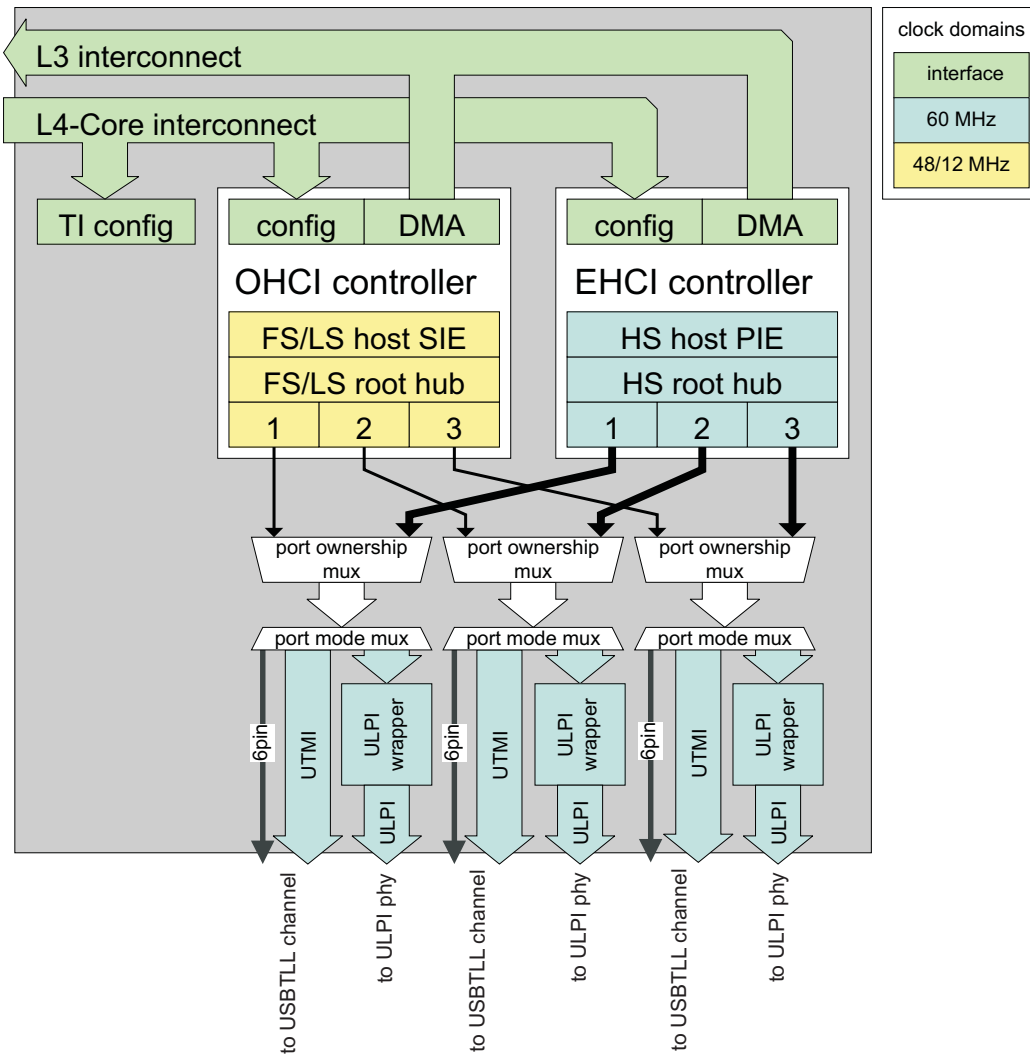

#### 24.2.4.1.1 High-Speed USB Host Controller Architecture

[Figure 24-30](#) shows an overview of the high-speed USB host controller internal architecture: It contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.
- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 24-30. High-Speed USB Host Controller Architecture

usb-029

#### 24.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see Section 24.2.6.4.3, *OHCI Registers*). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- USBHOST.HCFMINTERVAL[30:16] FSMPS field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.
- USBHOST.HCRHDESCRIPTORA[7:0] NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- USBHOST.HCRHDESCRIPTORA[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- USBHOST.HCRHDESCRIPTORA[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally (default must be = OCPM).
- USBHOST.HCRHDESCRIPTORA[31:24] POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power rampup time is 10 x 2 ms = 20 ms.
- USBHOST.HCRHDESCRIPTORB[15:0] DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.

- USBHOST.HCRHDESCRIPTORB[31:16] PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

#### 24.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS, USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS, and USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bits).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don’t care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

#### 24.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS, USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS, and USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bits).

In ULPI mode, all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don’t care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHz) clock to the transceiver on the ULPI interface. This is called ULPI “input” clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, “output mode” (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

#### 24.2.4.1.5 Port Status

The USB port status is given through the USBHOST.UHH\_HOSTCONFIG[10:8] bit field. The default value of the following bits is 1:

- USBHOST.UHH\_HOSTCONFIG[8] P1\_CONNECT\_STATUS
- USBHOST.UHH\_HOSTCONFIG[9] P2\_CONNECT\_STATUS
- USBHOST.UHH\_HOSTCONFIG[10] P3\_CONNECT\_STATUS

### **CAUTION**

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, `USBHOST.HCRHPORTSTATUS_1` for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the `USBHOST.UHH_HOSTCONFIG` bits to indicate the correct port connect status.

#### **24.2.4.1.6 Save and Restore**

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the “buried” flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The `PRCM.PM_PWSTCTRL_USBHOSTE[4]` `SAVEANDRESTORE` bit enables the SAR mechanism for the high-speed USB host controller (see [Chapter 4, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

#### **24.2.4.1.7 Burst Control**

To avoid buffer underflow bursts shall be enabled by writing 0x7 in `USBHOST.UHH_HOSTCONFIG[4:2]` and 0x0 in `USBHOST.UHH_HOSTCONFIG[5]` `ENA_INCR_ALIGN`.

### **24.2.4.2 USBTLL Module Functionality**

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software “handles” should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

#### **24.2.4.2.1 Channels and Ports**

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An “input” goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an “output” goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. Table 24-42 summarizes the ports features.

**24.2.4.2.2 Channel Architecture**

Figure 24-31 shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI\* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

**Figure 24-31. USBTLL Channel**

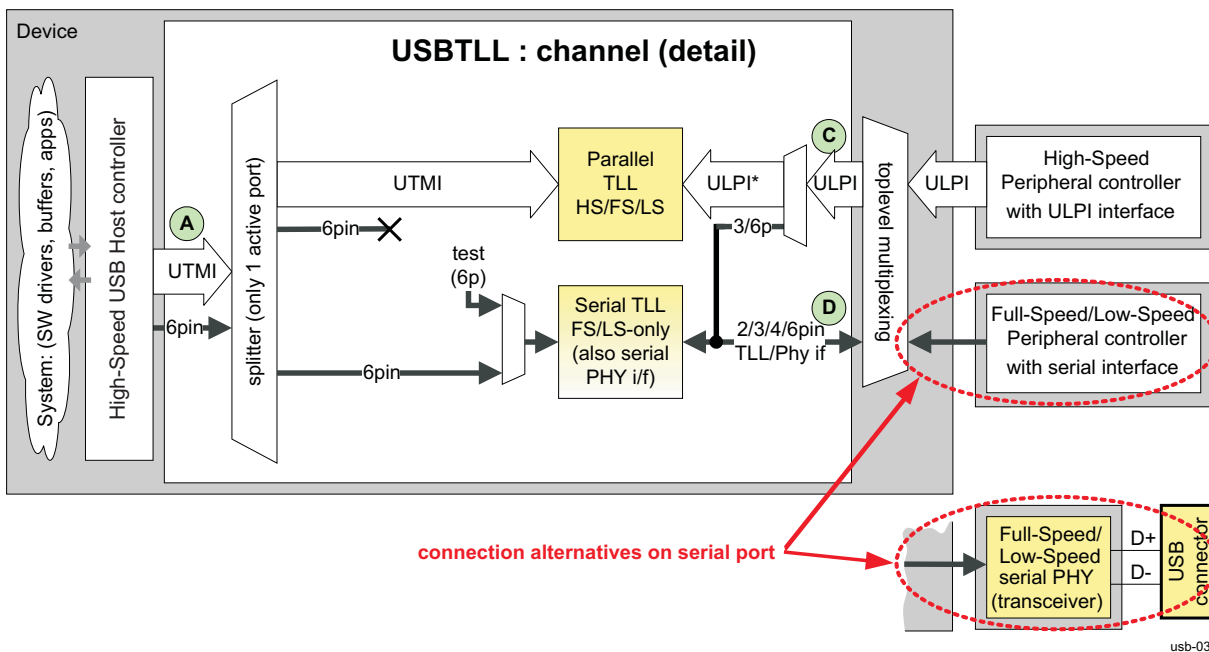

Table 24-42 summarizes the properties of each port.

**Table 24-42. USBTLL Channel USB Ports**

USBTLL Port	Port Description	Connect to Controller	Connect to Transceiver	Serial (Full-Speed/ Low-Speed only)	Parallel (High-Speed/ Full-Speed/Low-Speed)
A	PHY-side UTMI+	UTMI+ (L3)	No	6-pin	60-MHz UTMI
C	PHY-side ULPI	ULPI TLL	No	6-pin	60-MHz UTMI
D	Multimode Serial	6-/4-/3-/2-pin TLL	6-/4-/3-/2-pin	6-/4-/3-/2-pin TLL	No

#### 24.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI “local” port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHz UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS “6-pin” mode

#### 24.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes
- Supports optional input clocking mode

#### 24.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

#### 24.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 24-43](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

[Table 24-43](#) describes the available modes and the software settings required for each. Channel *i* has the following settings:

- CHANMODE: USBHOST.TLL\_CHANNEL\_CONF\_i[2:1] CHANMODE field
- FLSMODE: USBHOST.TLL\_CHANNEL\_CONF\_i[27:24] FLSMODE field
- FLSSESERIALMODE\_3PIN/6PIN: Either the ULPI PHY-side USBHOST.ULPI\_INTERFACE\_CTRL[1] FLSSESERIALMODE\_3PIN bit or the USBHOST.ULPI\_INTERFACE\_CTRL[0] FLSSESERIALMODE\_6PIN bit (only one can be set to 1 at a time)

**Table 24-43. USBTLL Channel Configuration**

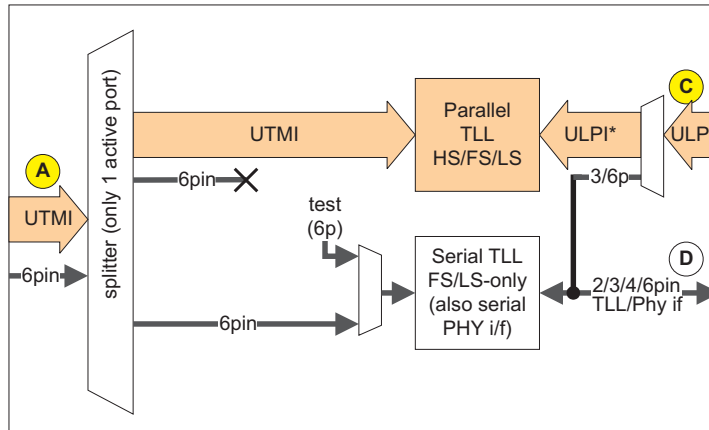

Configuratio n	Mode	CHAN MODE	FLSMODE	Other Settings	Ports	Speed	Remote Port Connection
2	ULPI synchronous TLL	0	N/A	FLSSESERIALMODE_ 3PIN/6PIN = 0	A–C	HFL	ULPI link (peripheral controller)
4	Serial UTMI to serial ULPI TLL	0	N/A	FLSSESERIALMODE_ 3PIN/6PIN = 1	A–C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
6	Serial UTMI to serial TLL	1	0x4 to 0x7; 0xA to 0xB	-	A–D	FL	Serial link (2-/3-/4-/6-pin)

**Table 24-43. USBTLL Channel Configuration (continued)**

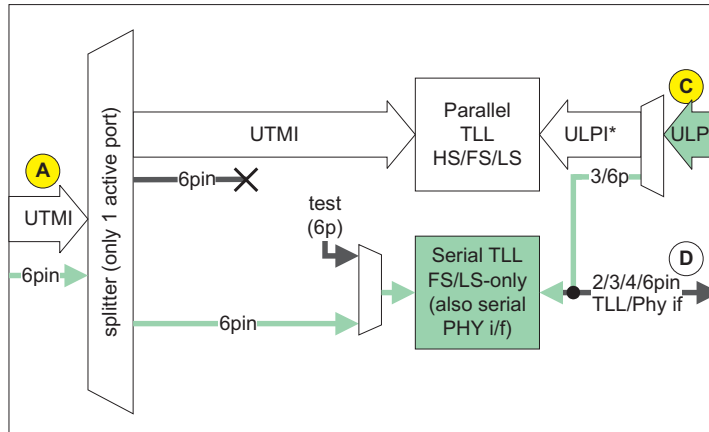

Configuration	Mode	CHAN MODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
6	Serial UTMI to serial PHY	1	0x0 to 0x3	-	A-D	FL	Serial transceiver (2-/3-/4-/6-pin)

**Figure 24-32. Per-Configuration Datapath Through USBTLL**

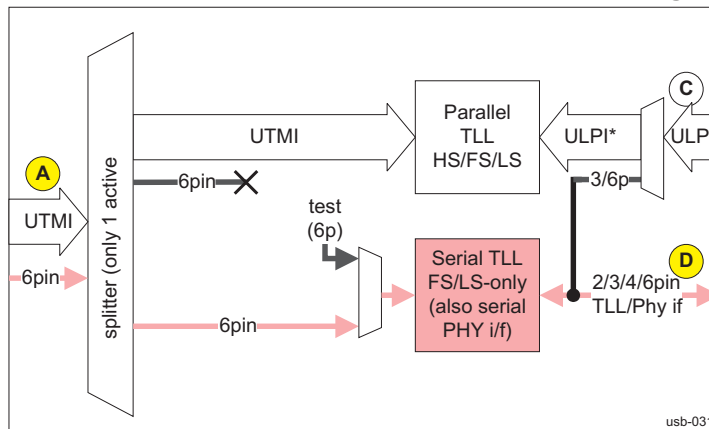

**2: Sync UTMI to sync ULPI TLL config (HS/FS/LS)**

**4: Serial UTMI to serial ULPI TLL config (FS/LS)**

**6: Serial UTMI to serial ULPI, TLL or PHY config**

#### 24.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 24-17](#) and [Figure 24-18](#) and the related explanations.

##### 24.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

##### 24.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also [Figure 24-17](#).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup “charge”, VBUS pulldown “discharge”) is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the `USBHOST.TLL_CHANNEL_CONF_i` `DRVVBUS` and `CHRGVBUS` bits, as indicated in [Table 24-44](#).

[Table 24-44](#) lists the values to write to the `USBHOST.TLL_CHANNEL_CONF_i` register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields' actual signification is:

- `DRVVBUS`: Set to 1 to report a VBUS level greater than *VBUS valid*.
- `CHRGVBUS`: Set to 1 to report a VBUS level greater than *Session valid*

**Table 24-44. VBUS Level Software Reporting for Serial Transceiver Configuration**

VBUS Status	USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit	USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

##### 24.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.

- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a “don’t care”

#### 24.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

Table 24-45 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

**Table 24-45. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode**

VBUS Controls (Actions)			VBUS Level	VBUS Status		
USBHOST.ULPI_OTG_CTRL[5] DRVVBUS Bit	USBHOST.ULPI_OTG_CTRL[4] CHRGVBUS Bit	USBHOST.ULPI_OTG_CTRL[3] DISCHRGVBUS Bit		USBHOST.ULPI_USB_INT_STATUS[1] VBUSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[2] SESSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[3] SESSEND Bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

#### 24.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See Figure 24-18.

VBUS control can be done in software, by writing to the following fields of the USBHOST.TLL\_CHANNEL\_CONF\_i register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

#### 24.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the USBHOST.TLL\_CHANNEL\_CONF\_i[27:24] FLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

Table 24-46 shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

**Table 24-46. Serial Mode Description, Signal Functionality**

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DAT/SE0	DP/DM
Pin usage	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 <sup>(1)</sup>	6 or 5 <sup>(1)</sup>	3	4 or 3 <sup>(2)</sup>	2	2
<b>I/O Pad Function Per Mode</b>										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDM	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDM	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

<sup>(1)</sup> RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

<sup>(2)</sup> Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

#### 24.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL\_CHANNEL\_CONF\_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL\_CHANNEL\_CONF\_i[27:24] FLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL\_CHANNEL\_CONF\_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL\_CHANNEL\_CONF\_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
  - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
  - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL\_CHANNEL\_CONF\_i[5] TLLCONNECT bit emulates the USB electrical connect (that is,

the pullup by the USB peripheral of one of the two USB lines [by a 1.5KOhm resistor]), which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal — the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.

- USBHOST.TLL\_CHANNEL\_CONF\_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): See [Table 24-47](#).
- The 15kOhm pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

---

**Note:** Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require any custom additions.

---

**Table 24-47. Pullup Enable Emulation in Serial TLL Modes**

USBHOST.TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	on	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

#### 24.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM\_PWSTCTRL\_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see [Chapter 4, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

[Table 24-48](#) lists the USBTLL registers impacted by the SAR context.

---

**Note:** Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

---

**Table 24-48. USBTLL Registers Impacted by the SAR Context**

## 24.2.5 High-Speed USB Host Subsystem Basic Programming Model

### 24.2.5.1 Selecting and Configuring USB Connectivity

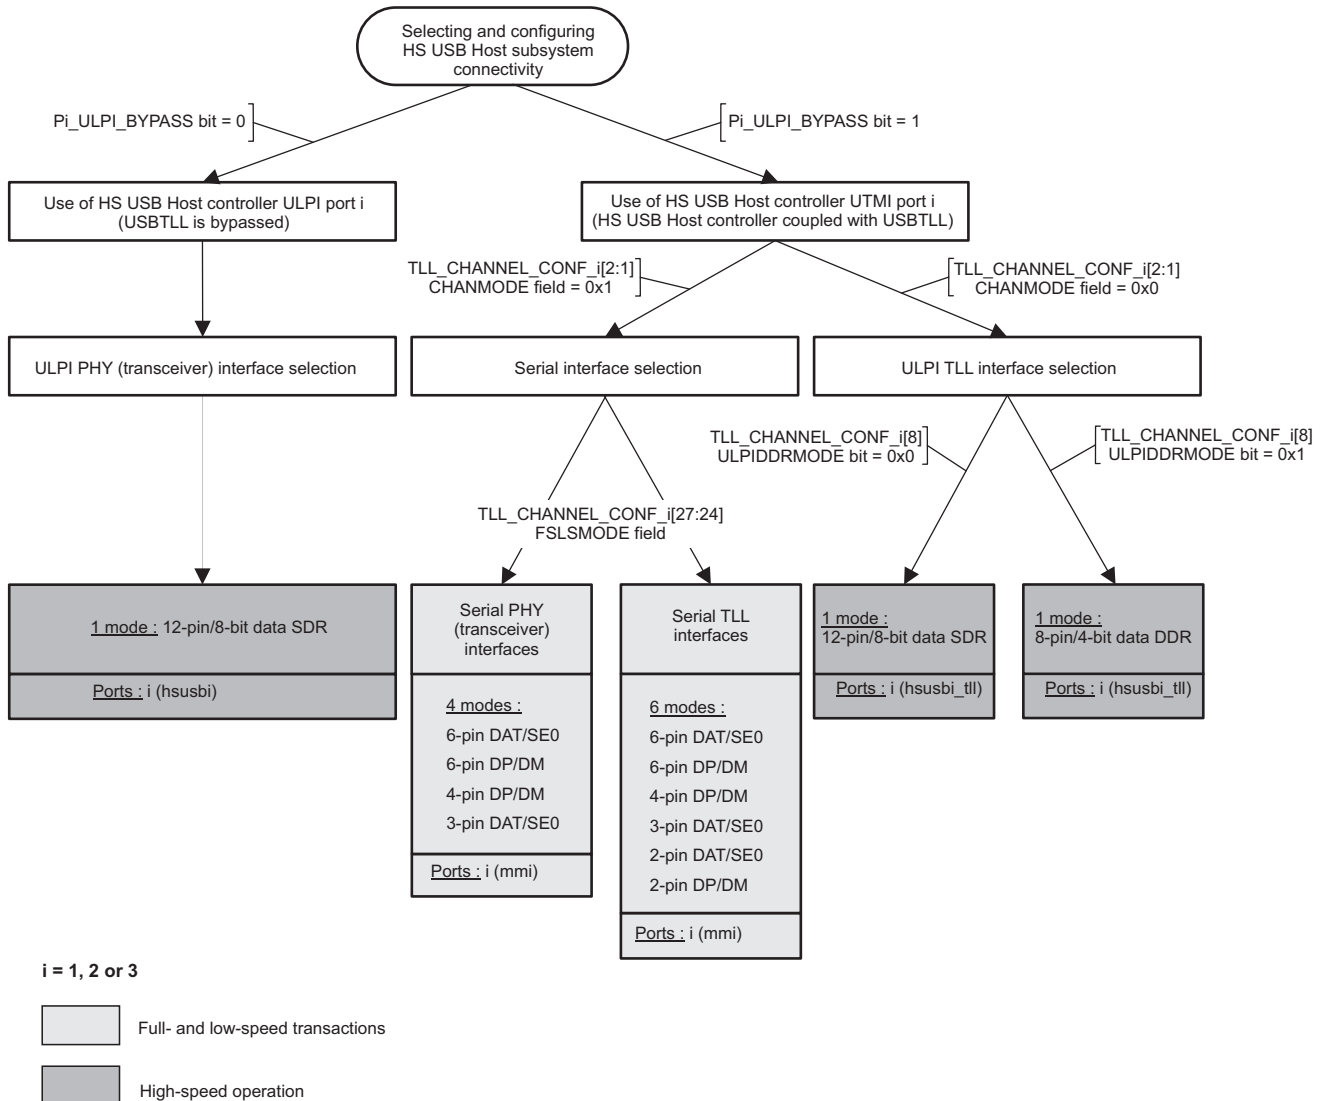

Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

Figure 24-33 shows how to select and configure the high-speed USB host subsystem connectivity.

**Figure 24-33. Selecting and Configuring High-Speed USB Host Subsystem Connectivity**

usb-034

**Notes:**

- When the USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS bit is 0 (the port 3 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 3.
- When the USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS bit is 0, (the port 2 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 2.
- When the USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bit is 0 (the port 1 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 1.
- When the USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS bit is 1, (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 3 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS bit is 1 (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 2 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and port 1 can be configured in any ULPI TLL or serial mode.

#### 24.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
  - ULPI interfaces: 12-pin/8-bit data version
- TLL
  - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

##### 24.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used). The USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS, USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS, or USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bit must be cleared to 0, depending on the port used in ULPI mode.

##### 24.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The USBHOST.UHH\_HOSTCONFIG[12] P3\_ULPI\_BYPASS, USBHOST.UHH\_HOSTCONFIG[11] P2\_ULPI\_BYPASS, or USBHOST.UHH\_HOSTCONFIG[0] P1\_ULPI\_BYPASS bit must be set to 1, depending on the port used in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see [Section 24.2.4.2.3, Channel Configurations](#)).

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL\_CHANNEL\_CONF\_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the `USBHOST.TLL_CHANNEL_CONF_i[8]` `ULPIDDRMODE` bit (0: SDR mode; 1: DDR mode).

### 24.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
  - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The `USBHOST.UHH_HOSTCONFIG[12]` `P3_ULPI_BYPASS`, `USBHOST.UHH_HOSTCONFIG[11]` `P2_ULPI_BYPASS`, or `USBHOST.UHH_HOSTCONFIG[0]` `P1_ULPI_BYPASS` bit must be set to 1, depending on the port. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see [Section 24.2.4.2.3, Channel Configurations](#)).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the `USBHOST.TLL_CHANNEL_CONF_i[27:24]` `FSLSMODE` field only when the main channel mode is serial (`USBHOST.TLL_CHANNEL_CONF_i[2:1]` `CHANMODE` field = 0x1 = UTMI-to-serial mode).

**Table 24-49. USB Connectivity Mode Description**

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL Mode (Alt)	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
<code>USBHOST.TLL_CHANNEL_CONF_i[27:24]</code> <code>FSLSMODE</code> field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DAT/SE0	DP/DM
Pin usage	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 <sup>(1)</sup>	6 or 5 <sup>(1)</sup>	3	4 or 3 <sup>(2)</sup>	2	2

<sup>(1)</sup> RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused

<sup>(2)</sup> Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

### 24.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

#### **24.2.5.2.1 TLL Control and Status Registers**

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. These registers are:

- Standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

#### **24.2.5.2.2 ULPI PHY-side Registers**

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. Upon resume, the ULPI register contents have been lost and can be restored over L4-Core interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

## 24.2.6 High-Speed USB Host Subsystem Register Manual

### 24.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: Immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x40- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x100- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED\_SET\_ACCESS in [Table 24-50](#)). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively `_SET` and `_CLR`. The register fields are described only once, at the write address (see [Section 24.2.6.4, EHCI Registers](#)).

---

**Note:** Some ULPI registers are cleared upon read.

---

#### 24.2.6.2 L4-Core Interconnect Register Space

Table 24-51 lists the base address and address space for the high-speed USB host subsystem.

**Table 24-51. High-Speed USB Host Subsystem Instance Summary**

Module Name	Base Address (hex)	Size
USBTLL	0x4806 2000	4096 bytes
UHH_config	0x4806 4000	1024 bytes
OHCI	0x4806 4400	1024 bytes
EHCI	0x4806 4800	1024 bytes

#### 24.2.6.3 High-Speed USB Host Subsystem Register Mapping Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

Table 24-52 lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

**CAUTION****On ULPI PHY-side register access over L4-Core interconnect:**

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: Oversized read accesses to adjacent memory locations could cause unwanted clears.

**Table 24-52. USBTLL Registers Mapping Summary (L4-Core Interconnect Register Space)**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

## High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved	R	0x0
29:28	FSLSLINESTATE	Line state for Full/Low speed serial modes Bit1 = D- / Bit0 = D+ 0x0: Single-ended 0 0x1: Full-Speed J = differential 1 0x2: Full-Speed K = differential 0 0x3: Single-ended 1 (illegal in USB)	R	0x0
27:24	FSLSMODE	Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: "6pin" unidirectional PHY i/f mode. TX encoding is Dat/Se0 (default) 0x1: "6-pin" unidirectional PHY i/f mode. TX encoding is Dp/Dm 0x2: "3-pin" bidirectional PHY i/f mode. 0x3: "4-pin" bidirectional PHY i/f mode. 0x4: "6pin" unidirectional TLL mode. TX encoding is Dat/Se0 0x5: "6pin" unidirectional TLL mode. TX encoding is Dp/Dm 0x6: "3-pin" bidirectional TLL mode. 0x7: "4-pin" bidirectional TLL mode. 0xA: "2-pin" bidirectional TLL mode. Encoding is Dat/Se0 0xB: "2-pin" bidirectional TLL mode. Encoding is Dp/Dm	RW	0x0
23:21	RESERVED	Reserved	R	0x0
20	TESTTXSE0	Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) 0x0: Drive differential value on TX according to TestTXDat 0x1: Drive SE0 on TX	RW	0x0
19	TESTTXDAT	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) or TestSe0 = 1 (tx = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1	RW	0x0
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: Pullups determine line state)	RW	0x0
17	TESTEN	Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled	RW	0x0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V	RW	0x0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0x0
14:12	RESERVED	Reserved	R	0x0

Bits	Field Name	Description	Type	Reset
11	ULPINOBITSTUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard)	RW	0x0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	0x1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	0x1
8	ULPIDDRMODE	Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit/12 pin) 0x1: DDR mode (4 data bit/8 pin)	RW	0x0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output	RW	0x1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: Input m(N)_tlpuen, register field TIConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	0x1
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected	RW	0x0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: Cable detach emulated on serial TLL 0x1: Cable attach emulated on serial TLL	RW	0x1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	0x1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): To ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: To serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: To UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unlocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0x0

<b>Description</b>	Standard system configuration register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																		MIDLEMODE		RESERVED		CLOCKACTIVITY		RESERVED		SIDLEMODE		ENAWAKEUP		SOFTRESET		AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Reserved	R	0x00000
13:12	MIDLEMODE	Master interface power management control. Standby/wait control 0x0: Force-standby mode. Mstandby asserted unconditionally 0x1: No-standby mode. Mstandby never asserted. 0x2: Smart-standby mode. Mstandby asserted when initiator activity stops	RW	0x0
11:9	RESERVED	Reserved	R	0x0
8	CLOCKACTIVITY	Control of clock internal gating while module is idle. One bit per clock, actual register width depends on the number of functional clocks controlled. Lower bit: Interface clock Upper bits (if any): Functional clocks 1: Clock is kept on during idle 0: Clock is switched off during idle	RW	0x0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management control. Idle Req/ack control 0x0: Force-Idle mode. Sidleack asserted after Idlreq assertion 0x1: No-idle mode. Sidleack never asserted. 0x2: Smart-idle mode. Sidleack asserted upon Idlreq assertion, after target activity is over	RW	0x0
2	ENAWAKEUP	Asynchronous wakeup generation control (Swakeup) 0x0: Wakeup generation disabled 0x1: Wakeup generation enabled	RW	0x0
1	SOFTRESET	Module software reset 0x0: No effect 0x1: Starts softreset sequence.	W	0x0
0	AUTOIDLE	Internal autogating control 0x0: Clock always running 0x1: When no activity on L3 interconnect, clock is cut off.	RW	0x1

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	R	0x00000000
12	P3_ULPI_BYPASS	Host controller (root hub) port 3 control. 0x0: ULPI port 3 is active (and UTMI port 3 is inactive) 0x1: UTMI port 3 is active (and ULPI port 3 is inactive)	RW	0
11	P2_ULPI_BYPASS	Host controller (root hub) port 2 control. 0x0: ULPI port 2 is active (and UTMI port 2 is inactive) 0x1: UTMI port 2 is active (and ULPI port 2 is inactive)	RW	0

## High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
10	P3_CONNECT_STATUS	Connection status for port 3. 0x0: USB port 3 is disconnected 0x1: USB port 3 is connected and in use (also the default state)	RW	0x1
9	P2_CONNECT_STATUS	Connection status for port 2. 0x0: USB port 2 is disconnected 0x1: USB port 2 is connected and in use (also the default state)	RW	0x1
8	P1_CONNECT_STATUS	Connection status for port 1. 0x0: USB port 1 is disconnected 0x1: USB port 1 is connected and in use (also the default state)	RW	0x1
7:6	RESERVED	Reserved	RW	0x0
5	ENA_INCR_ALIGN	Force alignment of bursts to the respective burst-size boundaries 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
4	ENA_INCR16	Control the use of INCR16-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
3	ENA_INCR8	Control the use of INCR8-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
2	ENA_INCR4	Control the use of INCR4-type bursts (in AHB sense) 0x0: Disable burst type 0x1: Enable burst type	RW	0x0
1	RESERVED	Reserved	RW	0x0
0	P1_ULPI_BYPASS	Host controller (root hub) port 1 control. 0x0: ULPI port 1 is active (and UTMI port 1 is inactive) 0x1: UTMI port 1 is active (and ULPI port 1 is inactive)	RW	0

<b>Address Offset</b>	0x0000 0044	<b>Instance</b>	UHH_config
<b>Physical Address</b>	0x4806 4044		
<b>Description</b>	Debug control and status for the EHCI, OHCI hosts.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								OHCI_CCS_3	OHCI_CCS_2	OHCI_CCS_1	OHCI_GLOBALSUSPEND	RESERVED								OCHI_CNTSEL	EHCI_SIMULATION_MODE	EHCI_FLADJ									

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19	OHCI_CCS_3	Current Connect Status of port 3 0x0: No periph connected 0x1: Periph connected	R	0x0
18	OHCI_CCS_2	Current Connect Status of port 2 0x0: No periph connected 0x1: Periph connected	R	0x0
17	OHCI_CCS_1	Current Connect Status of port 1 0x0: No periph connected 0x1: Periph connected	R	0x0
16	OHCI_GLOBALSUSPEND	OHCI global suspend status, asserted 5ms after the suspend order. 0x0: Host is not suspended 0x1: Host is suspended	R	0x0
15:8	RESERVED	Reserved	R	0x00
7	OCHI_CNTSEL	Selection of a shorter "1 ms" counter in OHCI host, to speed up long USB phases like reset, resume, etc (Used only for simulation.) 0x0: Functional mode, 1ms = 12,000 x 12 MHz cycles 0x1: Simulation mode, 1ms = 7 x 12 MHz cycles = 583 ns	RW	0x0
6	EHCI_SIMULATION_MODE	Sets the PHY to non-driving mode. (Used only for simulation.) 0x0: Functional mode 0x1: PHY set to non-driving	RW	0x0
5:0	EHCI_FLADJ	EHCI host frame length adjust. Modify only when EHCI bitfield <a href="#">USBSTS.HCHalted</a> = 1 Field value + 59,488 = 60,000 by default = number of 60 MHz UTMI/ULPI clock cycles per 1 ms USB frame = number of 480 MHz HS bits per 125 us HS USB microframe	RW	0x20

RESERVED																RWE	RWC	IR	HCFS	BLE	CLE	IE	PLE	CBSR							
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>																<b>Type</b>	<b>Reset</b>												
31:11	RESERVED	Reserved																R	0x000000												
10	RWE	Remote wake-up enable This bit is used to enable or disable the remote wakeup feature upon detection of upstream resume signaling.																RW	0												
9	RWC	Remote wake-up connected. This bit indicates whether the host controller supports remote wakeup signaling.																RW	0												
8	IR	Interrupt routing. This bit determines the routing of interrupts generated by events registered in USBHOST.HCINTERRUPTSTATUS. 0x0: All interrupts are routed to the normal host bus interrupt mechanism. 0x1: interrupts are routed to the system management Interrupt.																RW	0												
7:6	HCFS	Host Controller Functional State 0x0: HCFS: USB Reset 0x1: HCFS: USB Resume 0x2: HCFS: USB Operational 0x3: HCFS: USB Suspend																RW	0x0												
5	BLE	Bulk list processing enable. 0x0: Bulk ED list is not processed after the next SOF. 0x1: Enables processing of bulk ED list in the next frame.																RW	0												

Bits	Field Name	Description	Type	Reset
4	CLE	Control list processing enable. 0x0: Control ED list is not processed after the next SOF. 0x1: Enables processing of control ED list in the next frame.	RW	0
3	IE	Isochronous ED processing enabled by Host Controller Driver. 0x0: Isochronous EDs are not processed 0x1: Enables processing of isochronous EDs.	RW	0
2	PLE	Periodic list enable 0x0: Periodic ED lists are not processed after the next frame. 0x1: Enables processing of periodic ED lists in the next frame.	RW	0
1:0	CBSR	Control/bulk service ratio. Specifies the ratio between control and bulk EDs processed in a frame. 0x0: One control ED per bulk ED 0x1: Two control ED per bulk ED 0x2: Three control ED per bulk ED 0x3: Four control ED per bulk ED	RW	0x0

<b>Address Offset</b>	0x0000 0008	
<b>Physical Address</b>	0x4806 4408	<b>Instance</b> OHCI
<b>Description</b>	HC Command and Status	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SOC		RESERVED										OCR	BLF	CLF	HCR		

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R	0x0000
17:16	SOC	Scheduling overrun count. This is used to monitor any persistent scheduling problems. These bits are incremented on each scheduling overrun error. It is initialized to 0x0 and wraps around at 0x3.	R	0x0
15:4	RESERVED	Reserved	R	0x000
3	OCR	Ownership change request. This bit is set to request a change of control of the host controller.	RW	0
2	BLF	Bulk list filled. This bit is used to indicate whether there are any TDs on the bulk list. It is set whenever it adds a TD to an ED in the bulk list.	RW	0
1	CLF	Control list filled. This bit is used to indicate whether there are any TDs on the control list. It is set whenever it adds a TD to an ED in the control list.	RW	0
0	HCR	Host controller reset. (software reset) Set this bit to initiate a USB host controller reset. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this register returns a 0. 0x0: No effect 0x1: USB host controller is reset.	RW	0

18	PSSC	Port 3 suspend status change. This bit is set when the Port 3 port suspend status has changed. Write 0x0: No effect. Write 0x1: Clears this bit.	RW	0
17	PESC	Port 3 enable status change. This bit is set when the Port 3 port enable status has changed. Write 0x0: No effect. Write 0x1: Clears this bit.	RW	0
16	CSC	Port 3 connect status change. This bit is set when the Port 3 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect. Write 0x1: Clears this bit. Note: If the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 3 low-speed device attached/clear port power. This bit is valid only when port 3 current connect status is 1. Read 0x0: A full-speed device is attached to port 3. Read 0x1: A low-speed device is attached to port 3. Write 0x0: No effect. Write 0x1: Clears the port 3 port power status.	RW	0
8	PPS_SPP	Port 3 power status/set port power. Read 0x0: Port 3 power is enabled. Read 0x1: Port 3 power is not enabled. Write 0x0: No effect. Write 0x1: Sets the port 3 port power status bit.	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 3 reset status/set port reset. Read 0x0: USB reset is not being sent to port 3. Read 0x1: Port 3 is signaling the USB reset. Write 0x0: No effect. Write 0x1: Sets the port 3 port reset status bit and causes the USB host controller to begin signaling USB reset to port 3.	RW	0
3	RESERVED	Reserved	RW	0

Bits	Field Name	Description	Type	Reset
2	PSS_SPS	Port 3 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect. Read 0x0: Port 3 is not in the USB suspend state. Read 0x1: Port 3 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 3 current connect status is 1, sets the port 3 port suspend status bit and places port 3 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 3 enable status/set port enable. This bit is automatically set at completion of port 3 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 3 is not enabled. Read 0x1: Port 3 is enabled. Write 0x0: No effect. Write 0x1: When port 3 current connect status is 1 sets the port 3 port enable status bit. When port 3 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 3 current connection status/clear port enable. Read 0x0: No USB device is attached to port 3. Read 0x1: Port 3 currently has a USB device attached. Write 0x0: No effect. Write 0x1: Clears the port 3 port enable bit. Note: This bit is set to 1 if the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set to indicate a non-removable device on port 3.	RW	0

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of Companion Controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: there are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.	R	0x1
11:8	N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port Routing Rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.	R	0
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port Power control This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches.	R	1
3:0	N_PORTS	Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved	R	0x00
23:16	ITC	Interrupt Threshold Control  This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined.  0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined	RW	0x08
15:12	RESERVED	Reserved	R	0x0
11	ASPME	Asynchronous Schedule Park Mode Enable  0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous Schedule Park Mode Count  It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule.  Valid values are 0x1 to 0x3. The software must not write a 0 to this bit when Park Mode Enable is a 1 as this may result in undefined behavior.	RW	0x3
7	LHCR	Light Host Controller Reset  It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers.  Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0
6	IAAD	Interrupt on Async Advance Doorbell  This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule.  Write 0x1: Ring the doorbell.  Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0

High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset
5	ASE	Asynchronous Schedule Enable  This bit controls whether the host controller skips processing the asynchronous schedule.  0x0: Do not process the asynchronous schedule 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule.	RW	0
4	PSE	Periodic Schedule Enable  This bit controls whether the host controller skips processing the periodic schedule.  0x0: Do not process the periodic schedule 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule.	RW	0
3:2	FLS	Frame List Size  This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list vurrent index.  0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved	RW	0
1	HCR	Host Controller Reset  This control bit is used by software to reset the host controller. Write  0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values.  This bit is set to 0 by the host controller when the reset process is complete.	W	0
0	RS	Run/stop  0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1.  0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts.	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	Asynchronous Schedule Status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled.	R	0
14	PSS	Periodic Schedule Status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_ <i>[13]</i> PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_ <i>[6]</i> FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_ <i>[1]</i> CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_ <i>[13]</i> PO bit.	RW	0
1	USBEI	USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

## **General-Purpose Interface**

---

---

---

This chapter describes the general-purpose interface for the OMAP34xx multimedia device.

<b>Topic</b>	<b>Page</b>
<b>25.1 General-Purpose Interface Overview .....</b>	<b>3273</b>
<b>25.2 General-Purpose Interface Environment .....</b>	<b>3275</b>
<b>25.3 General-Purpose Interface Integration .....</b>	<b>3278</b>
<b>25.4 General-Purpose Interface Functional Description .....</b>	<b>3285</b>
<b>25.5 General-Purpose Interface Basic Programming Model .....</b>	<b>3289</b>
<b>25.6 General-Purpose Interface Register Manual .....</b>	<b>3295</b>

## 25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pull up/down control, open-drain feature). For more information, see [Chapter 7, System Control Module](#).

### 25.1.1 Global Features

The GPIO modules include the following global features:

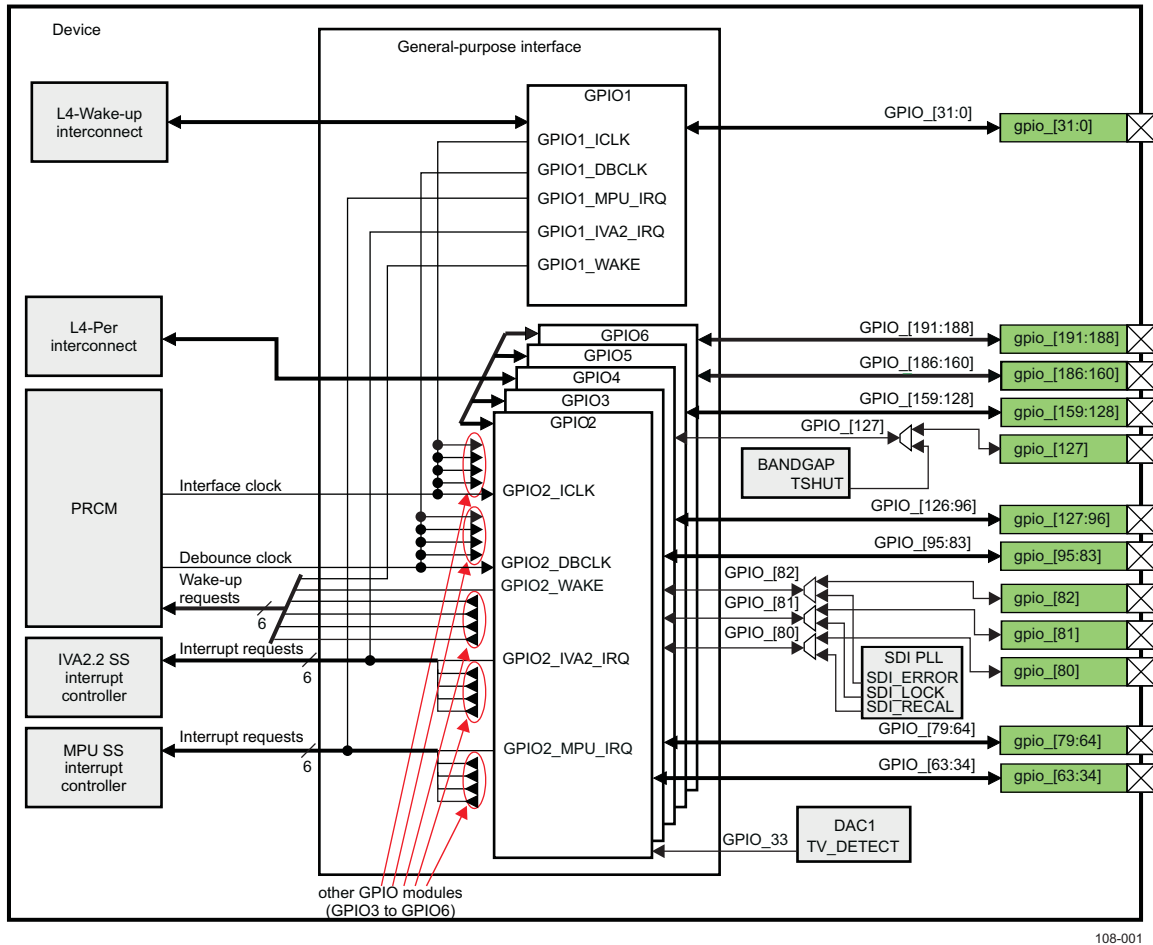

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller and the other on the MPU subsystem interrupt controller.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

[Figure 25-1](#) shows an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

108-001

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO\_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO\_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO\_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO\_DATAOUT
- GPIOi.GPIO\_IRQENABLE1
- GPIOi.GPIO\_IRQENABLE2
- GPIOi.GPIO\_WAKEUPENABLE

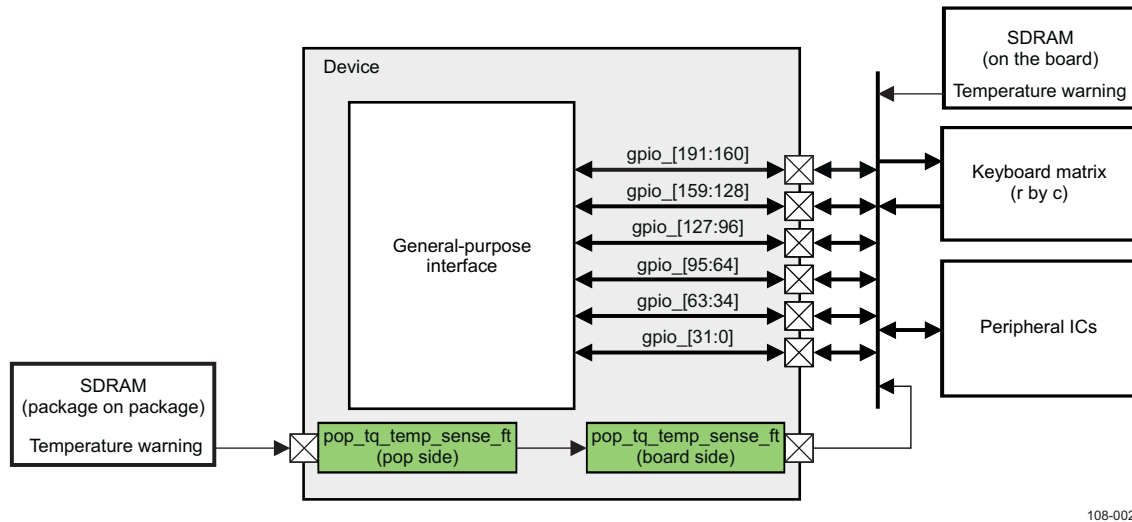

For these registers, the modules implement the set-and-clear protocol register update (see Section 25.5.2, *Set-and-Clear Instructions*).

## 25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

**Figure 25-2. General-Purpose Interface Typical Application System Overview**

108-002

### Note: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the `pop_tq_temp_sense_ft` ball and a GPIO input. To do this, `pop_tq_temp_sense_ft` is connected to a GPIO through the customer board. This feature is application-dependent.

### CAUTION

Due to buffer strength, an external serial resistor must be connected to the balls where `gpio_120` through `gpio_129` are muxed with MMC signals.

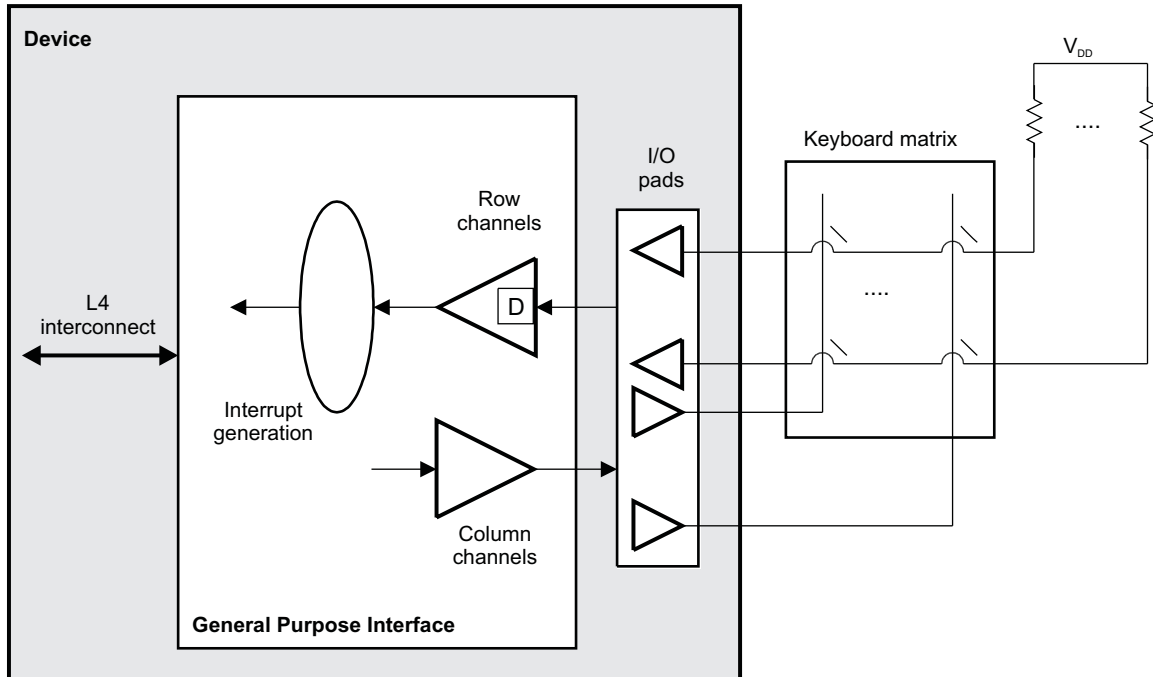

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

### 25.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix ( $r * c$ ). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface

108-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 25.5.3, Interrupt and Wakeup](#)).

When the keyboard interrupt is received, the processor (MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

## 25.2.2 General-Purpose Interface Functional Interfaces

### 25.2.2.1 Basic General-Purpose Interface Pins

Table 25-1 lists the interface pins of the general-purpose interface.

**Table 25-1. General-Purpose Interface Functional Pins Description**

Signal Name	I/O <sup>(1)</sup>	Description <sup>(2)</sup>	Module Reset Value
gpio_[31:0]	I/O	GPIO in configuration mode 4.	Input until software configuration
gpio_[186:34]	I/O	GPIO in configuration mode 4.	Input until software configuration
gpio_[191:188]	I/O	GPIO in configuration mode 4.	Input until software configuration

<sup>(1)</sup> I = Input, O = Output

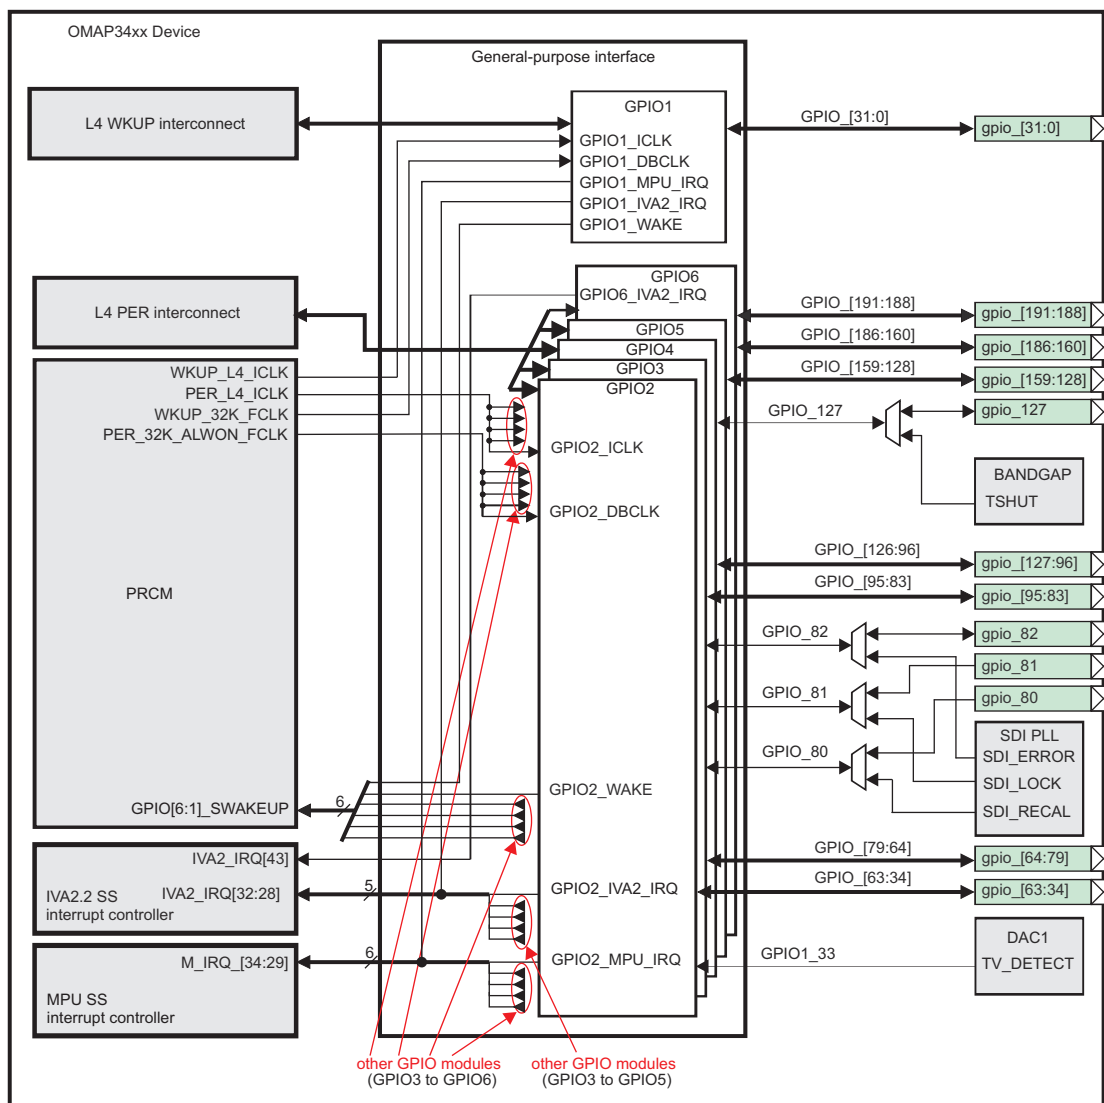

<sup>(2)</sup> See [Chapter 7](#), *System Control Module*, for more information about pin configuration modes.

## 25.3 General-Purpose Interface Integration

### 25.3.1 Description

Figure 25-4 highlights the general-purpose interface integration in the device.

Figure 25-4. General-Purpose Interface Integration Overview

108-004

#### 25.3.1.1 Clocking, Reset, and Power-Management Scheme

##### 25.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, GPIOi\_DBCLK, (where i = 1, 2, 3, 4, 5, and 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

For GPIO2 to GPIO6, this clock is controlled by the EN\_GPIOi (where i = 2 to 6) bit PRCM.CM\_FCLKEN\_PER (0: disabled, 1: enabled the clock). For GPIO1, this clock is controlled by EN\_GPIO1 bit PRCM.CM\_FCLKEN\_WKUP[3] (0: disabled, 1: enabled the clock) for GPIO1.

- Interface clock: The interface clock, GPIOi\_ICLK (where i = 1, 2, 3, 4, 5, and 6), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For GPIO1, this clock is controlled by the EN\_GPIO1 bit PRCM.CM\_ICLKEN\_WKUP[3] (0: disabled, 1:enabled the clock) and AUTO\_GPIO1 bit PRCM.CM\_AUTOIDLE\_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN\_GPIOi (where i = 2 to 6) bit PRCM.CM\_ICLKEN\_PER (0: disabled, 1: enabled the clock) and AUTO\_GPIOi (where i = 2 to 6) bit PRCM.CM\_AUTOIDLE\_PER (enables/disables automatic control of the interface clock). Table 25-2 describes the GPIO module clocks.

**Table 25-2. Clocks**

Attribute	Frequency	Name	Mapping	Comments
Debounce clock	32 KHz	GPIOi_DBCLK, where i = 2 to 6	PER_32K_ALWON_F CLK	Source is PRCM module.
		GPIO1_DBCLK	WKUP_32K_CLK	
Interface clock	Depends on PRCM registers settings	GPIOi_ICLK, where i = 2 to 6	PER_L4_ICLK	
		GPIO1_ICLK	WKUP_L4_ICLK	

### 25.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO6 modules are attached to the PER\_RST reset domain. The GPIO1 module is attached to the WKUP\_RST reset domain.  
The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the RESETDONE bit GPIOi.GPIO\_SYSTATUS[0] monitors the internal reset status; it is set when the reset completes. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one module or more.  
Writing 1 to SOFTRESET bit GPIOi.GPIO\_SYSCONFIG[1](where i = 1, 2, 3, 4, 5, or 6) resets the module. Bit value 1 remains until the reset is complete. When the software reset is complete, the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIOi.GPIO\_SYSTATUS[0] RESETDONE is cleared during a software reset. This bit is set to 1 when the software reset is complete.

### 25.3.1.1.3 Power Domain

The GPIO1 module is attached to the WKUP power domain (see [Chapter 4, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. The GPIO2 to GPIO6 modules are attached to the PER power domain (see [Chapter 4, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

### 25.3.1.1.4 Power Management

#### 25.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi\_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.3.1.2, Hardware Requests](#)).

#### 25.3.1.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

The idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Chapter 4, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.3.1.1.4.3, System Power Management and Wake-up](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO\_CTRL[0] DISABLEMODULE bit (0: the module is enabled and clocks are not gated; 1: the module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

#### 25.3.1.1.4.3 System Power Management and Wake-Up

The PRCM module can require the GPIO modules to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Figure 25-4](#) and [Section 25.3.1.2, Hardware Requests](#)): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode (recommended)

When the GPIO module is configured in smart-idle mode (GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: the corresponding bits in the PRCM.CM\_FCLKEN\_PER and PRCM.CM\_ICLKEN\_PER registers cleared to 0 or the corresponding bit in the PRCM.CM\_AUTOIDLE\_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: PRCM.CM\_FCLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0, PRCM.CM\_ICLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0, or PRCM.CM\_AUTOIDLE\_WKUP[3] AUTO\_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO\_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared) ; and there is no access to GPIO.GPIO\_DEBOUNCINGTIME register pending to be synchronized.

Idle acknowledge is then asserted and the module enters in idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

Idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, the GPIO module exits from idle mode, if the GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled), and the corresponding bit in the PRCM.PM\_WKEN\_PER register is also set to 1 for the GPIO2 to GPIO6 modules, and/or the PRCM.PM\_WKEN\_WKUP[3] EN\_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

When the GPIO module is configured in force-idle mode (GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE field [00]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM\_FCLKEN\_PER and PRCM.CM\_ICLKEN\_PER registers cleared to 0 or the corresponding bit in the PRCM.CM\_AUTOIDLE\_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM\_FCLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0, PRCM.CM\_ICLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0, or PRCM.CM\_AUTOIDLE\_WKUP[3] AUTO\_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO module is configured in no-idle mode (GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE field [01]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM\_FCLKEN\_PER and PRCM.CM\_ICLKEN\_PER registers cleared to 0 or the corresponding bit in the PRCM.CM\_AUTOIDLE\_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM\_FCLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0, PRCM.CM\_ICLKEN\_WKUP[3] EN\_GPIO1 bit cleared to 0 or PRCM.CM\_AUTOIDLE\_WKUP[3] AUTO\_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module does not go to the idle mode and the idle acknowledge is never sent.

---

**Note:** The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM\_IDLEST\_PER register (0: active, 1: idle) and is idle only when the GPIO2 to GPIO6 modules are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM\_IDLEST\_WKUP[3] ST\_GPIO1 bit (0: idle, 1: active) and is idle only when the GPIO1 module is configured in smart-idle mode and has asserted its idle acknowledge.

The GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM\_WKST\_PER register (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM\_WKST\_WKUP[3] ST\_GPIO1 bit (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

---

#### 25.3.1.1.4.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see [Section 25.5.1, Power Saving by Grouping the Edge/Level Detection](#)). All channels are also gated using a one-out-of-N scheme. N is the GATINGRATIO field

GPIOi.GPIO\_CTRL[2:1] and can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO\_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

### 25.3.1.2 Hardware Requests

#### 25.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Table 25-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU subsystem and IVA2.2 subsystem interrupt cont

**Table 25-3. Interrupts**

Name	Mapping	Comments
<b>GPIO1 Module</b>		
GPIO1_MPU_IRQ	M_IRQ_29	Destination is the MPU subsystem interrupt controller.
GPIO1_IVA2_IRQ	IVA2_IRQ[28]	Destination is the IVA2.2 subsystem interrupt controller.
<b>GPIO2 Module</b>		
GPIO2_MPU_IRQ	M_IRQ_30	Destination is the MPU subsystem interrupt controller.
GPIO2_IVA2_IRQ	IVA2_IRQ[29]	Destination is the IVA2.2 subsystem interrupt controller.
<b>GPIO3 Module</b>		
GPIO3_MPU_IRQ	M_IRQ_31	Destination is the MPU subsystem interrupt controller.
GPIO3_IVA2_IRQ	IVA2_IRQ[30]	Destination is the IVA2.2 subsystem interrupt controller.
<b>GPIO4 Module</b>		
GPIO4_MPU_IRQ	M_IRQ_32	Destination is the MPU subsystem interrupt controller.
GPIO4_IVA2_IRQ	IVA2_IRQ[31]	Destination is the IVA2.2 subsystem interrupt controller.
<b>GPIO5 Module</b>		
GPIO5_MPU_IRQ	M_IRQ_33	Destination is the MPU subsystem interrupt controller.
GPIO5_IVA2_IRQ	IVA2_IRQ[32]	Destination is the IVA2.2 subsystem interrupt controller.
<b>GPIO6 Module</b>		
GPIO6_MPU_IRQ	M_IRQ_34	Destination is the MPU subsystem interrupt controller.
GPIO6_IVA2_IRQ	IVA2_IRQ[43]	Destination is the IVA2.2 subsystem interrupt controller.

#### 25.3.1.2.1.1 Wake-Up Generation

The GPIO1 module of the general-purpose interface is attached to the WKUP power domain (see Chapter 4, *Power, Reset, and Clock Management*) and can wake up the system.

**Note:** The GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

**Note:** Only gpio\_1, gpio\_9, gpio\_10, gpio\_11, gpio\_30, and gpio\_31 can be used to generate a direct wake-up event. The other GPIO1 pins cannot be used to generate a direct wake-up event because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is off, the I/O pins of the GPIO1 module, which are supplied by VDD2, cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO\_WAKEUPENABLE register (where i = 1, 2, 3, 4, 5, and 6).

### CAUTION

The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

Table 25-4 shows the wake-up signals mapping.

**Table 25-4. Wake-Up Signals**

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

Table 25-5 describes the GPIO channels.

**Table 25-5. GPIO Channel Description**

Channel Number	Type <sup>(1)</sup>	Mapping	Wake-Up Feature	Comments
<b>GPIO1 Module</b>				
[31:0]	I/O	gpio_[31:0]	Yes	GPIO <sup>(2)</sup>
<b>GPIO2 Module</b>				
[0]	I	-	No	Not available on external balls. Read value is always 0.
[1]	I	TV_DETECT	Yes <sup>(3)</sup>	Internal TV detection signal from the 10-bit composite/luma video DAC1
[31:2]	I/O	gpio_[63:34]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
<b>GPIO3 Module</b>				
[15:0]	I/O	gpio_[79:64]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
[16]	I/O	gpio_80	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
	I	SDI_RECAL	Yes <sup>(3)</sup>	Internal SDI_RECAL signal from the SDI PLL module <sup>(4)</sup>
[17]	I/O	gpio_81	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
	I	SDI_LOCK	Yes <sup>(3)</sup>	Internal SDI_LOCK signal from the SDI PLL module <sup>(4)</sup>

(1) I = Input, O = Output

(2) Configuration mode 4. See [Chapter 7, System Control Module](#).

(3) Only when the PER power domain is active

(4) All configuration modes except configuration mode 4. See [Chapter 7, System Control Module](#).

**Table 25-5. GPIO Channel Description (continued)**

Channel Number	Type <sup>(1)</sup>	Mapping	Wake-Up Feature	Comments
[18]	I/O	gpio_82	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
	I	SDI_ERROR	Yes <sup>(3)</sup>	Internal SDI_ERROR signal from the SDI PLL module <sup>(4)</sup>
[31:19]	I/O	gpio_[95:83]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
<b>GPIO4 Module</b>				
[30:0]	I/O	gpio_[126:96] <sup>(5)</sup>	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
[31]	I/O	gpio_127	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
	I	TSHUT	Yes <sup>(3)</sup>	Internal TSHUT signal from the BANDGAP module for the SRAMs LDOs <sup>(4)</sup>
<b>GPIO5 Module</b>				
[31:0]	I/O	gpio_[159:128]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
<b>GPIO6 Module</b>				
[26:0]	I/O	gpio_[186:160]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>
[27]	I	-	No	Not available on external balls. Read value is always 0.
[31:28]	I/O	gpio_[191:188]]	Yes <sup>(3)</sup>	GPIO <sup>(2)</sup>

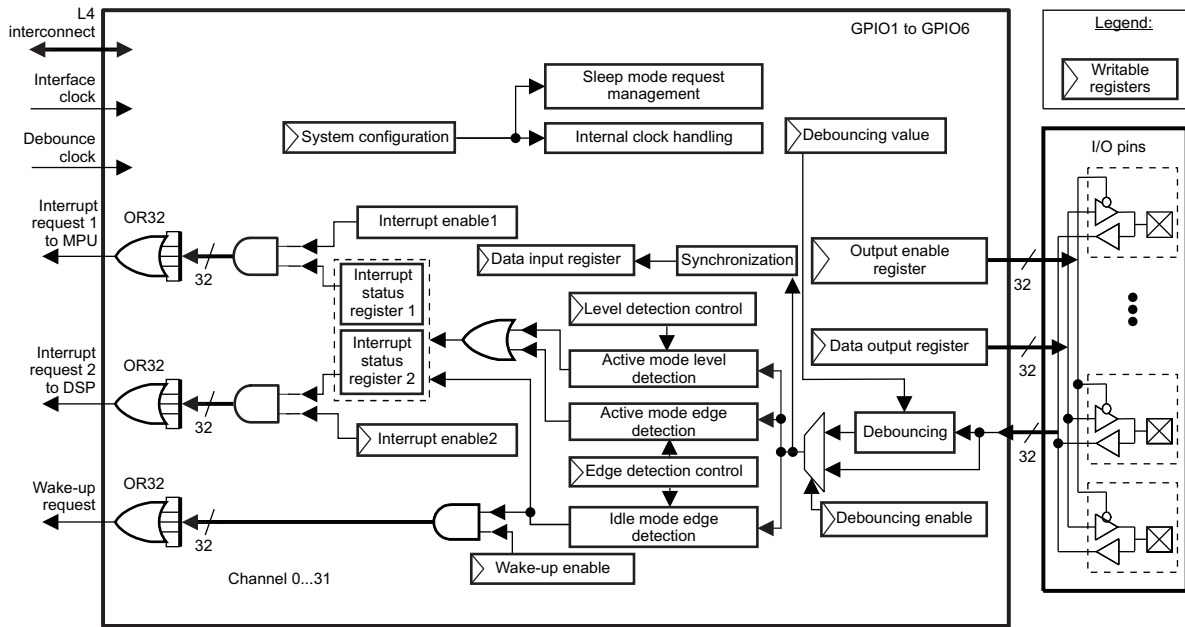

<sup>(5)</sup> All signals are I/O type, except gpio\_99, gpio\_100, gpio\_112, gpio\_113, gpio\_114, and gpio\_115, which are input-only signals.

**Note:** The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 31 of the GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; see [Chapter 7, System Control Module](#), for more information about pin configuration), TSHUT is connected to channel 31 of the GPIO4, and an interrupt can be generated when a low-to-high transition occurs on TSHUT whether or not the interrupt generation for channel 31 of the GPIO4 is correctly configured.

## 25.4 General-Purpose Interface Functional Description

Figure 25-5 shows the general-purpose interface description.

Figure 25-5. General-Purpose Interface Description

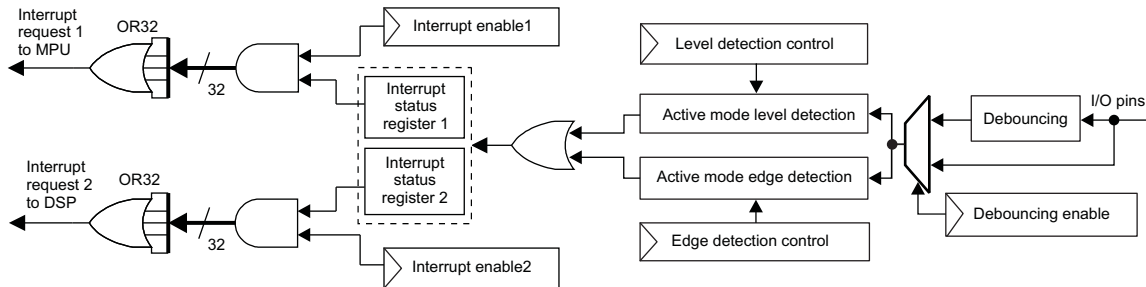

108-005

Figure 25-5 details the GPIO modules in the general-purpose interface block diagram with their configuration registers and their main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2). See Figure 25-6.

Figure 25-6. Synchronous Path

108-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wake-up enable register. See Figure 25-7.

Figure 25-7. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

### 25.4.1 Interrupt and Wake-Up Features

#### 25.4.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi\_MPU\_IRQ (used by the MPU subsystem) and GPIOi\_IVA2\_IRQ (used by the IVA2.2 subsystem), where  $i = 1, 2, 3, 4, 5,$  and  $6$ .

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt enable (GPIOi.GPIO\_IRQENABLE1 or GPIOi.GPIO\_IRQENABLE2) and interrupt status (GPIOi.GPIO\_IRQSTATUS1 or GPIOi.GPIO\_IRQSTATUS2) registers. The interrupt enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 25.5.3, *Interrupt and Wakeup*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 25.3.1.1.4.4, *Module Power Saving*). When an event matches the programmed settings (see Section 25.5.3, *Interrupt and Wakeup*), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals  $N$  times the interface clock period; see Section 25.3.1.1.4.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

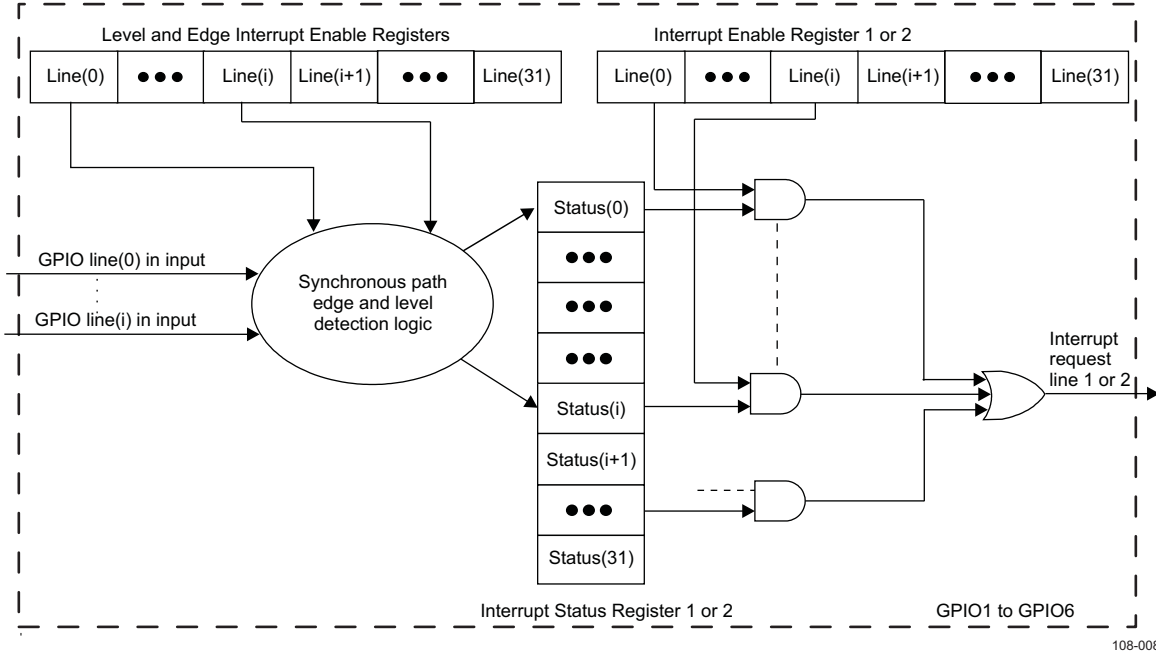

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the debouncing time register (GPIOi.GPIO\_DEBOUNCINGTIME) value (see Section 25.5.5, *Debouncing Time*) and is less than three internally gated interface clock cycles + two interface clock cycle + GPIOi.GPIO\_DEBOUNCINGTIME register value debounce clock cycles + three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.

Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Figure 25-8 shows an overview of the interrupt request generation.

**Figure 25-8. Interrupt Request Generation**

### 25.4.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up enable register (GPIOi.GPIO\_WAKEUPENABLE) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO\_IRQSTATUS1 and GPIOi.GPIO\_IRQSTATUS2).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 25.5.3, *Interrupt and Wakeup*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi\_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6), if the wake-up enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO\_IRQSTATUS1 and GPIOi.GPIO\_IRQSTATUS2). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt enable registers (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2).

---

**Note:** When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

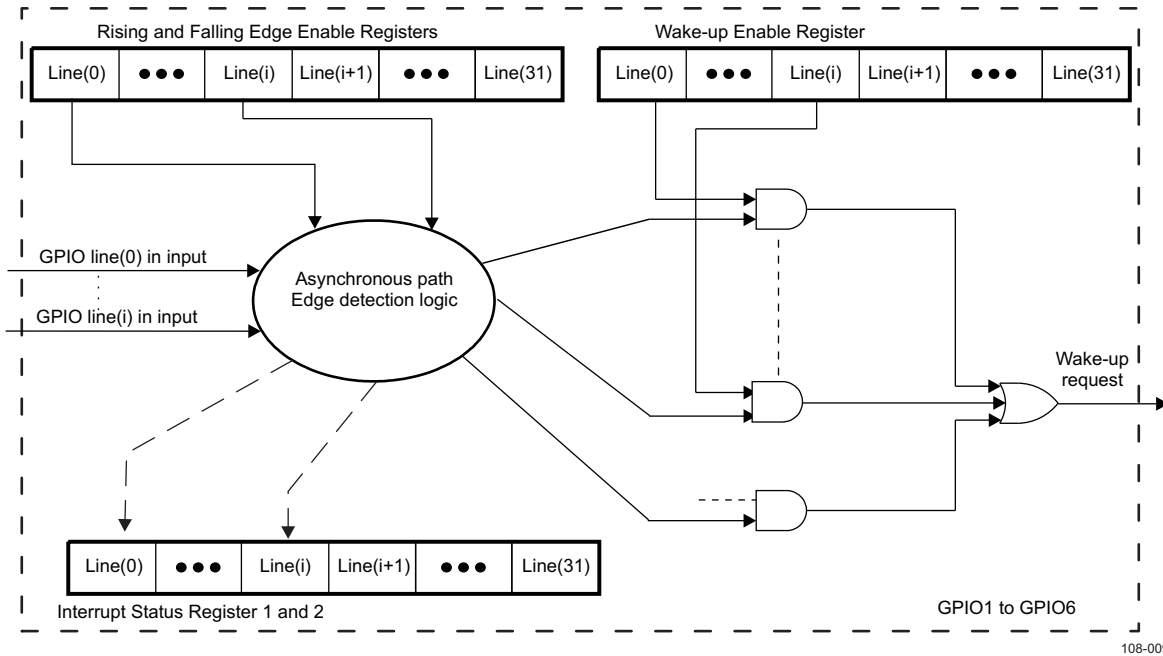

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wake-up enable register (GPIOi.GPIO\_WAKEUPENABLE) has no effect.

---

Figure 25-9 shows an overview of the wake-up request generation.

Figure 25-9. Wake-Up Request Generation

### 25.4.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO\_IRQSTATUS1 or GPIOi.GPIO\_IRQSTATUS2) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt status register. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt enable register are not cleared), the interrupt line is reasserted.

---

**Note:** The status bit must be reset to re-enter idle mode.

---

## 25.5 General-Purpose Interface Basic Programming Model

### 25.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

GPIOi.GPIO\_LEVELDETECT0  
 GPIOi.GPIO\_LEVELDETECT1  
 GPIOi.GPIO\_RISINGDETECT  
 GPIOi.GPIO\_FALLINGDETECT

are set to 0x01 01 01 01, then all clocks are active (power consumption is high).

are set to 0x00 00 00 FF, then a single clock is active (power saving).

---

**Note:** When the clocks are enabled by writing to the GPIOi.GPIO\_LEVELDETECT0, GPIOi.GPIO\_LEVELDETECT1, GPIOi.GPIO\_RISINGDETECT, and GPIOi.GPIO\_FALLINGDETECT registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

---

### 25.5.2 Set-and-Clear Instructions

#### 25.5.2.1 Description

The GPIO module implements the set-and-clear protocol register update for the GPIOi.GPIO\_DATAOUT, GPIOi.GPIO\_IRQENABLE1, GPIOi.GPIO\_IRQENABLE2, and GPIOi.GPIO\_WAKEUPENABLE registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

#### 25.5.2.2 Clear Instruction

##### 25.5.2.2.1 Clear Registers Addresses

Clear interrupt enable registers (GPIOi.GPIO\_CLEARIRQENABLE1 and GPIOi.GPIO\_CLEARIRQENABLE2).

A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register

Clear wake-up enable register (GPIOi.GPIO\_CLEARWКУENA).

A write operation in the clear wake-up enable register clears the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wake-up enable register returns the value of the wake-up enable register.

Clear data output register (GPIOi.GPIO\_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

### 25.5.2.2.2 Clear Instruction Example

Assume the data output register (or one of the interrupt/wake-up enable register) contains the binary value, 0b0000 0001 0000 0001, and you want to clear the bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wake-up enable register). After this write operation, a reading of the data output register (or the interrupt/wake-up enable register) returns 0b0000 0001 0000 0000; the bit 0 is cleared.

**Note:** Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-10 shows an example of a clear instruction.

**Figure 25-10. Write @GPIO\_CLEARDATAOUT Register Example**

108-010

### 25.5.2.3 Set Instruction

#### 25.5.2.3.1 Set Registers Addresses

Set interrupt enable registers (GPIOi.GPIO\_SETIRQENABLE1 and GPIOi.GPIO\_SETIRQENABLE2).

A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

Set wake-up enable register (GPIOi.GPIO\_SETWKUENA).

A write operation in the set wake-up enable register sets the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wake-up enable register returns the value of the wake-up enable register.

Set data output register (GPIOi.GPIO\_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

### 25.5.2.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set the bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; the bits 15, 3, 2, and 1 are set.

---

**Note:** Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

---

Figure 25-11 shows an example of a set instruction.

108-011

The set wake-up enable register offers the same feature with the wake-up enable register.

## 25.5.3 Interrupt and Wakeup

### 25.5.3.1 Involved Configuration Registers

- Interrupt enable registers (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2)  
The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt enable registers are programmed synchronously with the interface clock.  
These registers can be accessed with direct read/write operations or using the alternate set and clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt enable1 (or interrupt enable2) registers (or to the clear interrupt enable1 [or interrupt enable2] registers) address (see [Section 25.5.2, Set-and-Clear Instructions](#)).
- Wake-up enable register (GPIOi.GPIO\_WAKEUPENABLE)  
The wake-up enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.  
This register can be accessed with direct read/write operations or by using the alternate set and clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wake-up enable register (or to the clear wake-up enable register) address (see [Section 25.5.2, Set-and-Clear Instructions](#)).

---

**Note:** It must be a correlation between Wake-up enable and interrupt enable registers. If a GPIO pin has a Wake-up configured on it, it should also have the corresponding interrupt enabled (on one of the 2 interrupt lines). Otherwise, it is possible to have a Wake-up event, but after exiting the Idle state, no interrupt will be generated, thus the corresponding bit from the interrupt status register will not be cleared, and the module will not acknowledge a future Idle Request.

---

- Interrupt status registers (GPIOi.GPIO\_IRQSTATUS1 and GPIOi.GPIO\_IRQSTATUS2)  
The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered

the interrupt line1 (or interrupt line2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wake-up). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected via an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO module is awake.

---

**Note:** The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

---

### 25.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or DSP subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO\_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_LEVELDETECT0), and/or high-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_LEVELDETECT1), and/or rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_RISINGDETECT), and/or falling edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_FALLINGDETECT).

---

**Note:** Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rising detect enabling register (GPIOi.GPIO\_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO\_FALLINGDETECT) along with the interrupt enable by setting the corresponding bit to 1 in on one or both interrupt enable registers (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2).

Enabling at the same time high level detection and low level detection for one given pin makes a constant interrupt generator.

---

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of GPIOi.GPIO\_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of GPIOi.GPIO\_IRQENABLE2 register).

To configure a GPIO module to sent a wake-up request to the PRCM at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO\_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_RISINGDETECT) and/or falling-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO\_FALLINGDETECT). The wake-up request can only be generated on edge transitions.
3. The GPIO channel must be enabled in the wake-up enable register (write 1 to the corresponding bit of the GPIOi.GPIO\_WAKEUPENABLE).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must be enabled for the module (write 1 to the corresponding bit of the GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP) .

**CAUTION**

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in [Chapter 7](#), *System Control Module*.

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO\_IRQSTATUS1 or GPIOi.GPIO\_IRQSTATUS2) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt status register) before enabling an interrupt for the GPIO channel in the interrupt enable register (GPIOi.GPIO\_IRQENABLE1 or GPIOi.GPIO\_IRQENABLE2) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

**25.5.4 Data Input (Capture)/Output (Drive)**

The output enable register (GPIOi.GPIO\_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO\_OE register), the value of the corresponding bit in the GPIOi.GPIO\_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO\_SETDATAOUT) or to the clear output data register (GPIOi.GPIO\_CLEARDATAOUT) address (see [Section 25.5.2](#), *Set-and-Clear Instructions*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO\_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2) registers.

When configured as an input (the desired bit set to 1 in the GPIOi.GPIO\_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO\_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see [Section 25.5.2](#), *Set-and-Clear Instructions*). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO\_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO\_IRQENABLE1 and GPIOi.GPIO\_IRQENABLE2) registers to the interrupt and wake-up feature as needed.

### 25.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO\_OE register)
2. The debouncing time must be set in the debouncing time register (GPIOi.GPIO\_DEBOUNCINGTIME)  
The debouncing value register (GPIOi.GPIO\_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO\_DEBOUNCINGTIME[7:0] DEBOUNCVAL field value + 1) x 31  $\mu$ s.

where GPIOi.GPIO\_DEBOUNCINGTIME[7:0] field DEBOUNCVAL value is from 0 to 255.

3. The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding bit of the GPIOi.GPIO\_DEBOUNCENABLE register)

## 25.6 General-Purpose Interface Register Manual

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

Table 25-6 shows the base address and address space for the GPIO module instances.

**Table 25-6. Instance Summary**

Module Name	Base Address	Size
GPIO1	0x4831 0000	4K bytes
GPIO2	0x4905 0000	4K bytes
GPIO3	0x4905 2000	4K bytes
GPIO4	0x4905 4000	4K bytes
GPIO5	0x4905 6000	4K bytes
GPIO6	0x4905 8000	4K bytes

### 25.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 25-7 through Table 25-8 describe the GPIO register offset addresses.

**Table 25-7. GPIO1 to GPIO3 Register Summary**

The write latency for all the R/W registers is immediate (with respect to the interface clock)

**Note:** When two write accesses in the GPIOi.GPIO\_DEBOUNCINGTIME register are performed in less than two debounce clock cycles (32 kHz) + four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, one bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

## 25.6.2 Register Descriptions

Table 25-9 through Table 25-59 describe the register bits.

<b>26.6 Debug Configuration .....</b>	<b>3382</b>

## 26.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the OMAP34xx device from power on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavior expectations.

### 26.1.1 Terminology

- Bootstrap: Initial software (SW) launched by the ROM code during the memory booting phase
- Certificate: Data block plus trusted signature of the data block
- Downloaded software: Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- eFuse: A one-time programmable memory location usually set at the factory
- Flash loader: Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- GP device: General-purpose device
- Initial software: Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- Memory booting: ROM code mechanism that consists of executing initial software from external memory
- Peripheral booting: ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- Permanent booting device: Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- Preflashing: A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- R&D certificate: Certificate where the data block contains development configuration parameters
- ROM code: The on-chip software in OMAP™ ROM that implements booting

### 26.1.2 Initialization Process

Figure 26-1 is an overview of the initialization process and its steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader
- OS/application

Each step, up to OS/applications running, is explained in the following sections.

**Figure 26-1. Initialization Process**

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring those system interface pins (balls on the device) that have software-configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers that are vital for correct device initialization.

## 26.2 Preinitialization

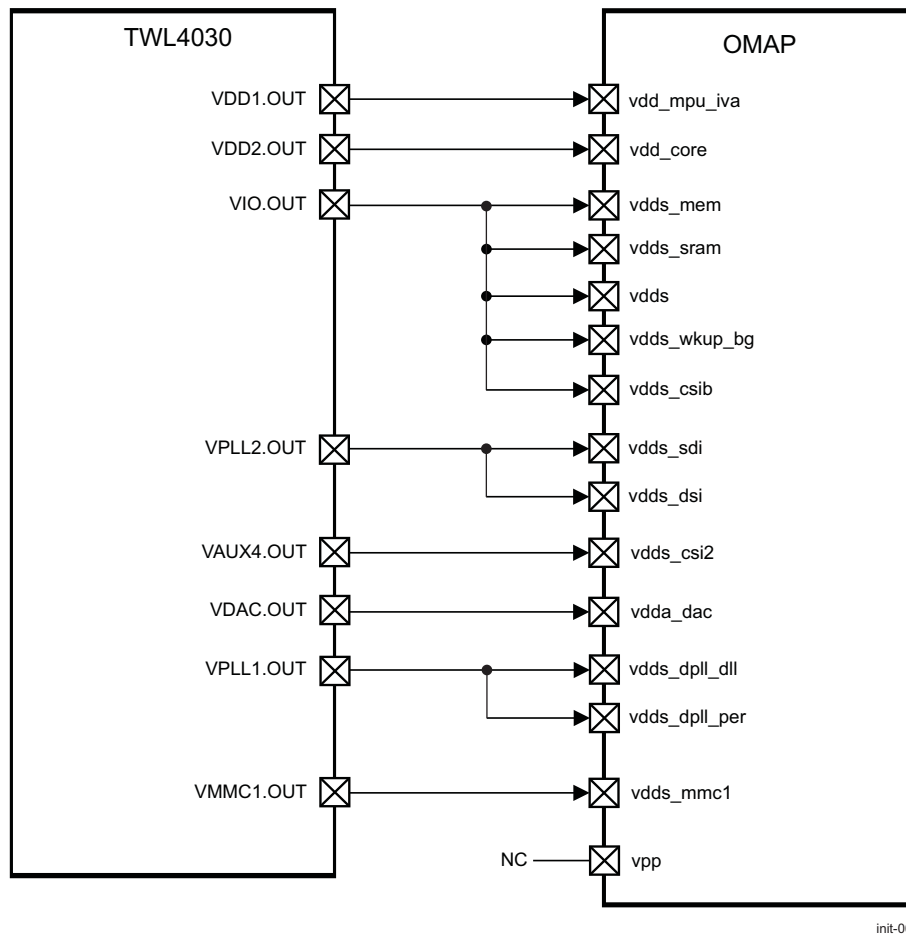

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven correctly for successful device initialization. The following sections describe the specific requirements for the preinitialization stage.

### 26.2.1 Power Connections

The device can be supplied by an external power integrated circuit (IC). TI provides a global solution with the OMAP34xx connected to the TWL4030 power IC.

Figure 26-2 shows the power connections between the OMAP34xx and the TWL4030 power IC.

Figure 26-2. OMAP34xx and TWL4030 Power Connections

init-002

**Note:** Figure 26-2 is an example of power connections between the OMAP3430 device and the TWL4030. These connections depend on the application: For example, if a serial display or camera interface is used, it must be supplied by the low-dropout (LDO) regulator (low noise).

**Notes:**

- The sys\_clkout output clock cannot be provided to peripherals when the core is off.
- The sys\_clkreq output signal switches the system clock on or off.
- After power-on reset (POR), the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys\_boot[6] pin.

Table 26-1 describes the power pins.

**Table 26-1. Power Pins<sup>(1)</sup>**

OMAP34xx Input/Output (I/O) Voltage Name	Description
vdd_mpu_iva	MPU and image and video accelerator (IVA) subsystem power supply
vdd_core	Core power supply
vdds	I/O power supply
vdds_mem	Memory I/O power supply
vdds_wkup_bg	Wake-up LDO and VDDA (2LDO SRAM and ball grid [BG]) power supply
vdds_sram	SRAM LDO power supply
vdds_dppll_dll	Power supply for three phase-locked loop (3PLL) (1.8 V)
vdds_dppll_per	Peripheral digital phase-locked loop (DPLL) power supply
vdds_sdi	Dedicated power supply for serial display interface (SDI) I/O cell
vdds_csi2	Dedicated power supply for CSI2 Complex I/O
vdds_csib	Dedicated power supply for CS1b Complex I/O
vdds_dsi	1.8-V analog power supply
vdda_dac	Video digital-to-analog converter (DAC) power supply
vdds_mmc1	Power supply for multimedia card (MMC) and secure digital (SD) interfaces
vpp	eFuse programming

<sup>(1)</sup> The OMAP34xx package-on-package (POP) device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. The correct power supply to the feedthroughs must be provided based on memory requirements.

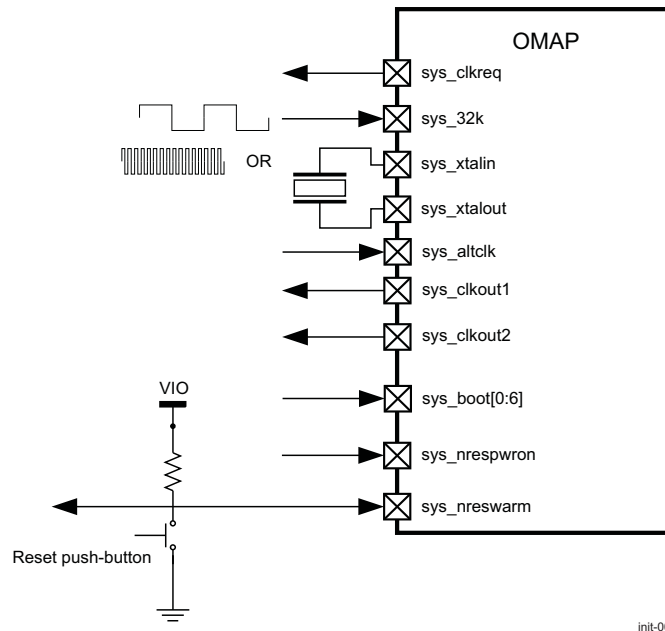

For more information about power management, see [Chapter 4, Power, Reset, and Clock Management](#).

## 26.2.2 Clock and Reset

### 26.2.2.1 Clock and Reset Overview

Figure 26-3 shows the clock and reset environment that gathers the clocks and reset signals related at the system level, as well as system expansion signals.

Figure 26-3. Clock and Reset Environment

The main features of the system interface are:

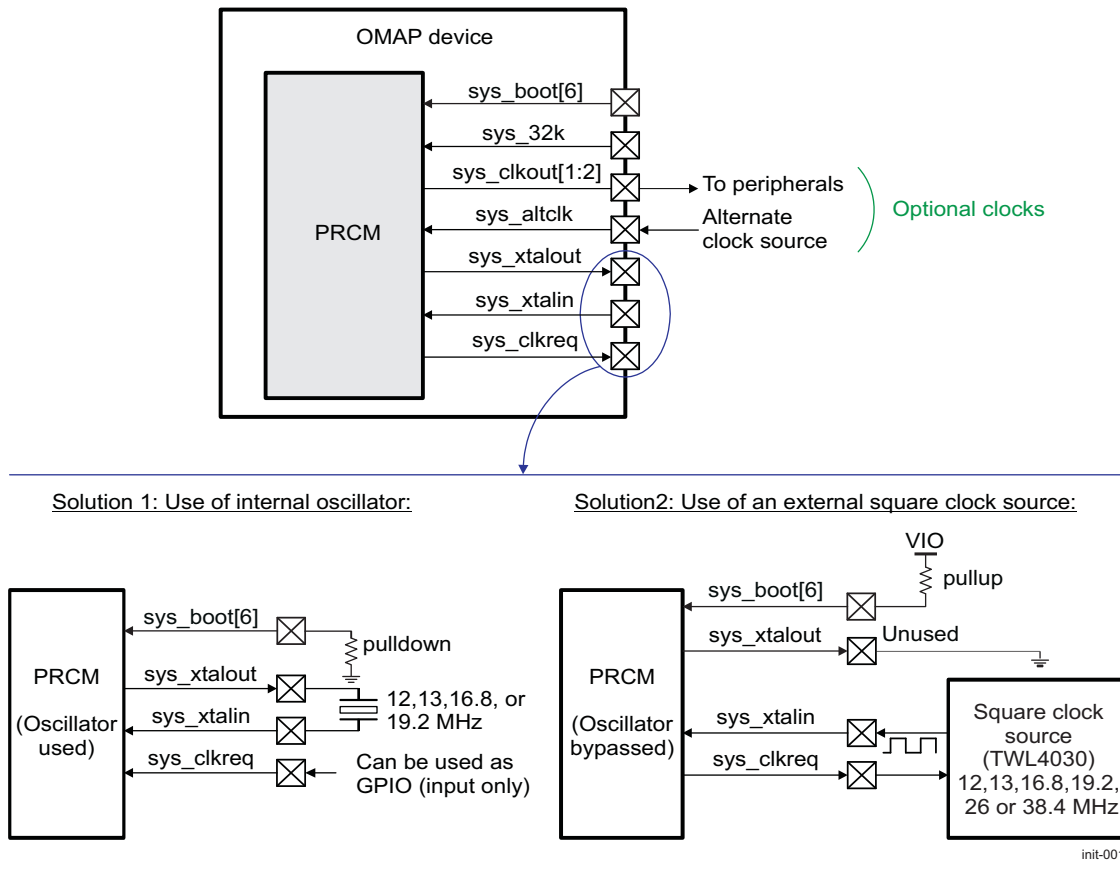

- A clock request output to an external square clock source
- 12, 13, 16.8, 19.2, 26, or 38.4-MHz reference clock input from the external crystal oscillator (only 12, 13, 16.8, or 19.2 MHz) or the digital clock input (all frequencies)
- 32-kHz CMOS clock input
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Seven input signals to define the boot mode
- Two reset sources
  - POR (cold reset)
  - Bidirectional warm reset

## 26.2.2.2 Clock Configuration

### 26.2.2.2.1 Required System Input Clocks

Figure 26-4 shows the clock interface.

**Figure 26-4. Clock Interface**

**Notes:**

- The sys\_clkout output clock cannot be provided to peripherals when the core is off.
- The sys\_clkreq output signal switches the system clock on or off.
- After POR, the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys\_boot[6] pin.

The device operation requires two external input clocks, as follows:

- sys\_32k: The 32-kHz frequency is used for low-frequency operation.
- sys\_xtal (in/out): The system clock is the main clock source of the device. The system clock input can be connected in either of two ways:
  - Crystal quartz through the sys\_xtalin and sys\_xtalout pins, using an internal oscillator up to 19.2 MHz
  - Complementary metal oxide semiconductor (CMOS) digital clock (square clock) through the sys\_xtalin pin. The oscillator is bypassed.

Table 26-2 lists the mapping for input sources.

**Table 26-2. Mapping For Input Sources**

Input Source	Mapping	Frequencies	Comment
Crystal quartz	sys_xtalin and sys_xtalout	12, 13, 16.8, or 19.2 MHz	Requires use of internal oscillator
Square clock (1.8 CMOS signal)	sys_xtalin (sys_xtalout unconnected)	12, 13, 16.8, 19.2, 26, or 38.4 MHz	Internal oscillator is bypassed.

Because sys\_32k, sys\_xtalin, and sys\_xtalout have permanently assigned pin locations with no pad configuration for these pins through a system control module (SCM) register, only one source input at a time can be used.

#### 26.2.2.2 Optional System Input Clock: *sys\_altclk*

An additional clock can be provided through the sys\_altclk input pin to supply internal peripherals, PLLs, a precise clock for National Television System Committee (NTSC) standard (54 MHz), and a universal serial bus (USB) full-speed (FS) controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the SCM CONTROL.CONTROL\_PADCONF\_I2C3\_SDA register. As an example, to use the sys\_altclk pin, the CONTROL.CONTROL\_PADCONF\_I2C3\_SDA[18:16] MUXMODE1 bit field must be set to 0x01.

#### 26.2.2.3 Optional System Output Clock: *sys\_clkout1* and *sys\_clkout2*

Two output clocks (sys\_clkout1 and sys\_clkout2 pins) are available:

- sys\_clkout1 can output the oscillator clock. Its OFF state polarity is programmable.
- sys\_clkout2 can output the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. sys\_clkout2 can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

#### CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

The clocks can be managed by software with the appropriate register in the power, reset, clock, management (PRCM) module:

- sys\_clkout1 is managed using PRCM.PRM\_CLKOUT\_CTRL and PRCM.PRM\_POLCTRL[2].
- sys\_clkout2 is managed using PRCM.CM\_CLKOUT\_CTRL and PRCM.CM\_CLKSEL1\_PLL[28:27].

#### 26.2.2.3 Reset Configuration

The sys\_nrespwron reset pin resets the entire chip during POR.

The sys\_nreswarm reset pin resets the entire chip when the device is supplied and operating, except for the following:

- Part of synchronous dynamic RAM (SDRAM) controller (SDRC)
- Part of IVA
- Part of PRCM
- Control module
- Watchdog
- 32-kHz synchronization timer
- DPLLs

**CAUTION**

sys\_nrespwrn must be driven low during a power-up sequence.

sys\_nreswarm is a bidirectional reset. When an internal reset occurs, sys\_nreswarm goes low and resets all the peripherals. The sys\_nreswarm output is open-drain; consequently, an external pullup resistor is required.

sys\_nrespwrn and sys\_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM\_RSTST\_MPU register and used by the boot ROM code.

### 26.2.3 Boot Configuration

Six external pins (sys\_boot[5:0]) are used to select interfaces or devices for booting. The sys\_boot[6] pin is used to select whether the internal oscillator is bypassed.

These seven pins are sampled and latched onto the CONTROL.CONTROL\_STATUS register after POR. After booting, these pins can be used for other functions and the associated CONTROL.CONTROL\_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see [Chapter 7, System Control Module](#).

---

**Note:** If used as GPIOs, these pins must be used in output mode. To ensure that the sys\_boot[6:0] input values are selected by the pullup and pulldown on sys\_boot[6:0] pins at POR, these GPIOs must be used only in output mode. Because these balls have no pullup or pulldown capacity, care must be taken when choosing to use these GPIOs.

---

[Table 26-3](#), [Table 26-4](#), and [Table 26-5](#) are decoding tables for sys\_boot pins. Depending on sys\_boot pin configuration during the reset (leftmost column), the ROM code tries to boot on the first device listed. If the boot fails on this first device, the ROM code tries the second device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
  - Execute in place (XIP): XIP memory without wait monitoring enabled (NOR flash memories)
  - XIP wait: XIP memory with wait monitoring
  - DOC: DiskOnChip™ memory (H3 device types)
  - NAND: NAND flash memories (non-XIP)
  - OneNAND: OneNAND flash memories
  - MMC1: MMC or SD flash cards with active primary partition of type file allocation table (FAT)12/16/32 connected to the first MMC/SD/secure digital input/output (SDIO)1 card interface
  - MMC2: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the second MMC/SD/SDIO2 card interface
- Peripheral interfaces:
  - USB: High-speed (HS) USB
  - UART3: UART interface
- Permanent booting devices are in *italics*.

[Table 26-3](#) and [Table 26-4](#) list the sys\_boot pin configuration after a POR.

**CAUTION**

- • UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- • HS USB boot: If TWL4030 or TWL5030 processor is used as the USB transceiver, it must be connected to the OMAP3430 through I2C1. No other I<sup>2</sup>C interface allows the necessary TWL processor configuration.

## 26.3 Power, Clocks, and Reset Power-Up Sequence

See [Chapter 4, Power, Reset, and Clock Management](#), section *Power-Up Sequence*, for the power-on sequence, including power supplies, clocks, and reset signals.

For further information regarding the device power-up sequence, refer to the OMAP34xx Data Manual, available through your TI representative.

## 26.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

### 26.4.1 Booting Overview

#### CAUTION

To use the level 2 (L2) cache with the OMAP34xx device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

#### 26.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting memories.

The ROM code has two functionalities for booting: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (HS USB or UART 3) by using the sys\_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

[Table 26-6](#) lists the pin multiplexing according to boot peripheral.

**Table 26-6. Pin Multiplexing According to Boot Peripheral**

Boot Device	Pins
NAND/OneNAND	General-purpose memory controller (GPMC) pins in mode 0
XIP memory	GPMC pins in mode 0
DiskOnChip	GPMC pins in mode 0
MMC/SD1	MMC1 pins in mode 0
MMC/SD2	MMC2 pins in mode 0
UART3	UART3 pins in mode 0
HS USB	HSUSB0 pins in mode 0

**CAUTION**

- • UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- • HS USB boot: If TWL4030 or TWL5030 processor is used as the USB transceiver, it must be connected to the OMAP3430 through I2C1. No other I<sup>2</sup>C interface allows the necessary TWL processor configuration.

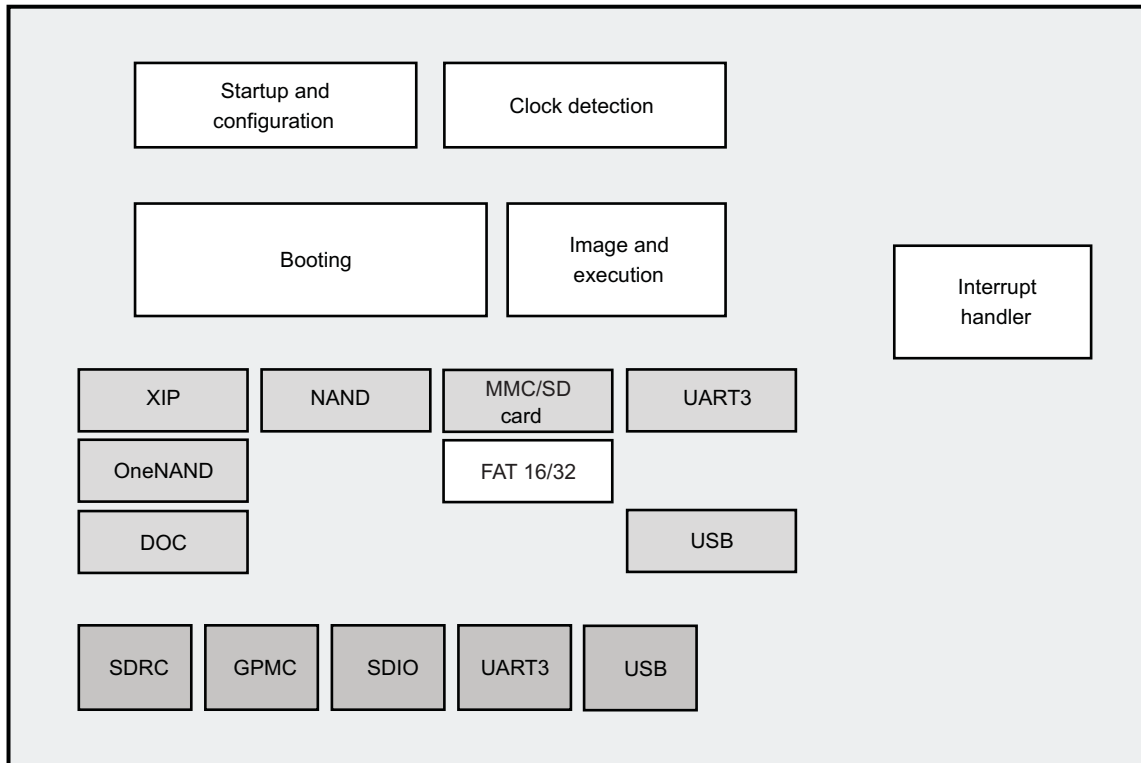

**26.4.1.2 Main Features**

The ROM code architecture is shown in [Figure 26-5](#). The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control to the booting module.
- The clock detection module supports startup by detecting the system clock frequency.
- The booting module uses several device drivers to boot from an external device.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers, which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used by all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

[Figure 26-5](#) shows each module.

Figure 26-5. ROM Code Architecture

- Device drivers 
- Interface drivers 
- Other modules 

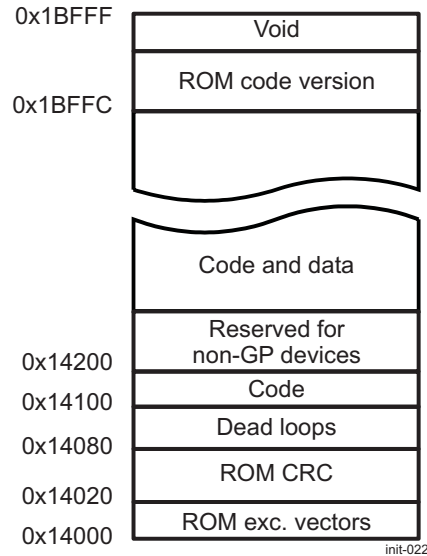

init-006

## 26.4.2 Memory Map

### 26.4.2.1 ROM Memory Map

Figure 26-6 shows the ROM memory map.

**Figure 26-6. 32KB ROM Memory Map**

- ROM exception vectors  
Exceptions are redirected to ROM exception vectors (see [Table 26-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

**Table 26-7. ROM Exception Vectors**

Address	Exception	Content
14000h	Reset	Branch to the public ROM code startup
14004h	Undefined	PC = 4020FFC8h
14008h	Software interrupt (SWI)	PC = 4020FFCCh
1400Ch	Prefetch abort	PC = 4020FFD0h
14010h	Data abort	PC = 4020FFD4h
14014h	Unused	PC = 4020FFD8h
14018h	IRQ	PC = 4020FFDCh
1401Ch	FIQ	PC = 4020FFE0h

- ROM code cyclic redundancy check (CRC)  
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h–1BFFFh. The 4-byte CRC code is stored at location 14020h, which is filled with FFFFFFFFh before the CRC is calculated.
- Dead loops  
Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 26-8](#)).

**Table 26-8. Dead Loops**

Address	Purpose
14080h	Undefined exception default handler
14084h	SWI exception default handler
14088h	Prefetch abort exception default handler
1408Ch	Data abort exception default handler
14090h	Unused exception default handler
14094h	IRQ exception default handler
14098h	FIQ exception default handler
1409Ch	Validation tests Pass
140A0h	Validation tests Fail
140A4h	Bootting failed: No more devices
140A8h	Image not executed or returned
140ACh	Reserved
140B0h	Reserved
140B4h	Reserved
140B8h	Reserved
140BCh	Reserved

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code  
This space is used to keep code.
- Code and data  
This space is used to keep code and other data.
- ROM code version

The ROM code version consists of two decimal numbers: major and minor. The major number is always 14. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 14.04 is coded as a 3-bit word: 00001404h).

### 26.4.2.2 RAM Memory Map

Figure 26-7 shows the RAM memory map. The partitioning of the on-chip SRAM shown in Figure 26-7 is used only during the booting process.

**Figure 26-7. 64KB RAM Memory Map of GP Devices**

- Downloaded image  
This space is used by the public ROM code to store a downloaded booting image.
- Public stack  
This space is reserved for stacks.
- Tracing data  
The public ROM code tracing data is described in Table 26-9. More information about ROM code tracing can be found in Section 26.4.9, *Tracing*.

**Table 26-9. Tracing Data**

Address	Size [Bytes]	Description
0x4020FFB0	4	Current tracing vector, word 1
0x4020FFB4	4	Current tracing vector, word 2
0x4020FFB8	4	Current copy of the PRM_RSTST register (reset reasons)
0x4020FFBC	4	Cold reset run tracing vector, word 1
0x4020FFC0	4	Cold reset run tracing vector, word 2
0x4020FFC4	4	Reserved

- RAM exception vectors  
The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. Table 26-10 shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions that load into the PC the value in the next seven addresses. These instructions are executed when an exception occurs, because they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to another handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

**Table 26-10. RAM Exception Vectors**

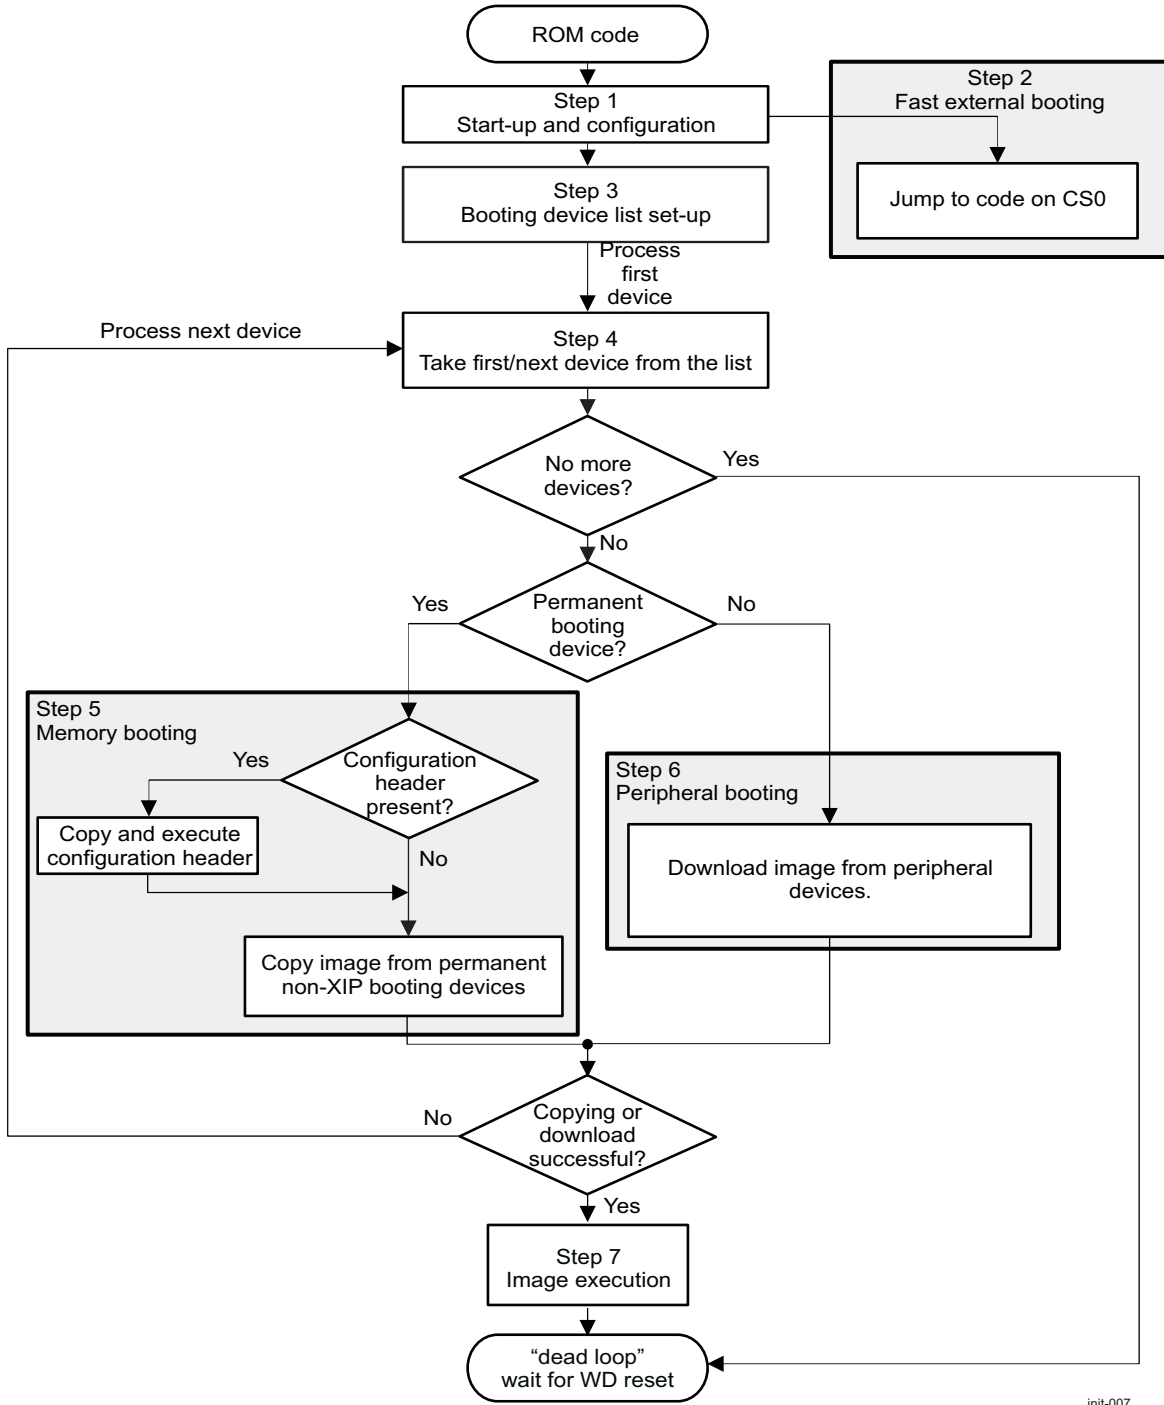

<b>Address</b>	<b>Exception</b>	<b>Content</b>
0x4020FFC8	Undefined	PC = [0x4020FFE4]
0x4020FFCC	SWI	PC = [0x4020FFE8]
0x4020FFD0	Prefetch abort	PC = [0x4020FFEC]
0x4020FFD4	Data abort	PC = [0x4020FFF0]
0x4020FFD8	Unused	PC = [0x4020FFF4]
0x4020FFDC	IRQ	PC = [0x4020FFF8]
0x4020FFE0	FIQ	PC = [0x4020FFFC]
0x4020FFE4	Undefined	0x14080
0x4020FFE8	SWI	0x14084
0x4020FFEC	Prefetch abort	0x14088
0x4020FFF0	Data abort	0x1408C
0x4020FFF4	Unused	0x14090
0x4020FFF8	Interrupt request (IRQ)	0x14094
0x4020FFFC	Fast interrupt request (FIQ)	0x14098

### 26.4.3 Overall Booting Sequence

Figure 26-8 is the ROM code flow chart.

Figure 26-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configurations and initializations.
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.
- Step 3. A booting device list is created (see [Section 26.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys\_boot pins and the software booting configuration described in [Section 26.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the scratchpad memory and can be written by software before executing a software reset. The scratchpad memory is an internal RAM memory that keeps its contents after software reset or wakeup, but not after POR. After a software reset, the software booting configuration has priority over the sys\_boot pin configuration.
- Step 4. After the booting device list is set, the booting procedure examines the devices on the list serially and executes memory booting or peripheral booting, depending on current booting device type:
  - Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip, OneNAND, or MMC/SD cards.
  - Peripheral booting is executed when device is temporary: UART or USB.
- Step 5. Memory booting reads data from memory type devices. Memory booting is described in detail in [Section 26.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the OMAP device sends an ASIC ID structure to inform the host about the peripheral booting start. The host responds by sending a booting message that can have one of three meanings:
  - Skip peripheral booting.
  - Continue peripheral booting.
  - Change the booting device.

If the message is to continue, the host sends the entire image preceded by its size. Peripheral booting is described in [Section 26.4.5, Peripheral Booting](#).

- Step 7. For this device, the image is automatically started.

An additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from the selected permanent device. The CH, which is optional, is described in [Section 26.4.8.2, CH](#).

## 26.4.4 Startup and Configuration

### 26.4.4.1 Startup

The ROM code starts at address 0x0001 4000.

### 26.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 13 Mhz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DLLs required for ROM code execution.

The configured DLLs are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks
- MPU DPLL, set to provide 48 MHz for the Ferrari MPU
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output

The multipliers and dividers of the DPLLs are set to values which depend on the input clock detected.

Table 26-11 summarizes the ROM code default settings for key clocks.

**Table 26-11. ROM Code Default Clock Settings**

<b>Clock</b>	<b>Frequency [MHz]</b>	<b>Source</b>
CORE.CLK	192	CORE DPLL output
L3x2.CLK	192	CORE.CLK
L3.ICLK	96	CORE.CLK/2
L4.ICLK	48	L3.ICLK/2
RM clock	24	L4.ICLK/2
MPU	48	CORE.CLK/4 (MPU DPLL in bypass)

The DPLLs and other settings are configured by default after each type of reset to give the ROM code the same working conditions. However, it is possible to override the default clock settings by means of the software booting configuration; for details, see [Section 26.4.4.4, Software Booting Configuration](#).

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph
- Software booting configuration after a software reset, described in [Section 26.4.4.4, Software Booting Configuration](#)
- CH, described in [Section 26.4.8.2, CH](#). This configuration can be blocked by the software booting configuration; this is possible during the memory booting. The CH lets the user have a known configuration (about GPMC, SDRC, and clock registers) after memory booting.

### 26.4.4.3 Booting Device List Setup

The ROM code creates a device list based on two sources:

- The software booting configuration is stored in nonvolatile RAM memory called scratchpad memory.
- The sys\_boot[5:0] pins are used to index the device table from which the list of devices is extracted.

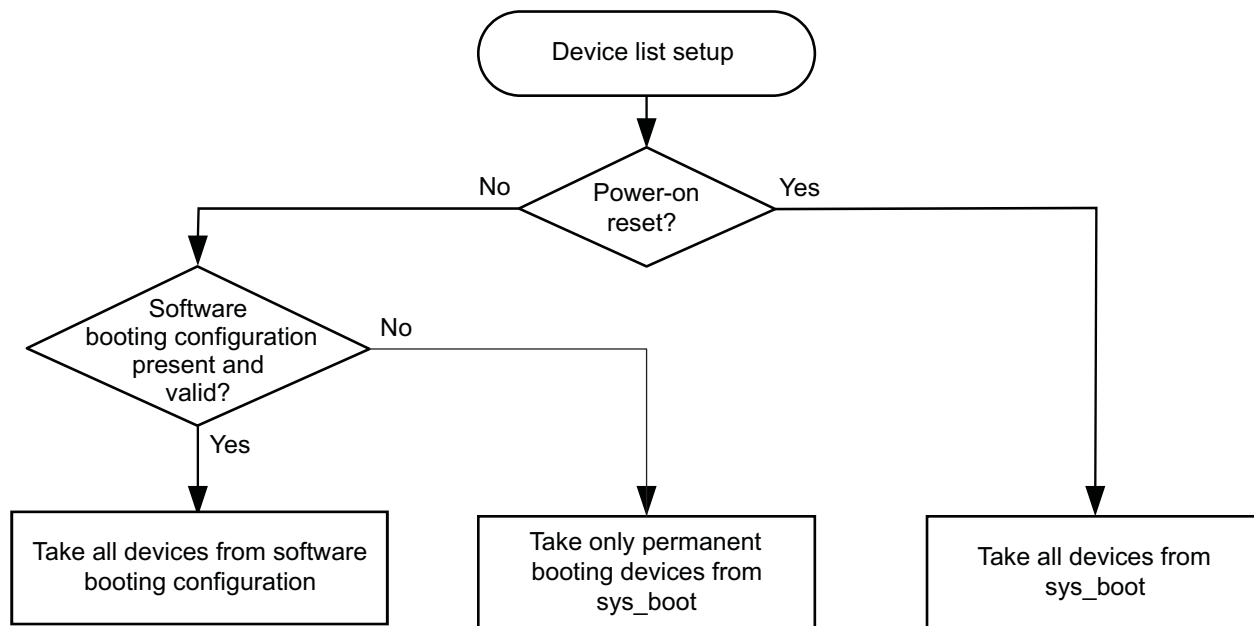

[Figure 26-9](#) shows how the ROM code sets up the device list depending on the reset source.

---

**Note:** Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys\_boot pins. Users can force peripheral booting after software reset using software booting configuration.

---

Figure 26-9. Device List Setup

init-008

26.4.4.4 Software Booting Configuration

The software booting configuration is stored in the special scratchpad memory, which is not cleared after software resets or wakeups. The software booting configuration is a simple structure at the address stored at the first location of available scratchpad memory: 0x48002910. Table 26-12 shows the software booting configuration. There are two sections in this structure:

- The first section provides devices for the booting device list.
- The second section provides clock settings, which are applied before booting.

The sections are not mandatory and their order is not important. The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Table 26-12. Software Booting Configuration Structure

Field	Size [bytes]	Description
<b>Booting Configuration</b>		
Section 1 key	4	Synchronization key for section 1: 0xCF00AA01
Section 1 size	4	Size of section 1: 0x0000000C (12)

## 26.4.5 Peripheral Booting

### 26.4.5.1 Overview

The ROM code can boot from different peripherals:

- HS USB: HS USB interface
- UART 3: Baud rate 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is used primarily for programming flash memories connected to the OMAP device. The protocol is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in [Figure 26-10](#).

**Figure 26-10. Common Peripheral Booting Protocol**

The ROM code first initializes the interface and sends a message called ASIC ID to a host. The content of this message is summarized in [Table 26-13](#). The host uses this message to send only appropriate data to the OMAP device according to the identification codes sent.

The ROM code waits 300 ms for an answer from the host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

**Table 26-13. ASIC ID Structure**

ASIC ID Item	Size [Bytes]	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information

**Table 26-13. ASIC ID Structure (continued)**

ASIC ID Item	Size [Bytes]	Description
Reserved for non-GP devices	4	Reserved
ID subblock	23	Identification data
Reserved for non-GP devices	23	Reserved
Checksum subblock	11	CRC (4 bytes)

The host can send different messages, as described in [Table 26-14](#). If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

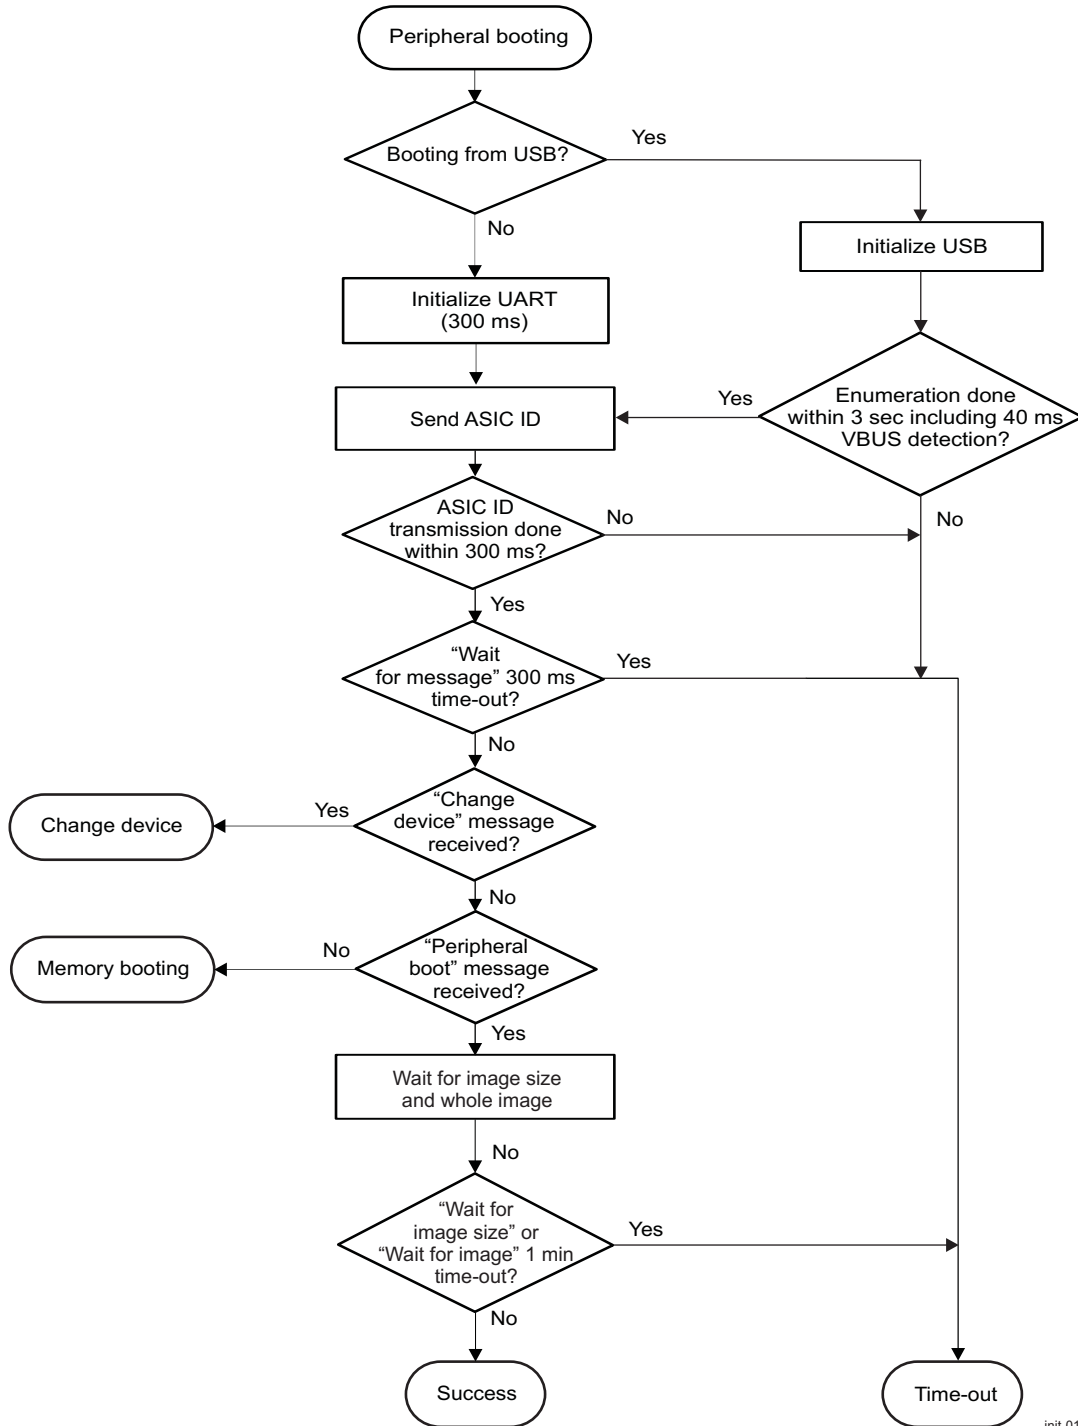

The ROM code waits up to 1 minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

**Table 26-14. Boot Messages**

Message Name	Value	Description
Peripheral boot	0xF0030002	Continue peripheral booting.
Change device	0xF003XX06	Skip current peripheral booting and continue booting from device type indicated by XX: 0x00: Void, no device 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x08..0x0F: Reserved 0x10: UART 0x11: HS USB Others: Reserved
Next device	0xFFFFFFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 26-11 shows the peripheral booting procedure.

**Figure 26-11. Peripheral Booting Procedure**

init-010

### 26.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX with software flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART time-out is 300 ms.

### 26.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface
- USB 2.0 transceiver macrocell interface (UTMI)+ low pin interface (ULPI) 8-bit data transceiver support (single data rate)
- TWL4030 device detection and automatic configuration of its USB transceiver using I2C1
- The enumeration time-out is 3 seconds.

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

HS USB peripheral booting with a cellular systems software tool (CSST) is possible with a software development platform (SDP). The user can download CSST on [www.ti.com](http://www.ti.com) (Wireless Handset Solution > OMAP Platform > Development Tools).

#### 26.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor. Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required. [Table 26-15](#) describes the device descriptors.

**Table 26-15. Device Descriptor**

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0

**Table 26-15. Device Descriptor (continued)**

Field	Value	Description
idVendor	0x0451	Vendor ID
idProduct	0xD009	Product ID
bcdDevice	0x0000	Device release number
iManufacturer	See values in <a href="#">Section 26.4.5.3.2</a> .	Index of string descriptor describing manufacturer
iProduct	See values in <a href="#">Section 26.4.5.3.2</a> .	Index of string descriptor describing product
iSerialNumber	See values in <a href="#">Section 26.4.5.3.2</a> .	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- **Device-qualifier descriptor**  
The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 26-16](#) describes a device-qualifier descriptor.

**Table 26-16. Device-Qualifier Descriptor**

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- **Configuration descriptor**  
This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See [Table 26-17](#) for details.

**Table 26-17. Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- **Other speed configuration descriptor**  
This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See [Table 26-18](#) for details.

**Table 26-18. Other Speed Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

This descriptor describes a specific interface in a configuration. See [Table 26-19](#) for details.

**Table 26-19. Interface Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See [Table 26-20](#) and [Table 26-21](#) for details.

**Table 26-20. BULK IN Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

**Table 26-21. BULK OUT Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors
 

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device. See the tables describing string descriptors:

  - The language ID string descriptor (Table 26-22)
  - The manufacturer ID string descriptor (Table 26-23)
  - The product ID string descriptor (Table 26-24)
  - The configuration string descriptor (Table 26-25)
  - The interface string descriptor (Table 26-26)

**Table 26-22. Language ID String Descriptor**

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

**Table 26-23. Manufacturer ID String Descriptor**

Field	Value	Description
bLength	0x06	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	TI	Manufacturer string

**Table 26-24. Product ID String Descriptor**

Field	Value	Description
bLength	0x0c	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	OMAP3430 or specific vendor string	Product string

**Table 26-25. Configuration String Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbcb	Configuration string

**Table 26-26. Interface String Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

### 26.4.5.3.2 USB Customized Descriptors

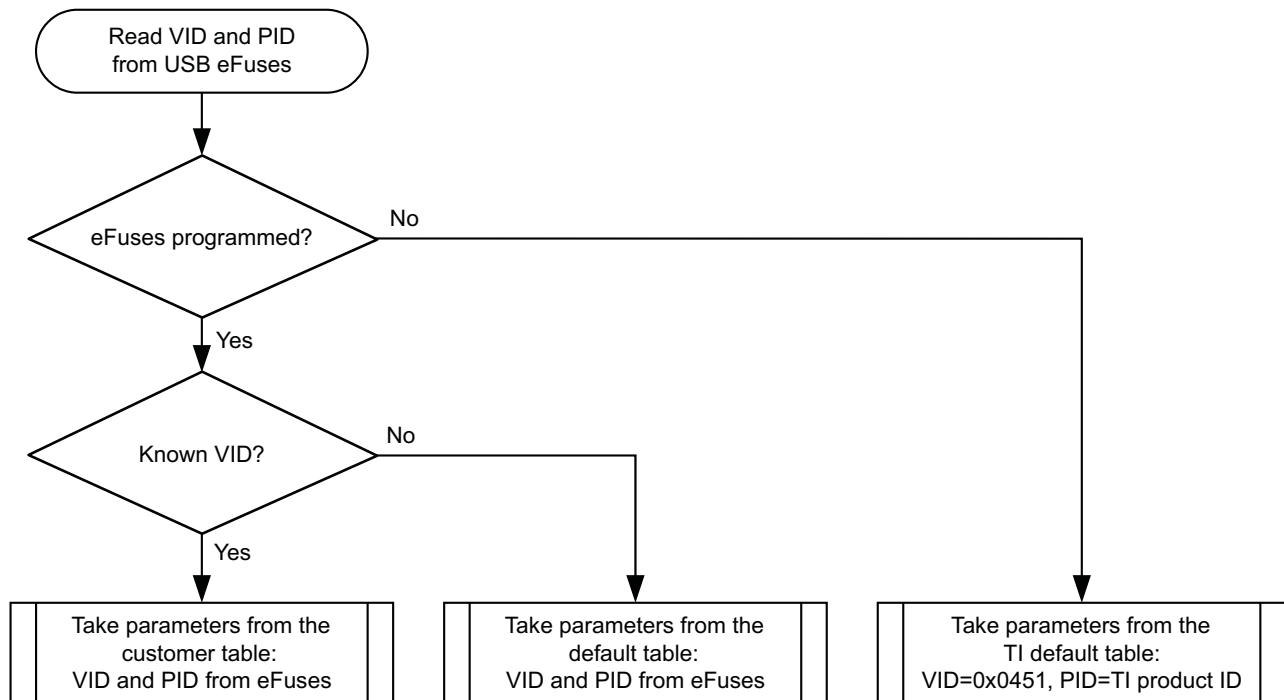

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. Table 26-27 lists the parameters that depend on VID value.

**Table 26-27. Customized Descriptor Parameters**

Parameter	Size [Bytes]	Default Values	TI Default Values
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	TI
Product	String	OMAP3430 or specific vendor string	OMAP3430 or specific vendor string
Serial number	String	N/A	N/A

Figure 26-12 describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

**Figure 26-12. Customer USB Descriptor Selection**

init-011

### 26.4.5.3.3 USB Driver Functionality

- Transactions supported

The following transactions are supported:

- Control transactions: Used for standard device requests
- Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.

- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. [Table 26-28](#) lists the standard device requests supported by the driver.

**Table 26-28. Standard Device Requests Supported**

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	No. Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	No. Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

## 26.4.6 Fast External Booting

### 26.4.6.1 Overview

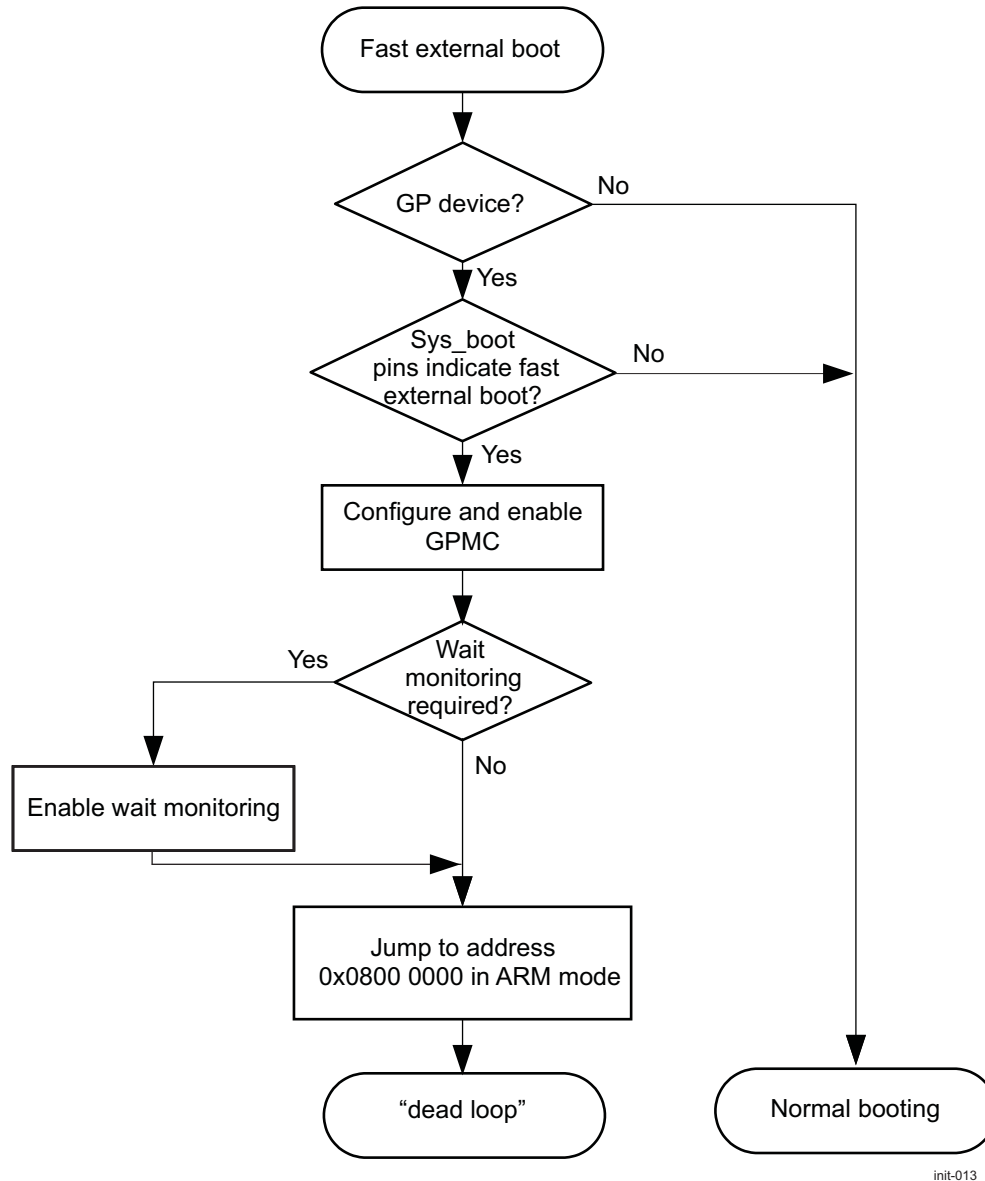

The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to chip-select 0 (CS0). Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

### 26.4.6.2 External Booting

Figure 26-13 shows the fast external boot procedure. The code is at the beginning and is written in assembly. The code does not use any RAM.

Figure 26-13. Fast External Boot Procedure

## 26.4.7 Memory Booting

### 26.4.7.1 Overview

The memory booting process starts an external code in memory type devices. Because the OMAP34xx device always uses these devices for booting, they are called permanent booting devices. The supported permanent booting devices are:

- All NOR devices up to 1 Gb (128M bytes)
- NAND devices from 64Mb
- OneNAND devices from 512Mb

- SD/MMC flash cards with active primary partition of type FAT12/16/32
- DiskOnChip H3 devices

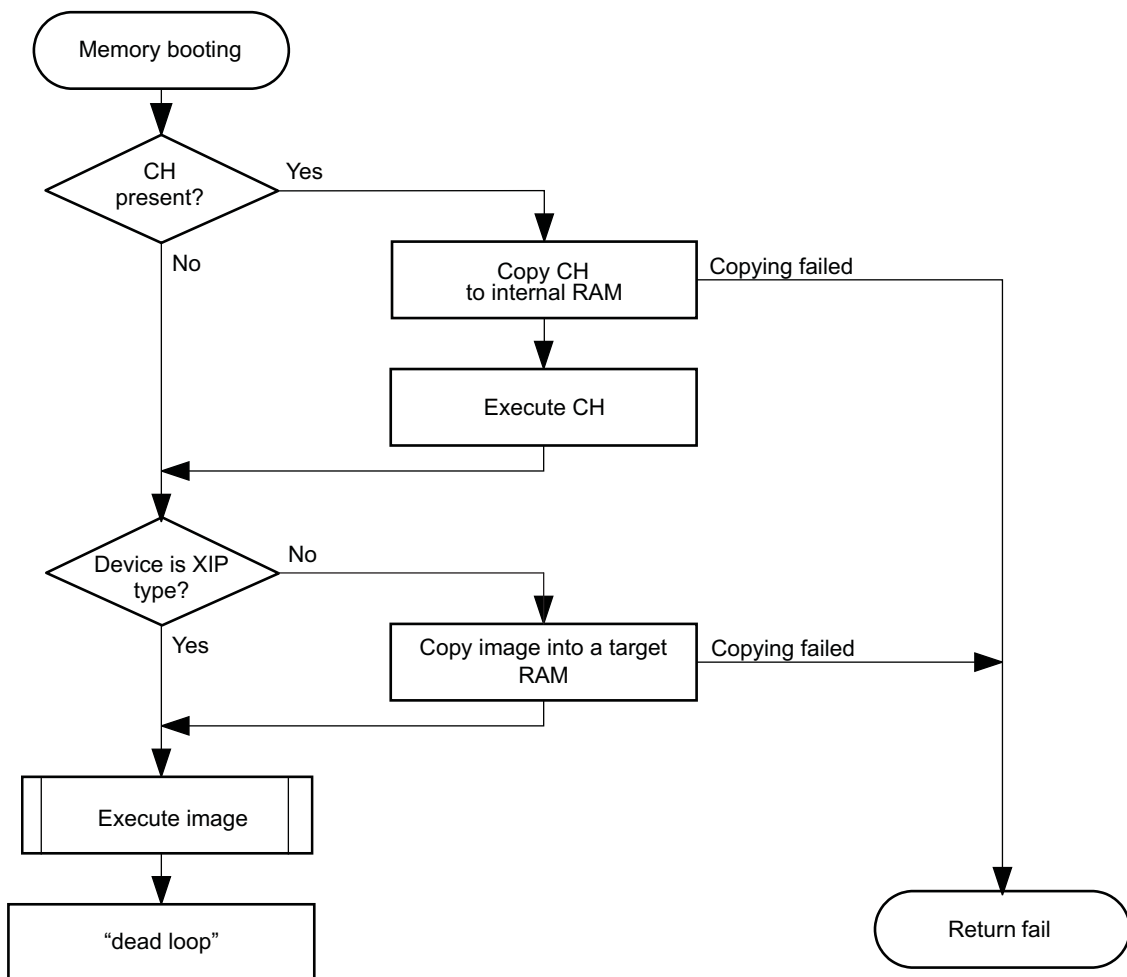

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

Figure 26-14 is the general memory booting procedure common to all types of devices. First, the CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP34xx device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image authentication and execution.

Unsuccessful authentication or return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

**Figure 26-14. Memory Booting Procedure**

init-014

### 26.4.7.2 Non-XIP Memory

Figure 26-15 shows the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

**Figure 26-15. Detailed Memory Booting for Non-XIP Devices**

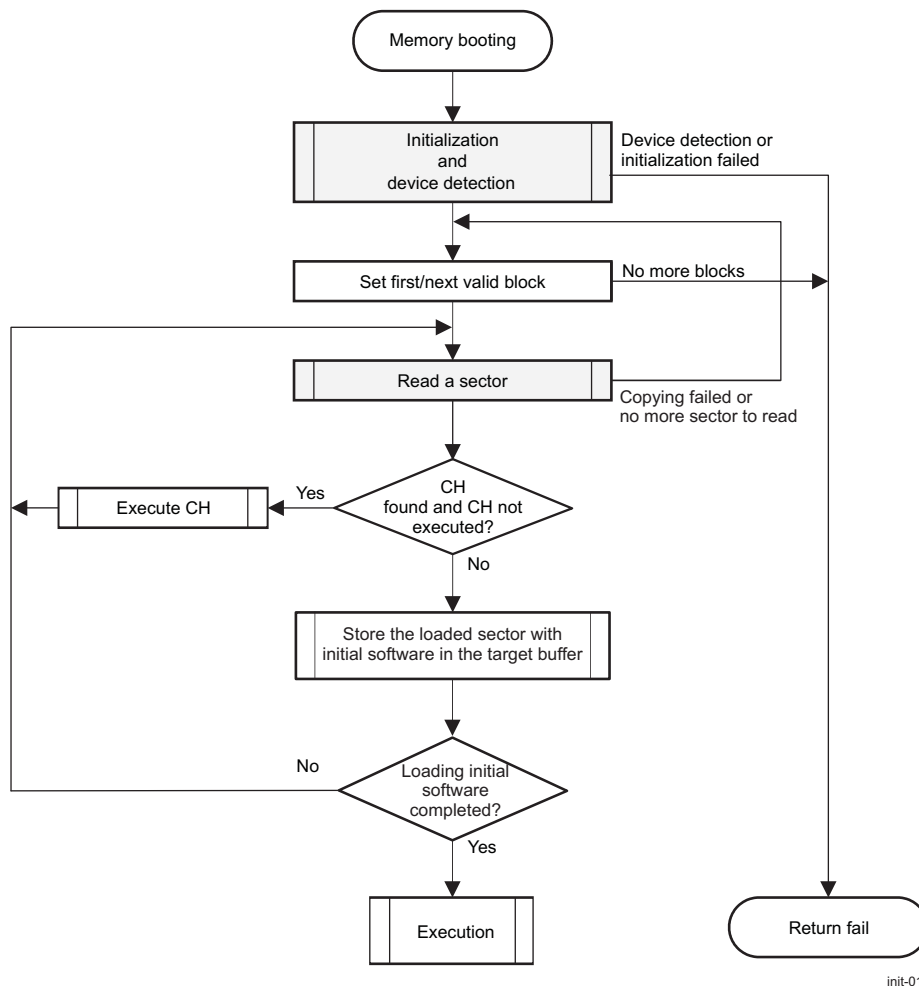

Table 26-29 summarizes numbers of blocks and sectors that are searched during memory booting from devices requiring image shadowing. NANDs and OneNAND are organized with blocks, which are erasable units. DOC memory reserves only one block for booting, which overlaps the XIP part. MMC/SD card booting consists of reading a file. Because there is only one file read, it can be considered one block trial.

**Table 26-29. Blocks and Sectors Searched on Non-XIP Memories**

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block <sup>(1)</sup>
OneNAND	First 4	8
DOC <sup>(2)</sup>	1	4
MMC/SD	One file	1

<sup>(1)</sup> Depends on NAND type

<sup>(2)</sup> Because XIP booting always precedes DOC booting and the same data is used for XIP areas, the DOC memory image must contain the first sector filled with 0xFF or 0x00. Therefore, a void sector at the beginning makes XIP booting fail and moves to DOC booting.

The following sections describe the supported device types.

For more information about the GPMC module, see [Chapter 11, Memory Subsystem](#).

### 26.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1GB (128MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc\_wait0 is monitored according to the sys\_boot configuration pins.

Depending on the sys\_boot option, the GPMC can be configured to use the wait signal connected to the gpmc\_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc\_wait0 is low. Wait monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device.

Bootting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 B) to internal RAM and execute the CH.
3. Set the image location:
  - 0x0800 0000 if the CH is not found
  - 0x0800 0200 if the CH (512 bits) is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

#### 26.4.7.3.1 GPMC Initialization

[Table 26-30](#) describes the timing settings of GPMC set for XIP and other address-data accessible devices, like DiskOnChip or OneNAND. [Table 26-30](#) is included for debug information.

**Table 26-30. XIP Timing Parameters**

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle time	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2

**Table 26-30. XIP Timing Parameters (continued)**

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x03
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

#### 26.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 64 Mb (8MB)
- x8 and x16 bus width
- Small page size (512 bytes + 16 bytes) and large page size (2048 bytes + 64 bytes)
- Chip enable (CE) don't care devices only
- Single level cell (SLC) and multilevel cell (MLC) devices
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc\_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

##### 26.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection/verification.

- GPMC initialization  
The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 26-31](#) shows the GPMC configuration used during NAND boot. [Table 26-31](#) is included for debug information.

**Table 26-31. NAND Timing Parameters**

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	20	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14.	0x11
Read cycle time	20	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14.	0x11

**Table 26-31. NAND Timing Parameters (continued)**

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
CS low time	0	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0.	0x1
OE low time	5	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x3
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	14	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE.	0xF

- Device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported device, the device parameters are extracted from an internal ROM code table. [Table 26-32](#) lists the supported devices.

**Table 26-32. Supported NAND Devices**

Capacity	Device ID	Bus Width	Page Size in KB
64Mb	E6h	8	512
128Mb	33h	8	512
128Mb	73h	8	512
128Mb	43h	16	512

1Gb	A1h	8	2048
1Gb	F1h	8	2048
1Gb	B1h	16	2048
1Gb	C1h	16	2048

**Table 26-32. Supported NAND Devices (continued)**

Capacity	Device ID	Bus Width	Page Size in KB
2Gb	AAh	8	2048
2Gb	DAh	8	2048
2Gb	BAh	16	2048
2Gb	CAh	16	2048
2Gb	71h	8	512
2Gb	51h	16	512
2Gb	31h	8	512
2Gb	41h	16	512
4Gb	ACh	8	2048
4Gb	DCh	8	2048
4Gb	BCh	16	2048
4Gb	CCh	16	2048
8Gb	A3h	8	2048
8Gb	D3h	8	2048
8Gb	B3h	16	2048
8Gb	C3h	16	2048
16Gb	A5h	8	2048
16Gb	D5h	8	2048
16Gb	B5h	16	2048
16Gb	C5h	16	2048
32Gb	A7h	8	2048
32Gb	B7h	16	2048
64Gb	A Eh	8	2048
64Gb	B Eh	16	2048

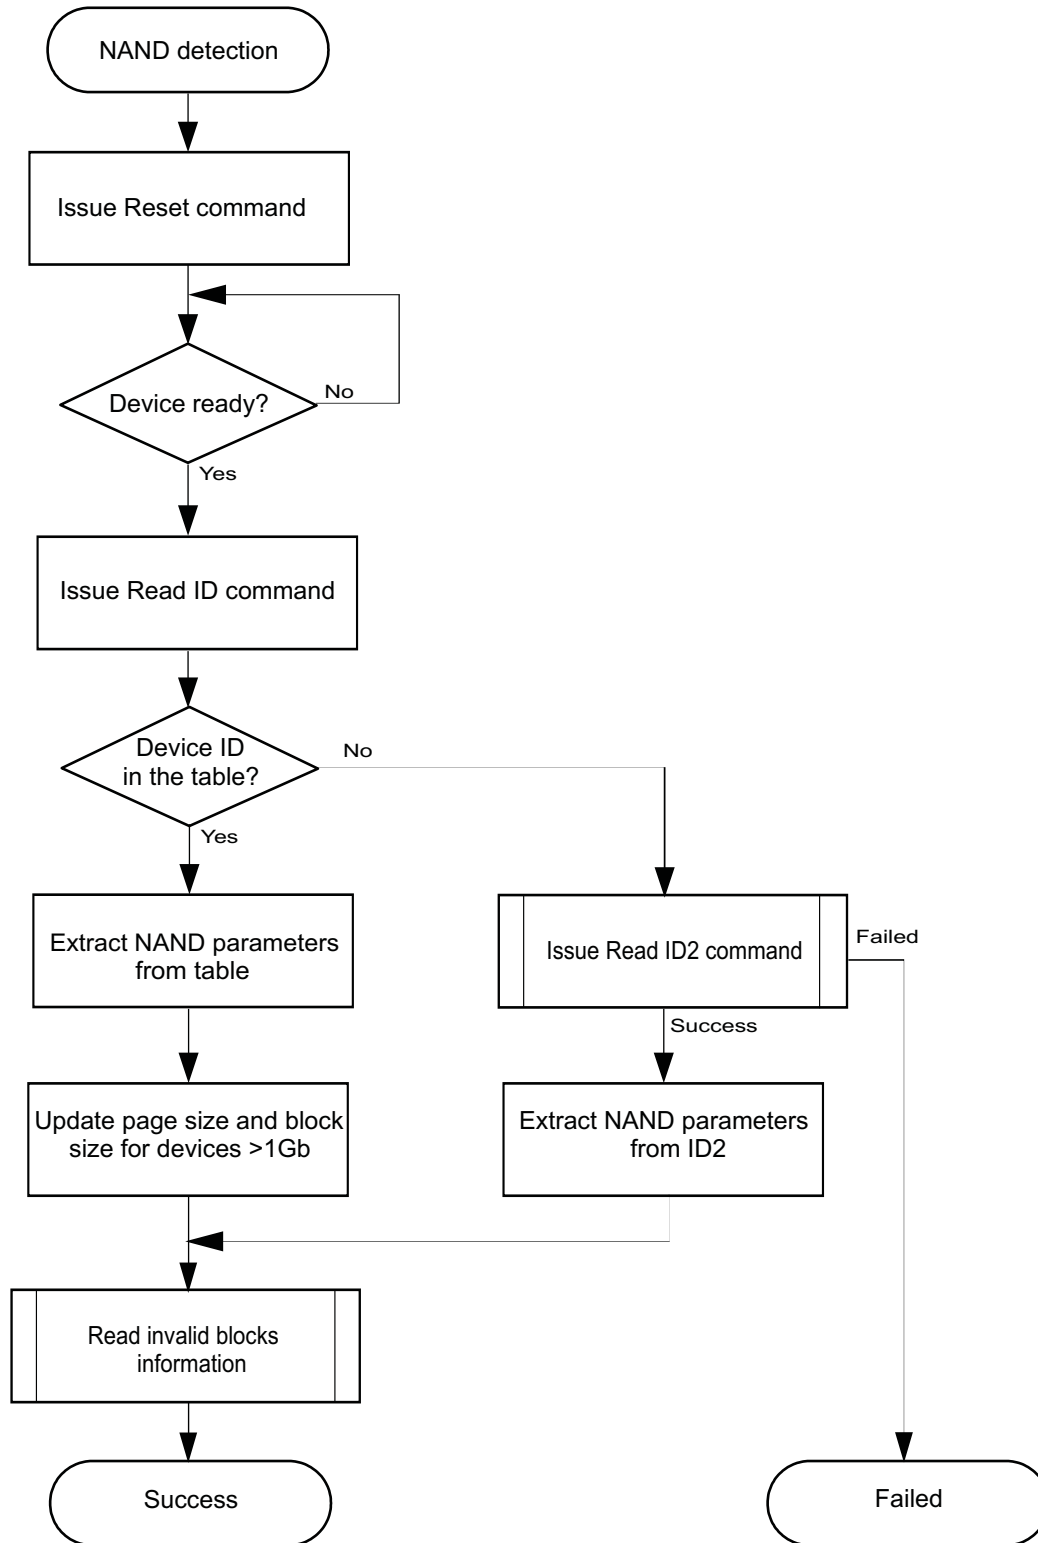

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512KB and to 128KB when the page size is 2048KB. [Table 26-33](#) shows the fourth ID data byte encoding used in the ROM code.

**Table 26-33. Fourth NAND ID Data Byte**

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
<b>Page Size</b>	1KB							0	0
	2KB							0	1
	4KB							1	0
	8KB							1	1
<b>Block Size</b>	64KB			0	0				
	128KB			0	1				
	256KB			1	0				
	512KB			1	1				

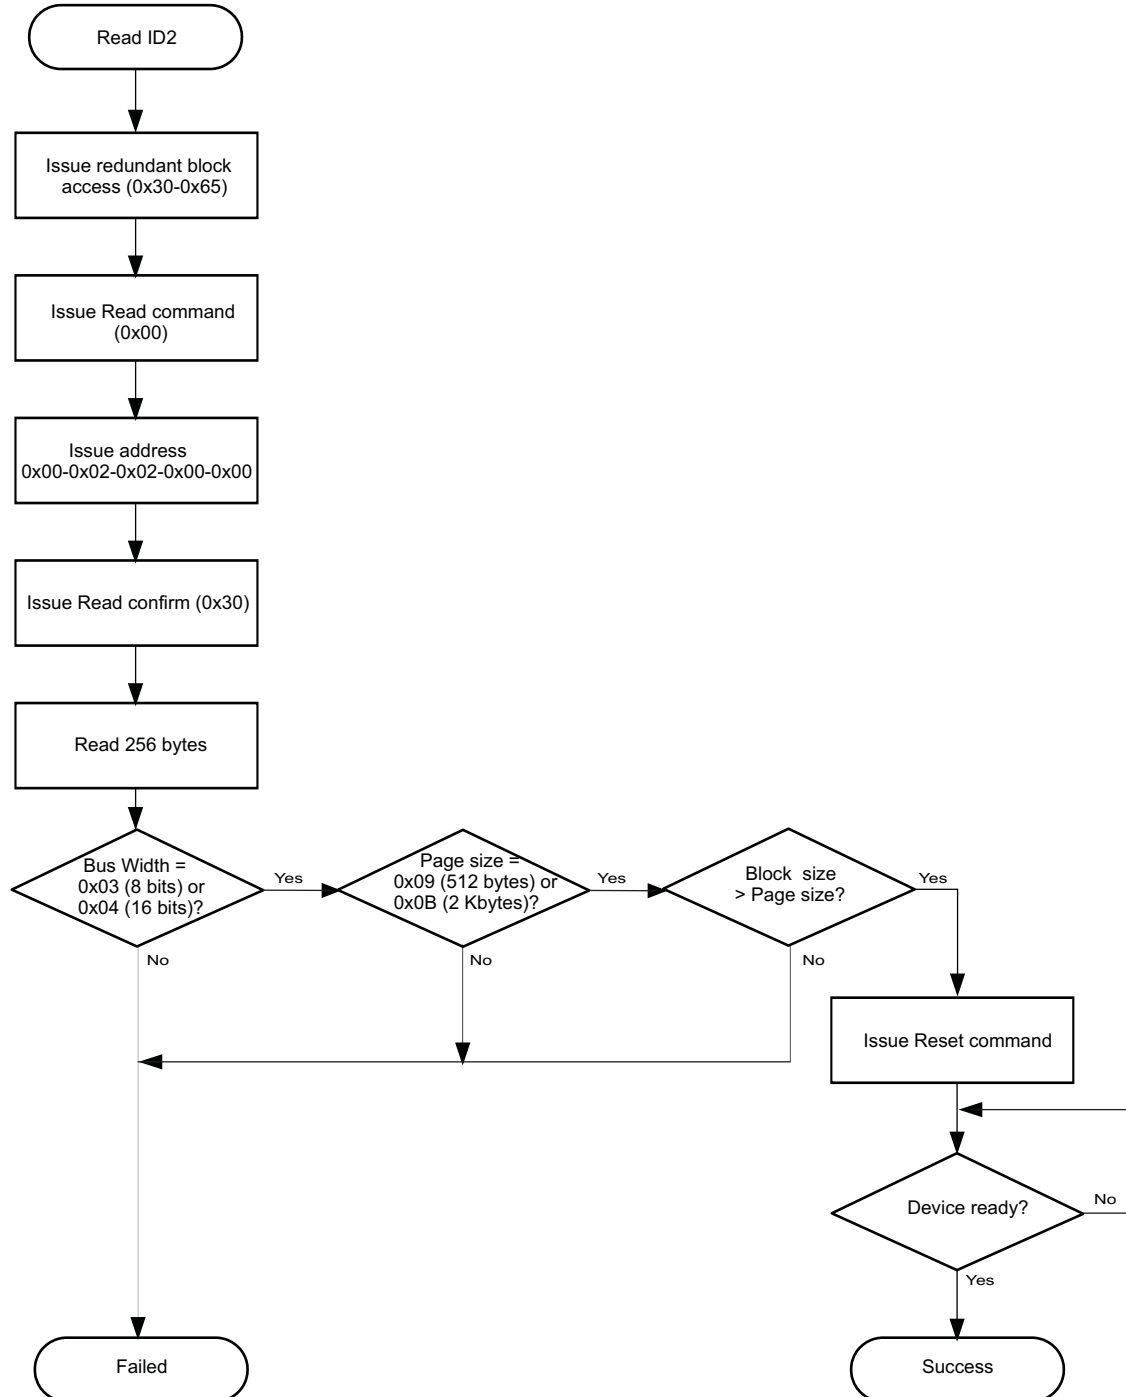

The detection procedure is described in [Figure 26-16](#). If the device ID is not recognized, the ROM code tries to read ID2 from the device; the sequence is described in [Figure 26-17](#). The description of the ID2 data content is summarized in [Table 26-34](#). If the ROM code fails to identify device ID or ID2, it returns with FAIL. When the device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

- **Bad block detection/verification**

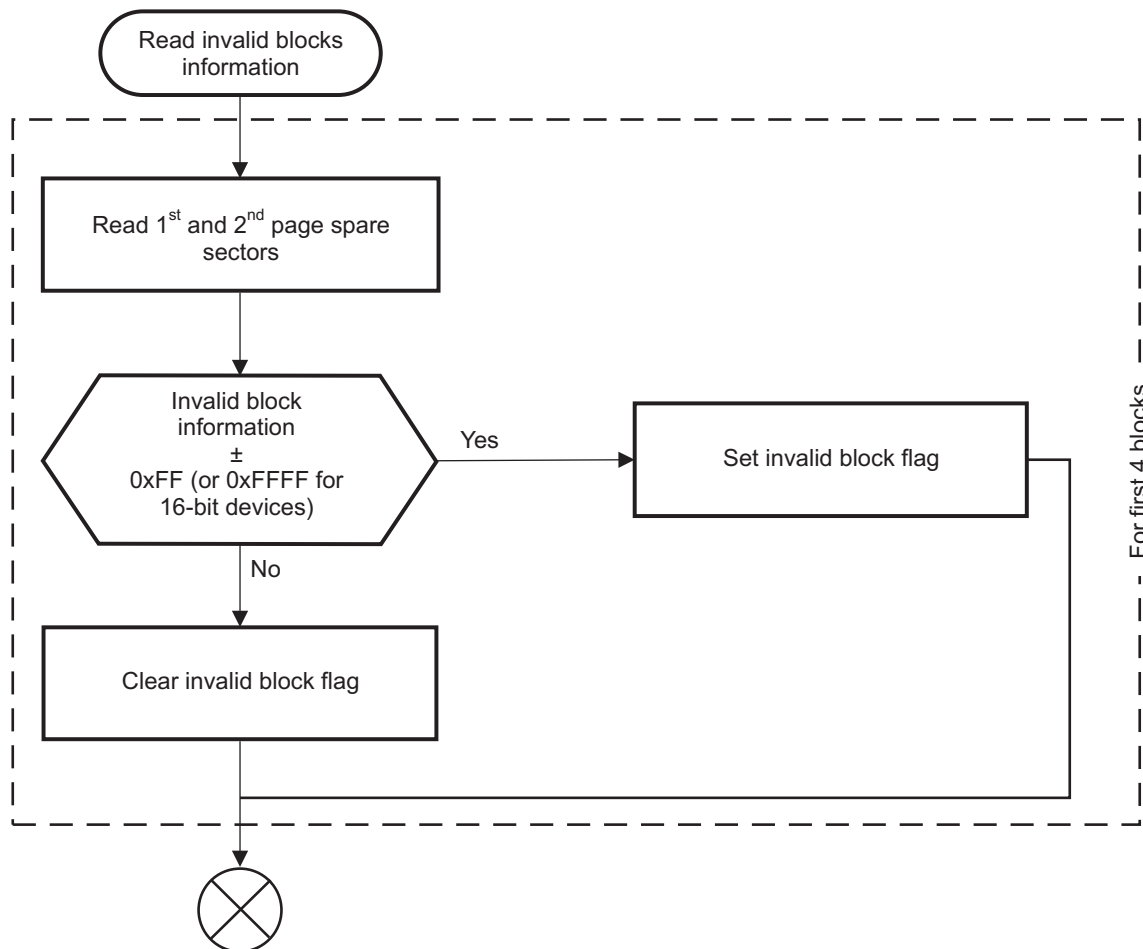

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block. [Table 26-35](#) lists the validity status coding for the four NAND families.

**Table 26-35. Bad Block Mark Locations in NAND Spare Areas**

	Small Page NAND	Large Page NAND
8-bit device Block invalid when any byte does not equal FFh	6th byte in 1st page	1st byte in 1st page
	6th byte in 2nd page	1st byte in 2nd page
16-bit device Block invalid when any word does not equal FFFFh	1st word in 1st page	1st word in 1st page
	6th word in 1st page	1st word in 2nd page
	1st word in 2nd page	
	6th word in 2nd page	

Figure 26-18 shows the invalid block detection routine. The routine consists in reading spare areas and checking data according to the conditions listed in Table 26-35. The flags are used internally to give information about the validity of each block.

**Figure 26-18. Bad NAND Invalid Block Detection**

init-033

**26.4.7.4.2 Read Sector Procedure**

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.

- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration. To correct these errors, the ROM code uses ECC, based on Hamming codes for SLC NAND and BCH (Bose, Ray-Chaudhuri, Hocquenghem) code for multilevel cell (MLC) devices. The computed ECC is compared to ECC stored in the spare area of the corresponding page. If there are uncorrectable errors, the ROM code returns with FAIL.

#### **26.4.7.5 OneNAND**

ROM code support for OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc\_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.

The OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

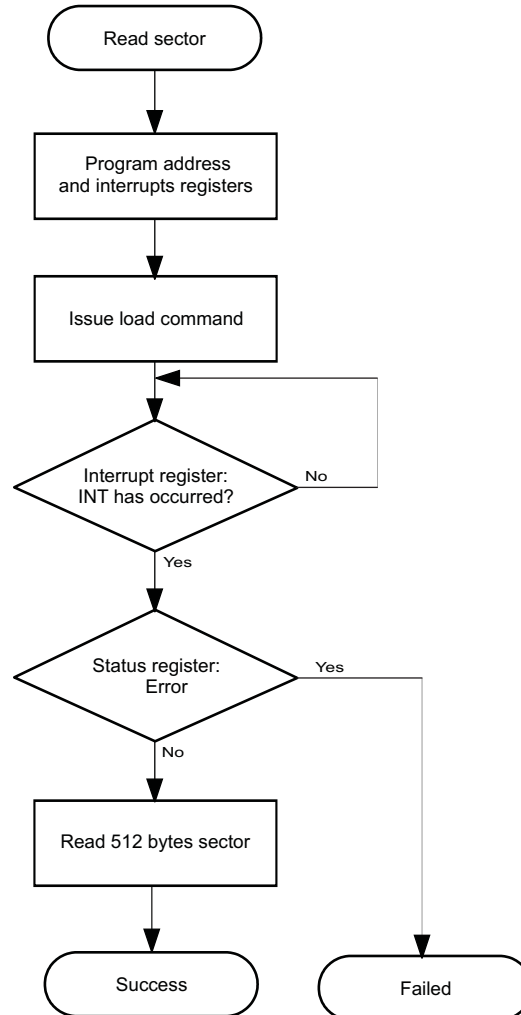

##### **26.4.7.5.1 Initialization and OneNAND Detection**

The initialization routine for OneNAND consists of two parts: GPMC initialization and device detection with parameter determination:

- GPMC initialization  
The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See [Table 26-30](#).
- Device detection and parameters  
The ROM code identifies a OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

##### **26.4.7.5.2 OneNAND Read Sector Procedure**

When booting requests a sector from the OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 26-19](#) shows this procedure.

**Figure 26-19. OneNAND Read Sector**

init-025

#### 26.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v2.0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 3-V power supply, 3-V I/O and 1.8-V I/O voltages on POR 1
- Supports eMMC/eSD (1.8-V I/O voltage and 3.0-V Core voltage) on port 2. The external transceiver mode on port 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: 20 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).
- For a FAT (12/16/32)-formatted memory card, the booting file must not exceed 128 KB.

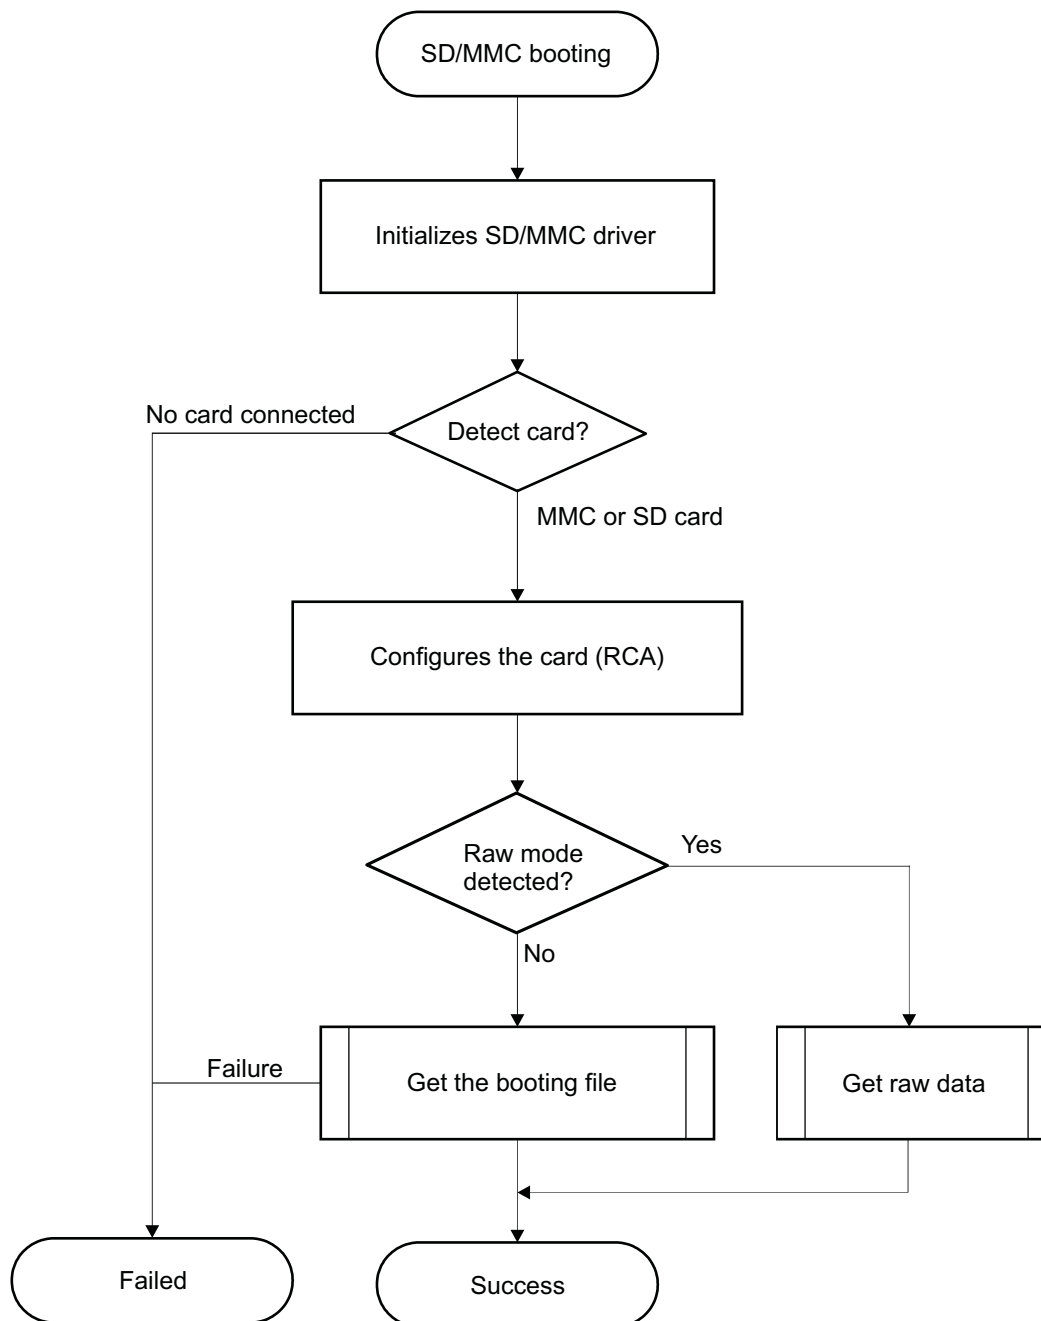

- For a raw-mode memory card, the booting image must not exceed 128 KB.

For MMC memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only standard operating voltage range (3 V) (both modes supported).

The ROM code reads a booting file from the card file system and boots from it. [Figure 26-20](#) shows the complete procedure.

**Figure 26-20. MMC/SD Booting**

init-016

### 26.4.7.6.1 Connectivity Constraints

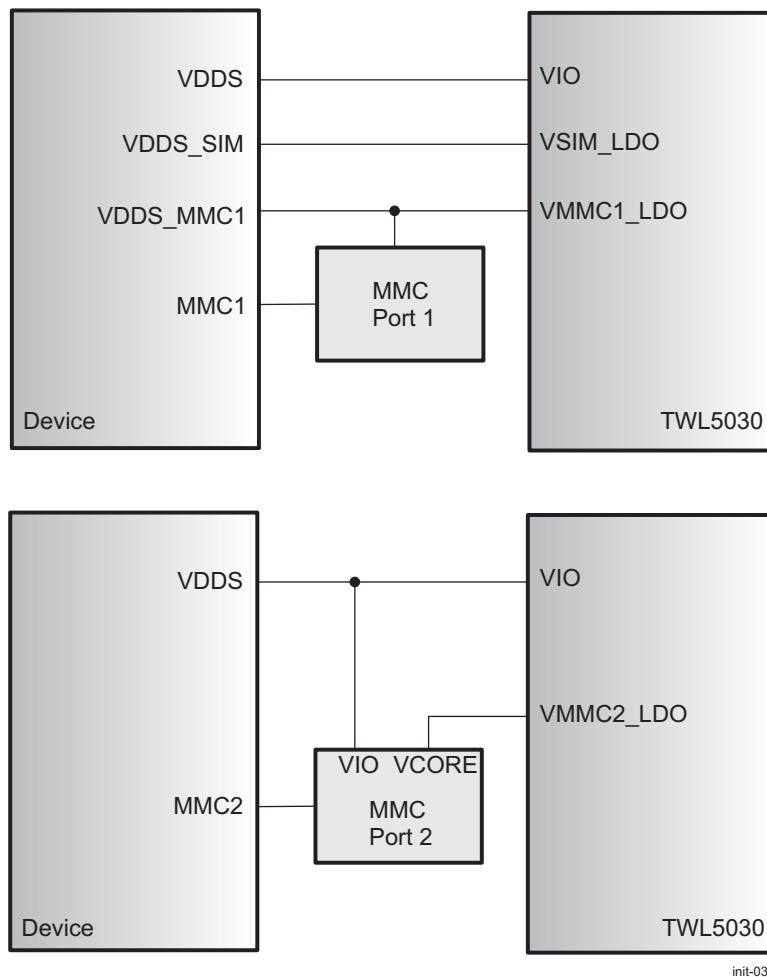

MMC port 1 can support I/O in two modes, 1.8 V or 3.0 V, provided the correct voltage supply is connected to the VDDS\_MMC1 pin. Hardware provides the mechanism to detect the presence of 3.0 V on VDDS\_MMC1. If the hardware does not detect 3.0 V, the ROM code assumes 1.8-V voltage is present and configures the I/O pads accordingly.

To enable the hardware to generate the correct levels on the MMC interface, the following connectivity constraints must be respected.

#### 26.4.7.6.1.1 Booting From MMC/SD Memory in Case TWL5030 is Implemented

Before performing a memory access, the ROM code tries to detect the presence of a TWL5030 power management device on the I2C bus. If one is detected, the ROM code assumes the connections shown in [Figure 26-21](#) are present.

**Figure 26-21. TWL5030 Connectivity Constraints to Support MMC/SD/eMMC/eSD Booting on MMC Port 1 and MMC Port 2**

The ROM code configures the TWL5030 through I2C to set the following:

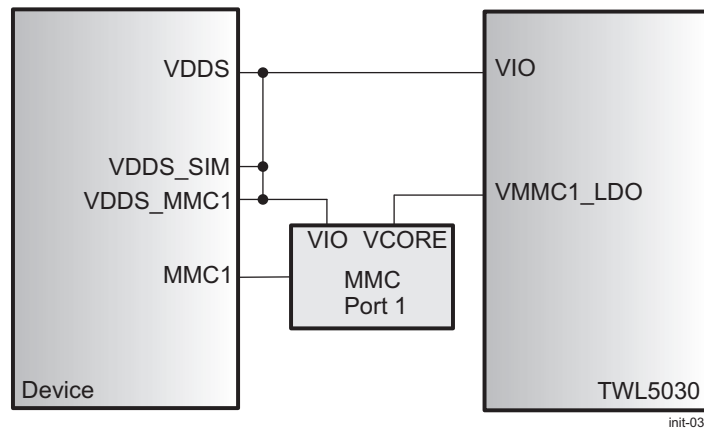

- VMMC1\_LDO is set to 3.0 V when booting from MMC port 1 is requested from the sys-boot pins.
- VSIM\_LDO is set to 3.0 V only when a configuration header configuring an 8-bit bus is embedded in the booting image. If an 8-bit bus is not required at boot time, it is not mandatory to connect VSIM\_LDO to VDDS\_SIM.
- VMMC2\_LDO is set to 3.0 V when a booting from MMC port 2 is requested from the sys-boot pins. Users must furnish VIO = 1.8 V to the MMC memory, respecting the timing sequence imposed by the memory.

### 26.4.7.6.1.2 Booting From eMMC/eSD Memory From MMC Port 1 When TWL5030 is Implemented

ROM code can boot from the embedded multimedia card/embedded SD card (eMMC/eSD) on port 1. Most of these memories require two power supplies. One power supply is required for the I/O interface (CMD, CLK, DAT[7:0]), and the other is required for the memory core. The VIO voltage is typically 1.8 V, and the VCORE voltage is 3.0 V.

For eMMC/eSD booting with two power supplies, the implementation shown in Figure 26-22 is required.

Figure 26-22. TWL5030 Connectivity Constraints to Support MMC/SD/eMMC/eSD Booting on MMC Port 1

### 26.4.7.6.1.3 Booting When TWL5030 is Not Implemented

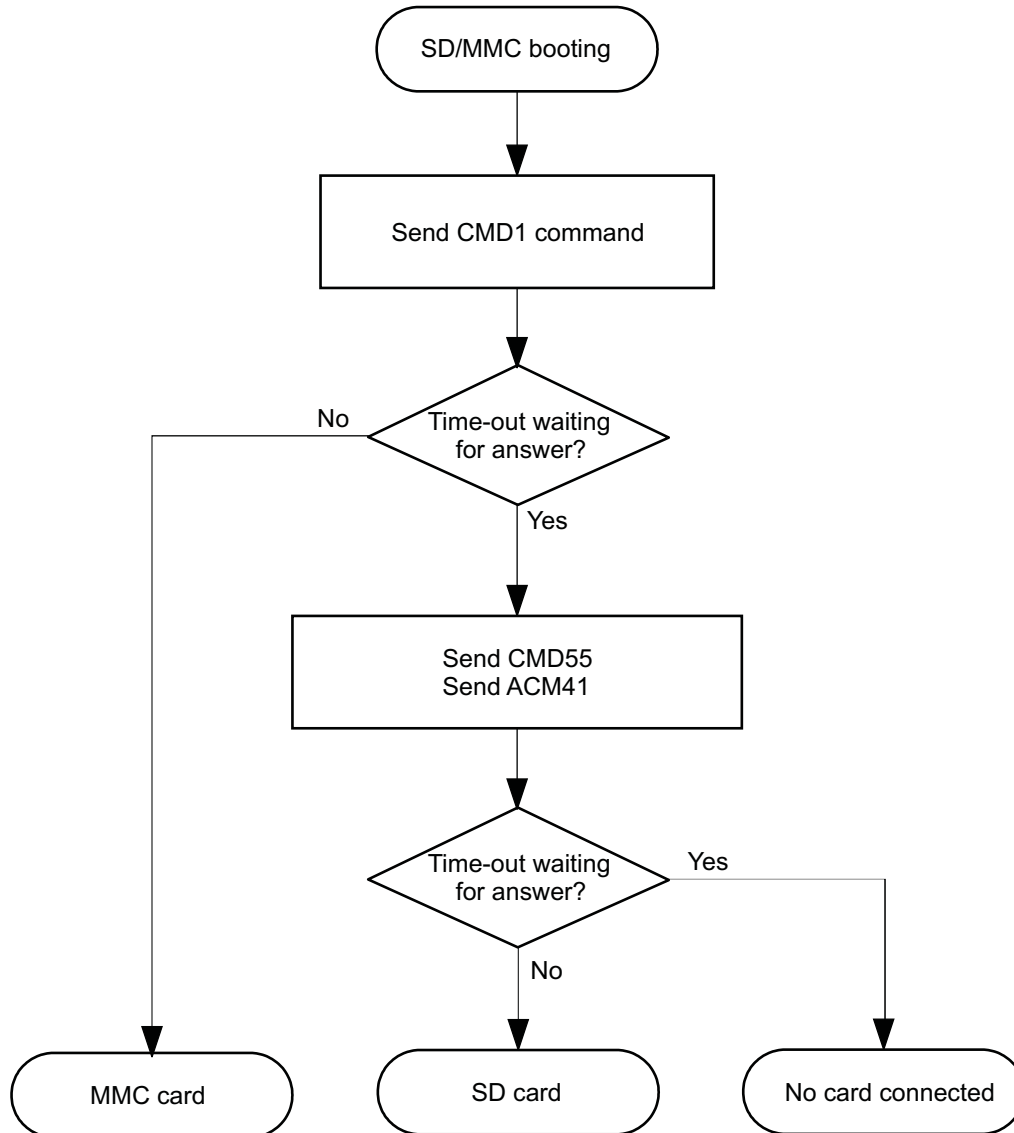

When TWL5030 is not implemented, the ROM code assumes the following:

- The MMC/SD card memory connected to MMC port 1 is powered by a 3.0-V power supply after any POR or software or warm reset.
- The VDDDS\_MMC1 pin of the device is connected to a 3.0-V power supply that is the same as the one that powers the MMC/SD memory on MMC port 1.
- The VDDDS\_VSIM pin of the device is connected to a power supply that is the same as the one that powers the MMC/SD memory, when a configuration header setting the bus width to 8 bits is implemented in the booting image.
- The eMMC/eSD memory connected to MMC port 2 has its VIO power domain connected to a 1.8-V power supply after any POR or software or warm reset.
- The eMMC/eSD memory connected to MMC port 2 has its VCORE power domain connected to a 3.0-V power supply after any POR or software or warm reset.

### 26.4.7.6.2 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the standard high-voltage range (3.0 V) if a card is plugged in. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands, CMD1 and ACMD41. The ROM code uses this command difference to differentiate between MMC and SD cards; that is, CMD1 is supported only by MMC and ACMD41 is supported only by SD. The ROM code first sends a CMD1 to the card and gets an answer only if an MMC card is connected. If no answer is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an answer is expected from an SD card. If no answer is received, no cards are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 26-23 shows the MMC/SD detection procedure.

**Figure 26-23. MMC/SD Detection Procedure**

init-026

**26.4.7.6.3 Read Sector Procedure**

- Raw mode

In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0. If a CH is in this first sector, raw mode is validated. The CH can be void, as described in [Section 26.4.8.2, CH](#). To summarize, ROM code decides to switch to raw mode if the first read sector contains a TOC structure with an MLO or CHSETTINGS item. If raw mode is not detected, file system mode is assumed. Image data is read directly from continuous sectors of a card.

- File system handling

The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

#### 26.4.7.6.4 File System Handling

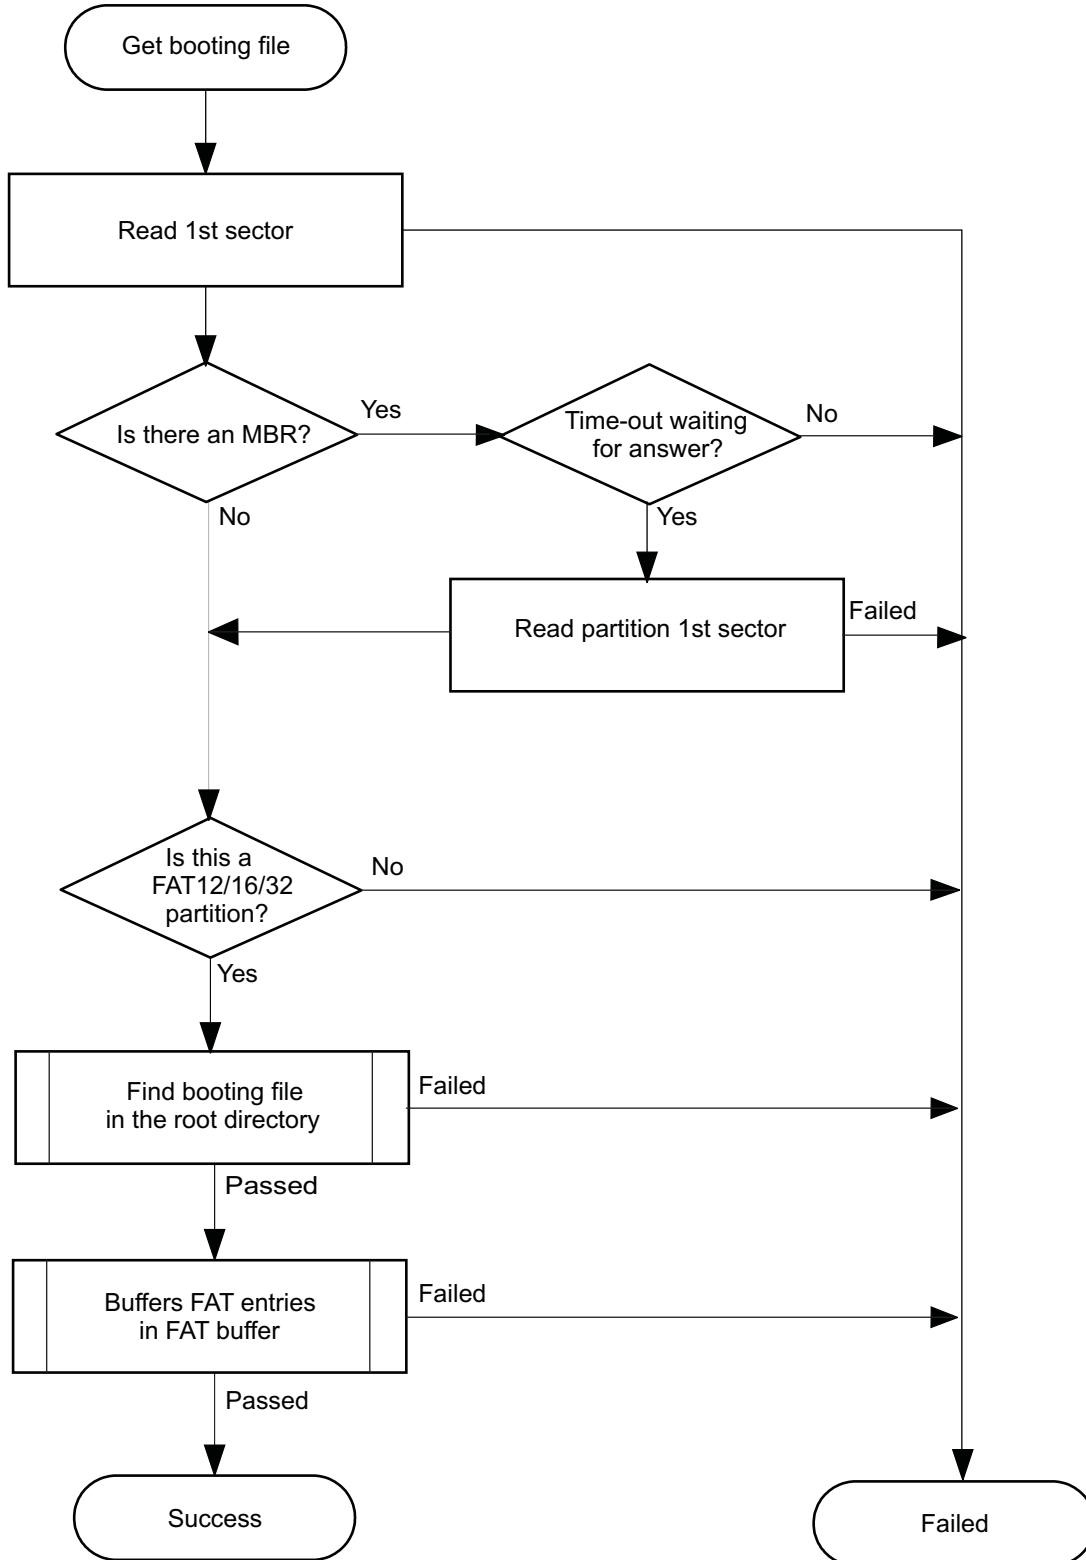

The MMC/SD cards can hold a file system that ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card should always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 26-24](#) shows the complete process.

Figure 26-24. SD/MMC Booting

init-027

### 26.4.7.6.4.1 MBR and FAT File System

This paragraph describes functionalities used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 26-36](#); partition table entry is described in [Table 26-37](#).

**Table 26-36. Master Boot Record Structure**

Offset	Length [Bytes]	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (= 0xAA55)

**Table 26-37. Partition Table Entry**

Offset	Length [Bytes]	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S+ Hs.S+ Ss–1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S+ He.S+ Se–1 Nb s= LBAe–LBAs + 1

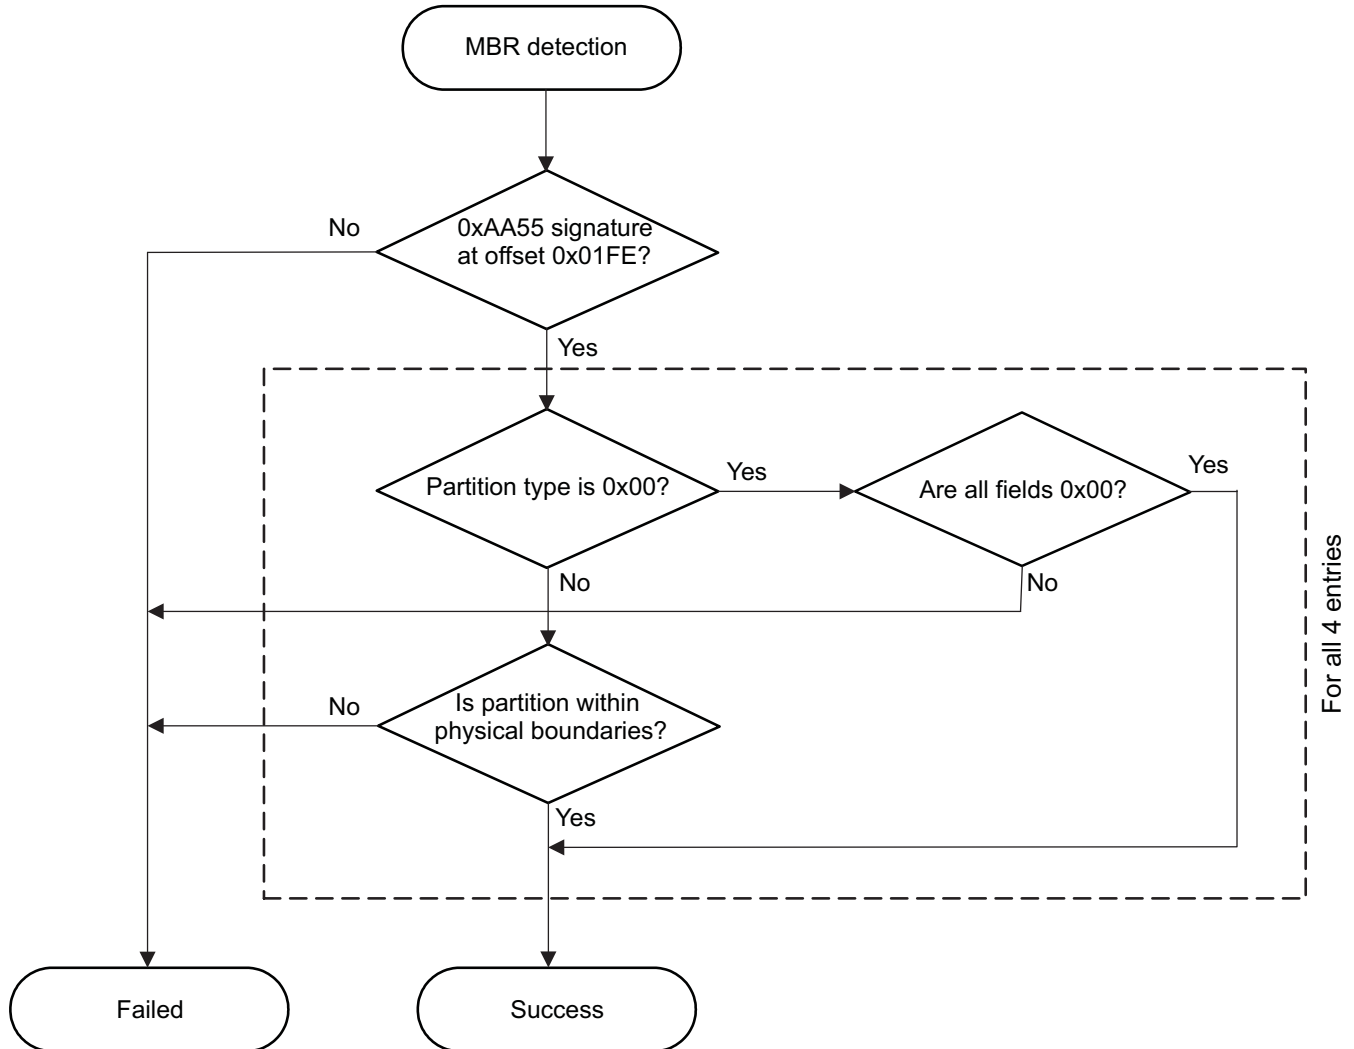

SD/MMC booting consists of the following steps:

Step 1. MBR detection

The ROM code first checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- a. If its type is set to 00h, all fields in the entry must be 00h.
- b. The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 26-25](#) for more information about MBR detection.

**Figure 26-25. MBR Detection Procedure**

init-028

**Step 2. Get the MBR partition.**

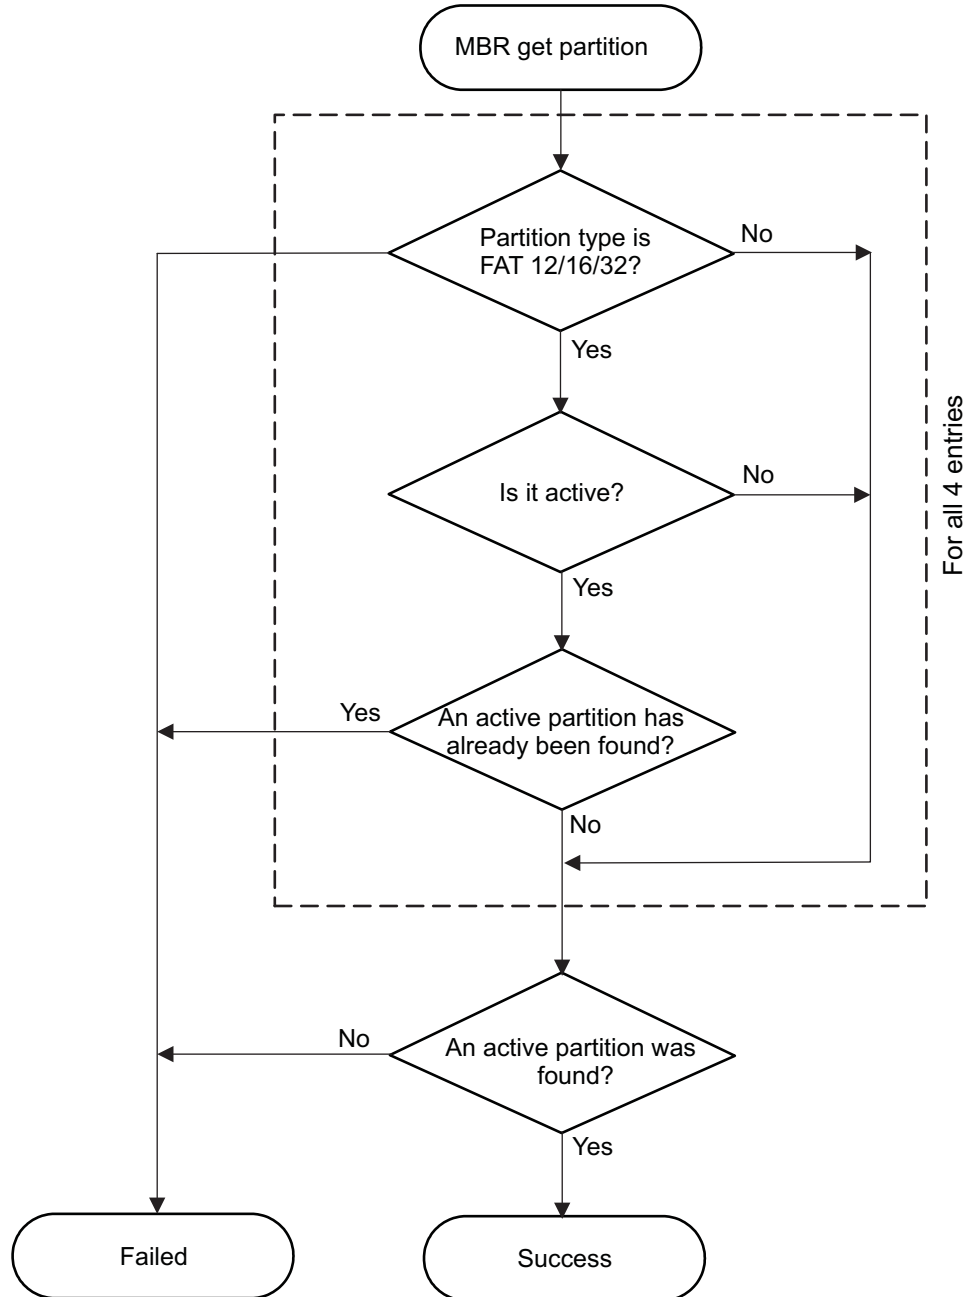

Once identified, the ROM code gets the partition using the procedure described in [Figure 26-25](#). The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux® FS) or if the partition is not valid, the ROM code returns with FAIL.

The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location).

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. [Figure 26-26](#) shows more information about getting the MBR partition.

Figure 26-26. Get MBR Partition

init-029

Step 3. Find the booting file.

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB\_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_NumFATs \cdot BPB\_FATSz + Cluster \cdot BPB\_SecPerCLus$$

init-E001

**Note:** BPB\_FatSz is BPB\_FatSz16 for FAT12/16 or BPB\_FatSz32 for FAT32.

**Note:** The BPB\_HiddSec field can contain 0 even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 26-38](#).)

**Table 26-38. FAT Directory Entry**

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_LONG_NAME ATTR_READ_ONLY   ATTR_HIDDEN ATTR_SYSTEM   ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR\_LONG\_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR\_FstClusHi/DIR\_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB\_RootEntCnt, which is the total of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in the following paragraph.

Step 4. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB\_FATsSz16 or BPB\_FATsSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB\_ExtFlags[7]. If this flag is set, the FAT BPB\_ExtFlags[3:0] bit field is used. In this case no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 26-39](#).

**Note:** For compatibility, cluster 0 and cluster 1 are not used for files, and those entries must contain FF8h and FFFh (for FAT12), FFF8h and FFFFh (for FAT16), and ?FFFFFFF8h and ?FFFFFFFh (for FAT32).

**Table 26-39. FAT Entry Description**

FAT12	FAT16	FAT32	Description
000h	0000h	?0000000h	Free cluster
001h	0001h	?0000001h	Reserved cluster
002h-FEFh	0002h- FFEFh	00000002h- ?FFFFFFEFh	Used cluster; value points to next cluster
FF0h-FF6h	FFF0h- FFF6h	?FFFFFFF0h- ?FFFFFFF6h	Reserved values
FF7h	FFF7h	?FFFFFFF7h	Bad cluster
FF8h-FFFh	FFF8h- FFFh	?FFFFFFF8h- ?FFFFFFFh	Last cluster in file

**Note:** FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB\_SecPerClus). This buffer is used later by the booting procedure to access the file.

### 26.4.7.7 DiskOnChip

The ROM code support for DiskOnChip devices has the following characteristics:

- DiskOnChip H3
- 1.8-V power supply
- Density from 256 Mb

The DiskOnChip contains an XIP part that can hold a boot image. In this case, the DiskOnChip is connected just like a regular NOR device, and uses the same procedure as for NOR, described in [Section 26.4.7.3, XIP Memory](#).

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

## 26.4.8 Image Format

### 26.4.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

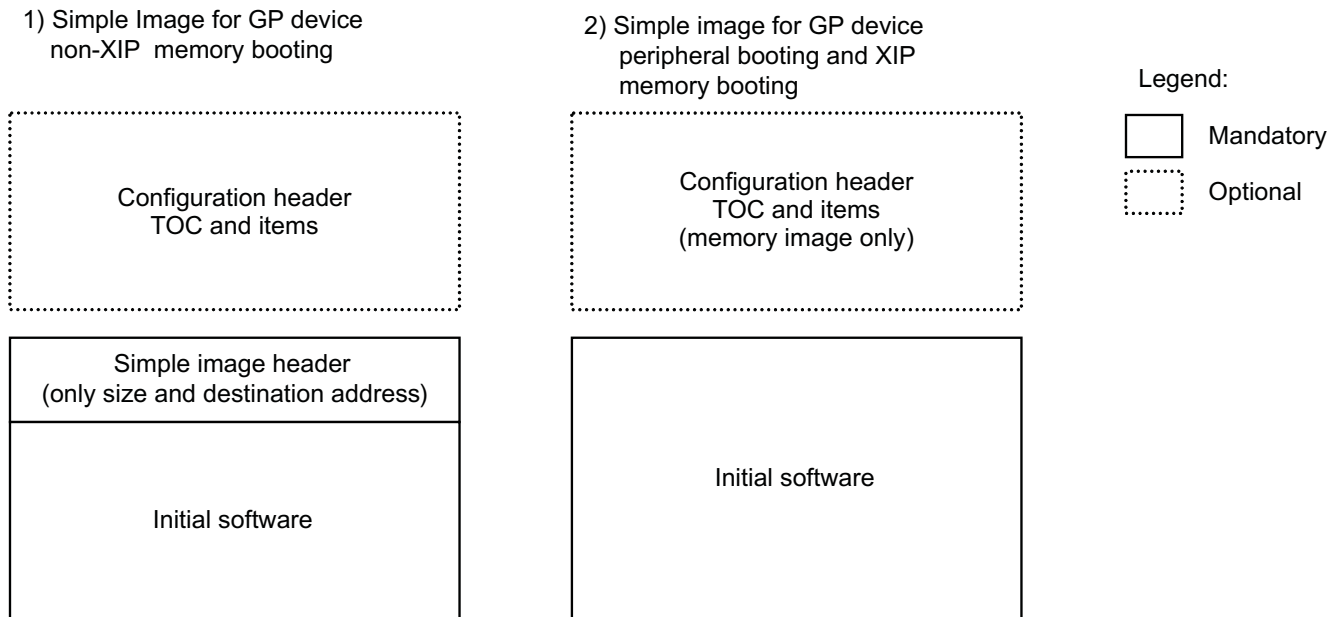

The CH, which is optional, can contain several parameters set by users to speed up booting. It is further described in the next section.

The mandatory part contains the software that is loaded into the memory and executed.

An overview of the image formats is shown in [Figure 26-27](#). There are two image types:

- GP non-XIP memory booting: This image type is used for memories that require shadowing. The image must begin with a simple header that contains information about the size to copy and the destination. This format is described in [Section 26.4.8.3, Image Format for GP Devices](#).
- GP XIP memory booting and peripheral booting: A GP image on XIP memory contains only code. The first sector can contain CH. The GP peripheral booting image contains only code.

**Figure 26-27. Image Format**

init-018

### 26.4.8.2 CH

The CH is optional and is required only if the customer wants to use settings different from the ROM code defaults (for example, clock frequencies, SDRAM/double-data rate [DDR] SDRAM settings, GPMC settings). The CH can be present only when booting from a memory-type device (for example, CH is not supported when booting from UART or USB). Therefore, the CH contains only settings for memory booting.

The CH can contain up to four parts:

- Settings: Clock settings (mandatory)
- RAM: SDRAM/DDR SDRAM interface settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMC/SDIO interface settings

The beginning of the CH is a table of contents (TOC) pointing to each item. This is described in [Figure 26-28](#). Each TOC item is a simple structure described in [Table 26-40](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Then, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

Figure 26-28. CH Format

init-019

Table 26-40. CH TOC Item

Offset	Field	Size [Bytes]	Description
0x0000	Start	4	Offset from the start address of TOC to the actual address of a section
0x0004	Size	4	Size of a section
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a section, including the zero (\0) terminator

### 26.4.8.2.1 CHSETTINGS

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in [Section 26.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clocking settings.

The fields are described in [Table 26-41](#). The clocking procedure, as well as the clocking setting structure are described in [Section 26.4.4.4, Software Booting Configuration](#).

The peripherals used during booting, that is, UART, MMC, and SSI are fed with 96 MHz and 48 MHz. This cannot be changed in the configuration header as it is only available for memory booting.

**Table 26-41. CHSETTINGS**

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C1h
0004h	Valid	Enables/disables the section 00h – Disable Other – Enable
0005h	Version	Configuration header version 0001h Others – For future use
0006h	Reserved	
0008h	Clocking settings	Described in <a href="#">Table 26-12</a> , <i>Software Booting Configuration Structure</i> , starting from the FLAGS field.

**26.4.8.2.2 CHRAM**

The CHRAM configuration header contains settings specific to SDRAM memory controller (SDRC). The fields are described in [Table 26-42](#). The ROM code does not configure the SDRC by default, as it cannot assume any external SDR/DDR SDRAM type. Refer to the SDRC section of Chapter 11 for more information.

**Table 26-42. CHRAM**

Offset	Field	Description CH – used in CH process CR – used in context restore	
0000h	Section key	Key used for section verification: C0C0C0C2h.

		[0]:	0= CS0 not configured 1= CS0 configured
		[1]:	0= CS1 not configured 1= CS1 configured
005A	Must be 0	CH	CR

### 26.4.8.2.3 CHFLASH

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). Refer to the *GPMC* section of [Chapter 11, Memory Subsystem](#), for more information. The fields are described in [Table 26-43](#). The ROM code configures the GPMC by default to these settings:

- Chip select 0
- Asynchronous mode
- Wait input enabled
- Base address 08000000h

**Table 26-43. CHFLASH**

Offset	Field	Description
0000h	Section Key	Key used for section verification: C0C0C0C3h.
0004h	Valid	Enables/disables the section: 00h – Disable Others – Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register value
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Enable_A1_A10	0 – Do not change A1 – A10 Others - Enable pins A1 – A10

#### 26.4.8.2.4 CHMMCS D

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). Refer to [Chapter 22, MMC/SD/SDIO Card Interface](#), for more information. The fields are described in [Table 26-44](#). The ROM code configures the MMCHS by default to these settings:

- 400-kHz clock during identification mode
- 19.2-MHz clock during data transfer mode

**Table 26-44. CHMMCS D CH**

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section 00h – Disable Other – Enable
0005h	Reserved	
0008h	MMCHS_SYSCCTRL(MSB)	Register value
000Ah	MMCHS_SYSCCTRL(LSB)	0xFFFFFFFF -> Do not update register. 1 -> 1 bit
000Ch	Bus width	2 -> 4 bits 4 -> 8 bits 0xFFFFFFFF -> Do not update register.

---

**Note:** The ROM code transmits a booting parameters structure to the initial software (see [Section 26.4.8.4, Image Execution](#)). This structure contains a field indicating whether the configuration header sections have been correctly taken into account. For the CHMMCSO section, if all the section fields are set to 0xFFFFFFFF, regardless of the value of the VALID bit field, the booting parameters should indicate that the CHMMCSO section has not been executed.

---

### 26.4.8.3 Image Format for GP Devices

For a GP device, the image is simple and must contain a small header having the size of the software to load and the destination address of where to store it when a device is other than XIP. The XIP device image is even simpler and starts with executable code. The image format is described in [Table 26-45](#). The header is used only for memory booting. The peripheral booting image does not have any header and starts directly with executable code.

**Table 26-45. GP Device Software Image**

Field	Non-XIP Device	XIP Device	Size (Bytes)	Description
	Offset	Offset		
Size	0x0000	–	4	Size of the image
Destination	0x0004	–	4	Address where to store the image
Image	0x0008	0x0000	x	Image

### 26.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction in the initial software. The execution address is the first word after the image header. After the branch, the ARM runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting. [Table 26-46](#) shows the booting parameters structure.

**Table 26-46. Booting Parameter Structure**

Offset	Field	Size [Bytes]	Description
0x00	Booting message	4	Last received booting message
0x04	Current booting device	1	Code of device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x10: UART 0x11: HS USB Other: Reserved
0x05	Reserved	1	Reserved

**Table 26-46. Booting Parameter Structure (continued)**

Offset	Field	Size [Bytes]	Description
0x06	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: POR [1]: Global software reset [3]: Violation reset [4]: MPU watchdog reset [5]: Watchdog reset [6]: External warm reset Other bits: Reserved
0x07	CH flags	1	Configuration header sections flag. Each section is described by 1 bit. A set bit indicates that the section was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMC Other bits: Reserved
0x08	Device descriptor	4	Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called.

### 26.4.9 Tracing

Tracing in the public ROM code consists of a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. [Table 26-47](#) lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of startup.

There are two sets of tracing data: current trace information and tracing collected during the first ROM code run after a cold reset. This cold reset tracing is copied to its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging.

**Table 26-47. Tracing Vector**

Bit No.	Group	Meaning
0	General	Reset
1	General	ROM code C main
2	General	ROM code runs after the cold reset
3	Boot	Booting started
4	Memory boot	Memory booting started
5	Boot	No more device to check
6	Peripheral boot	Peripheral booting started
7	Boot	Booting message change device
8	Boot	Booting message skip per. booting
9	Reserved	Reserved
10	Memory boot	CH found
11	Memory boot	Image header correct
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC ID sent
14	Peripheral boot	Booting message received
15	Peripheral boot	Image received
16	Peripheral boot	Peripheral booting failed

**Table 26-47. Tracing Vector (continued)**

Bit No.	Group	Meaning
17	Peripheral boot	UART
18	Peripheral boot	USB
19	Reserved	Reserved
20	Reserved	Reserved
21	Peripheral boot	NULL device
22	Execute	Image executed
23	Reserved	Reserved for non-GP devices
24	Reserved	Reserved for non-GP devices
25	Reserved	Reserved for non-GP devices
26	Reserved	Reserved for non-GP devices
27	Reserved	Reserved for non-GP devices
28	Reserved	Reserved for non-GP devices
29	Boot	Software booting configuration section 1 found
30	General	Software booting configuration clocking section found
31	Reserved	Reserved
32	Memory boot	Null device
33	Memory boot	XIP
34	Memory boot	NAND
35	Memory boot	OneNAND
36	Memory boot	DOC
37	Memory boot	MMC/SD2
38	Memory boot	MMC/SD1
39	Memory boot	XIP memory with wait monitoring

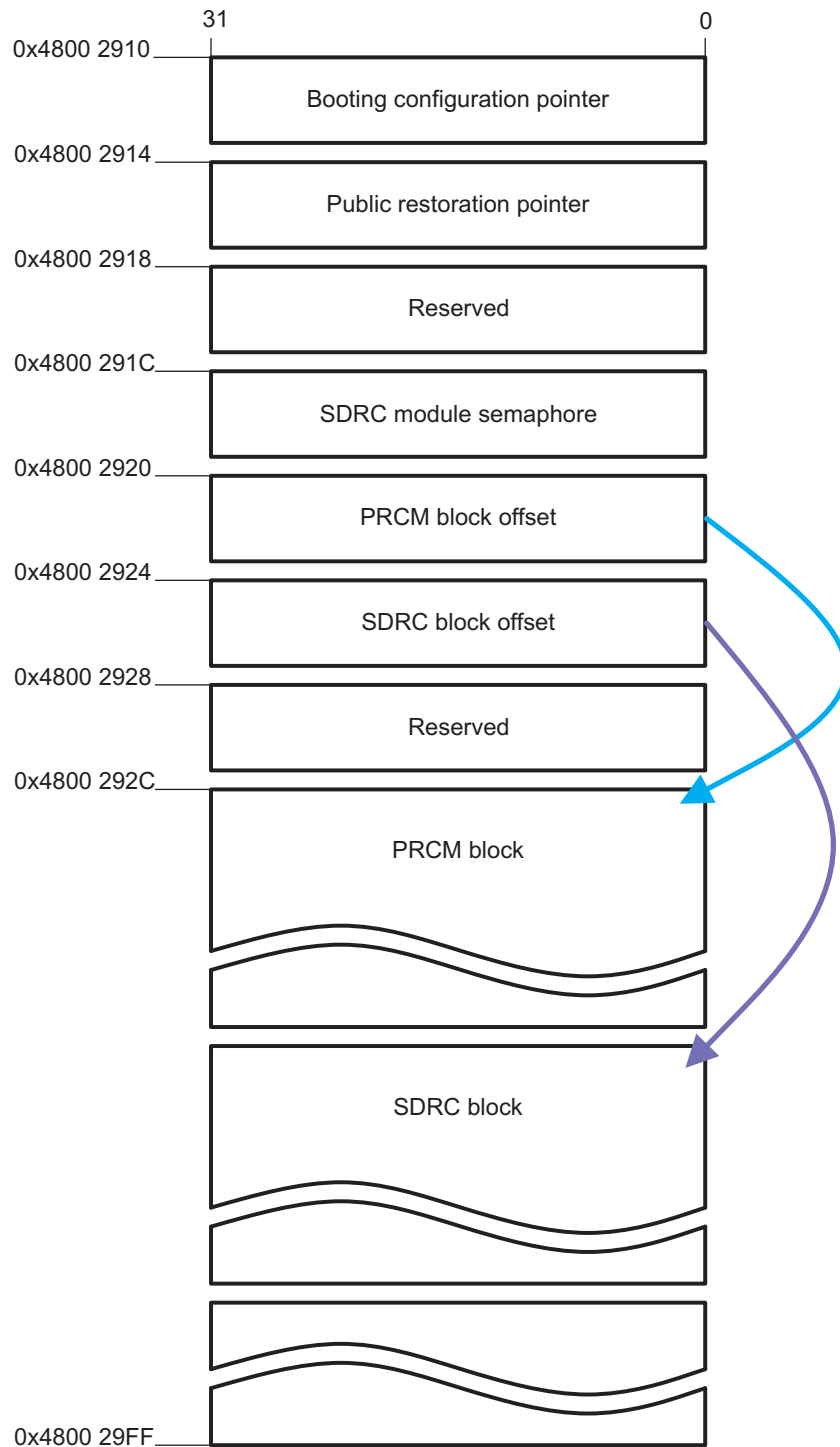

## 26.5 Wake-Up Booting by ROM Code

In CORE OFF power state, all configurations outside the WKUP power domain are reset and must be restored to restart the system in the condition it was in before being stopped. After an MPU and CORE power domain wake-up reset, the ROM code restores the SDRC and clock settings to allow a jump to a public restore function. This public restore function is specifically implemented by users to restore their own hardware and software environments. Users must set the public restore function address in the public restore pointer field of the CONTROL\_SAVE\_RESTORE\_MEM structure.

The CONTROL\_SAVE\_RESTORE\_MEM memory of the SCM saves and restores the mandatory information to automatically reconfigure the SDRC and PRCM registers. The SDRC and clock registers must be saved by users in the respective structures (see [Table 26-49](#) and [Table 26-50](#)) in the SCM (scratchpad memory) before going to off mode to be automatically restored on wake-up boot by the ROM code.

The size of CONTROL\_SAVE\_RESTORE\_MEM is 240 bytes starting at the hardware physical address 0x48002910 to 0x480029FF. [Figure 26-29](#) shows the memory format that must be obeyed to handle the context restoration.

**Figure 26-29. CONTROL\_SAVE\_RESTORE\_MEM Format**

init-021

**Table 26-48. CONTROL\_SAVE\_RESTORE\_MEM Field Definitions**

Field Name	Size	Description
Booting Configuration Pointer	32 bits	Address of public booting information used after a software reset

**Table 26-48. CONTROL\_SAVE\_RESTORE\_MEM Field Definitions (continued)**

Field Name	Size	Description
Public Restore Pointer <sup>(1)</sup>	32 bits	Address of the public restore function to branch to when exiting a wake-up reset boot
SDRC Module Semaphore <sup>(2)</sup>	32 bits	Semaphore used for accessing the SDRC module
PRCM Block Offset <sup>(1)</sup>	32 bits	Offset of the PRCM configuration in the control save restore memory. Set 0x0 to not use this block.
SDRC Block Offset <sup>(1)</sup>	32 bits	Offset of the SDRC configuration in the control save restore memory. Set 0x0 to not use this block.

<sup>(1)</sup> Field to be set by users

<sup>(2)</sup> ROM code use only

Table 26-49 describes the PRCM context restore block.

## 26.6 Debug Configuration

### 26.6.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the OMAP34xx device. The debug capability is accessible through the JTAG interface with a limited number of pins.

### 26.6.2 JTAG Port Signal Description

The OMAP3430 target debug interface uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK) to meet the clocking requirements of the ARM968 processor, and the two instrumentations pins (EMU0, EMU1). For more information, see [Table 26-51](#).

**Table 26-51. Debug POR Signals**

Pin	Type <sup>(1)</sup>	Name	Description
nTRST	I	Test logic reset	When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface
TCK	I	Test clock	This is the test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to OMAP34xx, this is a free-running clock or a gated clock, depending on RTCK monitoring.
RTCK	O	Returned test clock	Synchronized TCK. Depending on the emulator attached to OMAP3430, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
TMS	I	Test mode select	Directs the next state of the IEEE 1149.1 TAP state-machine
TDI	I	Test data input	Scan data input to the device.
TDO	O	Test data output	Scan data output of the device.
EMU0	I/O	Emulation 0	Channel 0 trigger: Boot mode
EMU1	I/O	Emulation 1	Channel 1 trigger: Boot mode

<sup>(1)</sup> I = Input, O = Output

The power domain containing the debug logic can be switched OFF in normal operating mode to reduce power consumption.

#### CAUTION

Before starting the debugger, the DEBUG power domain must be activated by applying a minimum of 10 TCK pulses to the OMAP3430 device after nTRST is pulled high. To prevent the JTAG\_TMS pin from floating when the EMU power domain is off, add an external pullup (10 kΩ) on this pin.

### 26.6.3 Initial Scan Chain Configuration

The general-purpose ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to serially link to 16 TAP controllers or to individually scan one TAP controller without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the OMAP34xx device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins should be pulled high at POR to configure the initial scan chain of the OMAP34xx device to TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

### 26.6.4 Adding TAPs to the Scan Chain

The TAP router must be programmed to add TAPs to the scan chain (used in Design For Test). The following JTAG scans must be completed before the CoreSight debug access port (DAP) is added to the scan chain. CoreSight is the on-chip debug and trace ARM technology. IR and DR are the instruction register and the data register, respectively.

```
## Function : Update the JTAG preamble and post-amble counts.
Parameter : The IR pre-amble count is '0'.
Parameter : The IR post-amble count is '0'.
Parameter : The DR pre-amble count is '0'.
Parameter : The DR post-amble count is '0'.
Parameter : The IR main count is '6'.
Parameter : The DR main count is '1'.

## Function : Do a send-only JTAG IR/DR scan.
Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-ir'.
Parameter : The JTAG destination state is 'pause-ir'.
Parameter : The bit length of the command is '6'.
Parameter : The send data value is '0x00000007'.
Parameter : The actual receive data is 'discarded'.

## Function : Do a send-only JTAG IR/DR scan.
Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-dr'.
Parameter : The JTAG destination state is 'pause-dr'.
Parameter : The bit length of the command is '8'.
Parameter : The send data value is '0x00000089'.
Parameter : The actual receive data is 'discarded'.

## Function : Do a send-only JTAG IR/DR scan.
Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-ir'.
Parameter : The JTAG destination state is 'pause-ir'.
Parameter : The bit length of the command is '6'.
Parameter : The send data value is '0x00000002'.
Parameter : The actual receive data is 'discarded'.

## Function : Embed the POR address in next command.
Parameter : The POR address field is '0x0f000000'.
Parameter : The POR address value is '3'.

## Function : Do a send-only JTAG IR/DR scan.
Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-dr'.
Parameter : The JTAG destination state is 'pause-dr'.
Parameter : The bit length of the command is '32'.
Parameter : The send data value is '0xa3002108'.
Parameter : The actual receive data is 'discarded'.
```

```

## Function : Do a send-only all-ones JTAG IR/DR scan.
Parameter : The JTAG shift state is 'shift-ir'.
Parameter : The JTAG destination state is 'run-test/idle'.
Parameter : The bit length of the command is '6'.
Parameter : The send data value is 'all-ones'.
Parameter : The actual receive data is 'discarded'.

## Function : Wait for a minimum number of TCLK pulses.
Parameter : The count of TCLK pulses is '10'.

## Function : Update the JTAG preamble and post-amble counts.
Parameter : The IR pre-amble count is '0'.
Parameter : The IR post-amble count is '6'.
Parameter : The DR pre-amble count is '0'.
Parameter : The DR post-amble count is '1'.
Parameter : The IR main count is '4'.
Parameter : The DR main count is '1'.

```

After the DAP is added to the scan chain, the debugger can communicate with the Cortex-A8 processor.

### 26.6.5 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the OMAP34xx bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. [Table 26-52](#) lists the modules that are mapped to the DAP address, and the address space detail.

**Table 26-52. Debugger Address Space**

Start Addr (Hex)	End Addr (Hex)	Size	Description
0xD401 0000	0xD401 0FFF	4KB	ARM embedded trace macrocell (ETM) module
0xD401 1000	0xD401 1FFF	4KB	Cortex-A8 module
0xD401 9000	0xD401 9FFF	4KB	Trace port interface unit (TPIU)
0xD401 B000	0xD401 BFFF	4KB	ARM embedded trace buffer (ETB) module

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0xD401 D030 in the DAP-APB address space.

## Glossary

---

---

---

### Numerical

**2D**— Two dimensional

**3D**— Three dimensional

**3GPP**— 3rd Generation Partnership Project

### A

**ABS**— Absolute value

**ADC**— Analog-to-digital converter/conversion

**AEW**— Adaptive multirate

**AHB**— Advanced high-performance bus

**AMR**— Adaptive multirate; also Audio modem riser: An Intel specification that defines a new architecture for the design of motherboards.

**APB**— Advanced peripheral bus

**APE**— Applicative processor engine

**API**— Application programming interface; also ARM port interface

**ARAU**— Auxiliary register arithmetic unit

**ARGB**— Alpha, red, green, blue

**ASIC**— Application-specific integrated circuit: A chip built for a specific application. In the context of this document, ASIC refers to the FPGA that resides on the EVM board.

**ASCII**— American standard code for information

**ATR**— Answer to reset

**AVC**— Advanced video coding (MPEG4 - Part 10 also known as H264)

**AXI**— Advanced extensible interface

### B

**BB**— Busy bus

**BCD**— Binary-coded decimal: A representation of decimal digits (0–9) using a nibble that uses a certain number of bits. For example, using 4 bits, two BCDs can be packed into 1 byte.

**BGA**— Ball grid array

**BGAPTS**— Band gap voltage and temperature sensor

**BGT**— Block guard time

## C

**BIOS**— Built-in operating system

**BIST**— Built-in self-test

**Bluetooth®**— A short-range radio technology designed to simplify communications among network devices and between devices and the Internet. It also simplifies data synchronization between network devices and other computers.

**BPP**— Bits per pixel

**BTA**— Bus turn around

## C

**CALU**— Central arithmetic logic unit

**CAVLC**— Context-adaptive variable length coder

**CAVLD**— Context-adaptive variable length decoder

**CBUFF**— Circular buffer

**CDL**— Controlled delay line

**CE**— Chip enable

**CH**— Configuration header. To use settings other than ROM code defaults, (that is, clock frequencies, SDRAM/DDRAM settings, or GPMC settings).

**CID**— Card identification number

**CIF**— Common intermediate format. A video format used in video conferencing systems that easily supports both NTSC and PAL signals. CIF is part of the ITU H.261 video conferencing standard. It specifies a data rate of 30 fps, with each frame containing 288 lines and 352 pixels per line.

**CLE**— Command latch enable

**CLK**— Clock

**CLUT**— Color look-up table

**CMOS**— Complementary metal oxide semiconductor

**CMT**— Cellular mobile telephone

**Codec**— Coder/decoder or compression/decompression: A device that codes in one direction of transmission and decodes in another direction of transmission.

**ConnID**— Connection identifier: An initiator module identifier. A ConnID transmitted in-band with the request and is used for protection and error logging mechanism.

**CP15**— Coprocessor 15: This coprocessor controls the operation and configuration of the TI925T.

**CPSR**— Current program status register

**CPU**— Central processing unit: The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data and program memory addresses. The CPU includes the CALU, the multiplier, and the ARAU.

**CRC**— Cyclic redundancy check

**CS**— Chip-select

**CTRL**— Control

**CVBS**— Composite video broadcast signal

**CWT**— Command wire tracer

**D**

**D2D**— Die-to-die

**DAC**— Digital-to-analog converter

**DBB**— Digital baseband

**DBI**— Display data interface

**DCS**— Display command set

**DCO**— Digitally controlled oscillator

**DCT**— Discrete cosine transform: A fast Fourier transform used to manipulate compressed still and moving picture data.

**DDR**— Dual data rate

**DE**— Data enable

**DFF**— Digital flip-flop

**DFT**— Design for test

**DI**— Data identifier

**DISPC**— Display controller

**DLL**— Delay-locked loop

**DMA**— Direct memory access: A mechanism whereby a device other than the host processor contends for and receives mastery of the memory bus so that data transfers can occur independent of the host.

**DMC**— Data memory controller

**DPD, DPDM**— Deep power-down mode

**DPF**— Dynamic power framework

**DPI**— Display parallel interface. Digital implementation of PLL

**DPLL**— Digital phase-locked loop

**DRD**— Dual role device

**DRDY**— Data ready

**DRM**— Digital rights management

**DSI**— Display serial interface

**DSP**— Digital signal processor: A semiconductor that manipulates discrete or discontinuous electrical impulses in a manner that implements a desired algorithm.

**DSS**— Display subsystem

**DT**— Data type

**DVFS**— Dynamic voltage and frequency scaling

## E

## E

- EAV**— End of active video
- ECC**— Error checking and correction; also error correction code.
- ED**— Endpoint descriptor
- EDC**— Error detection code
- eFuse**— Electrical fuse: A one-time programmable memory location usually set at the factory
- EHCI**— Enhanced host controller interface
- EMC**— External memory controller
- EMI**— Electromagnetic interference
- EMV**— Initial letters of Europay, MasterCard, and VISA, the three companies which originally cooperated to develop the EMV standard
- EOF**— End of frame
- EOT**— End of transfer
- ES**— Erase status
- ETB**— Embedded trace buffer
- ETSI**— European Telecommunications Standard Institute
- ETM**— Embedded trace macrocell

## F

- FC**— Frame counter
- FE**— Framing error: An error that occurs when the asynchronous serial port receives a data character that does not have a valid stop-bit.
- FIFO**— First in first out: A queue; a data structure or hardware buffer from which items are removed in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver which are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).
- FIQ**— Fast interrupt request
- FlatLink™ 3G**—A Texas Instruments display interface protocol
- FS**— Frame synchronization
- FSM**— Finite state-machine: A model of computation consisting of a set of states, a start state, an input alphabet, and a transition function that maps input symbols and current states to a next state.
- FSR**— Fault status register
- FT**— Feed through

## G

- GDD**— Generic distributed DMA
- GP device**—General-purpose device
- GPIO**— General-purpose input/output: Pins that can accept input signals and/or send output signals but are not linked to specific uses.

**GPMC**— General-purpose memory controller

**GSM**— Global system for mobile communications

## H

**HC**— Host controller

**HDTV**— High-definition television

**HFP**— Horizontal Front Porch

**HNP**— Host Negotiation Protocol

**HPI**— Host port interface

**HS**— High speed

**HSEC**— Horizontal sync end code

**HSSC**— Horizontal sync start code

**HSYNC**— Horizontal synchronization: A bidirectional horizontal timing signal occurring once per line with a pulse width defined as an integral number of FCLK periods. Synchronization signals can be used to enable retrace of the electron beam of a display screen. Also HS.

**HSW**— Horizontal Synchronization Pulse Width

**HVGA**— Half-size video graphics array. One-half the resolution of VGA

**HW, H/W**— Hardware

**HWA**— Hardware accelerators

## I

**I<sup>2</sup>C**— Inter-integrated circuit: A multimaster bus where multiple chips can be connected. Each chip can act as a master by initiating a data transfer.

**I2S**— Inter-IC sound: A digital audio interface standard.

**IA**— Initiator agent, also Identifier address

**IC**— Integrated circuit

**ICR**— Intersystem communication registers

**IF**— Interface

**INT**— Interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.

**INTC**— Interrupt controller

**I/O**— Input/output

**IP**— Intellectual property

**IPC**— Interprocessor communication. Also referred to as *mailbox*.

**IrDA**— Infrared Data Association: Represents the group of device manufacturers that developed a standard for transmitting data via infrared light waves.

**IRQ**— Interrupt request: IRQs are hardware lines over which devices can send interrupt signals to the microprocessor.

## J

**ISO**— Isochronous: This refers to processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed and to ensure that the audio is synchronized with the video. Also, *International Standards Organization*.

**ISP**— Image sensing product; also image signal processor

**ISR**— Interrupt service routine: A function or set of functions that are called when an interrupt is encountered.

**ITU**— International Telecommunications Union

**IVA**— Image and video accelerator

## J

**JPEG**— Joint Photographics Experts Group

**JTAG**— Joint Test Action Group: The JTAG was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, IEEE Standard Test Access Port, and Boundary-Scan Architecture.

## K

**Kb**— Kilobits

**KB**— Kilobyte, 1024 B

**Kbps**— Kilobits per second

## L

**L1**— Level 1 cache/memory

**L2**— Level 2 cache/memory

**L3**— First level of interconnect in OMAP platform

**L4**— Second level of interconnect in OMAP platform

**LCD**— Liquid crystal display: A display that uses two sheets of polarizing material with a liquid crystal solution between them.

**LCh**— Logical DMA channel

**LDM**— Load multiple

**LDO**— Low dropout

**LH**— Local host

**LINK**— Link layer device

**LLP**— Low-level protocol

**LP**— Low power, operation mode for PHY

**LPDDR**— Low-power, double-data rate (SDRAM)

**LPM**— Low-power mode

**LPP**— Lines per panel

**LPSDR**— Low-power, single-data rate (SDRAM)

**LRC**— Longitudinal redundancy check

**LRU**— Least recently used

**LS**— Level shifter; also low speed

**LSB**— Least-significant bit

**LUT**— Look-up table

**LVDS**— Low-voltage differential signaling

## M

**Mailbox**— See *IPC*

**Mb**— Megabit

**Mbps**— Megabits per second

**McBSP**— Multichannel buffered serial port: An enhanced buffered serial port that includes the following standard features: buffered data registers, full duplex communication, and independent clocking and framing for receive and transmit. In addition, the McBSP includes the following enhanced features: internal programmable clock and frame generation, multichannel mode, and general-purpose I/O.

**MCSPi**— Multichannel serial port interface

**MCP**— Multi-chip package

**MCU**— Microcontroller unit (refers to the MPU)

**MDDR**— Mobile double-data-rate SDRAM, dedicated to mobile applications

**MIPI®**— Mobile industry processor interface

**MMC**— Multimedia card

**MMC/SD**— Multimedia card/secure data

**MMU**— Memory management unit: The MMU performs virtual-to-physical address translations, performs access permission checks for access to the system memory, and provides the flexibility and protection required for the OS to manage a shared physical memory space between the two processors.

**MPEG**— Motion Pictures Expert Group: A compression scheme for full-motion video.

**MPEG1**— The first MPEG compression scheme specification

**MPEG4**— The most current MPEG compression scheme specification, intended for very narrow bandwidths.

**MPU**— Microprocessor unit

**MS**— Mobile station

**MSB**— Most-significant bit: The highest order bit in a word. The plural form (MSBs) refers to a specified number of high-order bits, beginning with the highest order bit and counting to the right. For example, the 8 MSBs of a 16-bit value are bits 15 through 8.

**MUX**— Multiplex/multiplexer

**Muxed pin**— A pin is muxed when its pin control register field can be reconfigured by software to change the function associated with the pin.

**MuxMode**— A 3-bit field of the pin control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

## N

**N/A**— Not applicable

**NAK**— Not acknowledged

**NAND**— NAND flash memory that is a high-capacity, low-cost, embedded, permanent data storage solution

**NF**— Noise filter

**NMI**— Nonmaskable interrupt: An interrupt that cannot be masked or disabled.

**NOP**— No operation (DSP/CPU instruction)

**NR**— Noise reduction

**NSC**— National Semiconductor Corporation

**NTSC**— National Television System Committee (television broadcast system)

## O

**OCM**— On-chip memory

**OCO**— One change only

**OCP**— Open-core protocol

**OCPI**— Open-core protocol interface

**OEM**— Original equipment manufacturer

**OpenGL**— Open GL (programming API) enable

**OHCI**— Open host controller interface: This is an industry standard USB host controller interface.

**OMAP**— An open software and hardware platform targeted at second- and third-generation cellular phones with multimedia capabilities.

**OneNand™**— A memory chip based on NAND architecture integrating SRAM buffers and NOR logic interface. It combines the advanced data storage function of NAND flash with fast read speed function of NOR flash.

**OTG**— On-the-go (USB 2.0 specification)

## P

**PBIAS**— PMOS bias transistor to provide the bias voltage to extended drain I/Os

**PCB**— Printed circuit board

**PCLK**— Pixel clock

**PCM**— Pulse code modulation: A technique for digitizing speech by sampling the sound waves and converting each sample into a binary number.

**PDA**— Personal digital assistant

**PDE**— Personal down enable

**PE**— Packet end

**PF**— Packet footer

**PH**— Packet header

**PG**— Protection group

- 
- PGA**— Pin grid array
- PHY**— Physical layer device
- PI**— Packet identifier
- PID**— Protocol identifier: The PID register is used in Windows CE mode only.
- PLD**— Programmable logic device
- PLL**— Phase-locked loop: A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).
- PMC**— Program memory controller
- POP**— Package-on-package technology
- PMP**— Power management port
- POR**— Power-on reset
- PPI**— Physical layer protocol interface
- PPS**— Protocol and parameter selection
- PRCM**— Power, reset, and clock management
- PRM**— Power and reset manager
- PS**— Packet start
- PSA**— Parallel signature analyzer
- PT**— Packet type
- PVT**— Process, voltage, and temperature (that is, PVT dispersion)
- PWB**— Printed wiring board
- PWM**— Pulse width modulation
- PWR**— Power

**Q**

- QCIF**— Quarter common intermediate format: A video conferencing format that specifies data rates of 30 fps, with each frame containing 144 lines and 176 pixels per line. This is one-fourth the resolution of CIF. QCIF support is required by the ITU H.261 video conferencing standard.
- QVGA**— Quarter video graphics array (one-fourth the resolution of VGA).

**R**

- R**— Read only
- RBL**— Read buffer logic
- RFBI**— Remote frame buffer interface
- RFU**— Reserved for future use
- RGB**— Red, green, blue
- RGBA**— Red, green, blue, alpha
- ROM**— Read only memory: A semiconductor storage element containing permanent data that cannot be changed.

**RST**— Reset  
**RT**— Real-time  
**RVLC**— Reversible variable length coder  
**RVLD**— Reversible variable length decoder  
**R/W**— Read/write  
**RX**— Receive/receiver

## S

**S3220**— Abbreviation of Sonics3220. It refers to the L4 interconnect.

**SAM**— Shared access mode: The mode that allows both the DSP and the host to access host port interface (HPI) memory. In this mode, asynchronous host accesses are synchronized internally, and, in case of conflict, the host has access priority and the DSP waits one cycle.

**SAR**— Save and restore: Hardware context saving for power saving

**SAV**— Start of active video

**SCCB**— Serial camera control interface: 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

**SCL**— Serial clock: Programmable serial clock used in the I<sup>2</sup>C interface. Also SCLK.

**SCM**— Scan combiner module; also statistic collection module

**SCP**— Serial configuration port

**SD**— Starting delimiter

**SDA**— Serial data: Serial data bus in the I<sup>2</sup>C interface.

**SDI**— Serial display interface

**SDIO**— Secure digital input/output

**sDMA**— System direct memory access

**SDR**— Single data rate

**SDRC**— SDRAM controller

**SDRAM**— Synchronous dynamic random access memory

**SDTI**— System debug trace interface

**SDTV**— Standard digital television

**SGX**— Abbreviation for graphic accelerator (GFX in ES1.0)

**SIM**— Subscriber identity module

**SIMD**— Single instruction multiple data

**SILVS**— Scalable low-voltage signaling

**SMS**— SDRAM memory scheduler

**SMX**— Abbreviation of SonicsMX. It refers to the L3 interconnect.

**SNR**— Signal-to-noise ratio

**SOF**— Start of frame

**SOT**— Start of transmission

**SRAM**— Static random access memory. Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.

**SRG**— Sample rate generator

**SRP**— Session request protocol

**SRRP**— Session RAM restoration pointer

**SS**— Subsystem

**SSR**— Serial synchronous receiver

**SST**— Serial synchronous transmitter

**ST**— Start timer

**STM**— Synchronous transfer mode; also store multiple

**STN**— Super-Twist Nematic: A technique for improving LCD display screens by twisting light rays.

**SVGA**— Super video graphic adapter

**SW**— Software

**SWI**— Software interrupt

## T

**TC**— Traffic controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.

**TCK**— Test clock

**TD**— Transfer descriptor

**TDM**— Time division multiplex/multiplexing: The process by which a single serial bus is shared by multiple devices with each device taking turns to communicate on the bus. The total number of time slots (channels) depends on the number of devices connected. During a time slot, a given device may talk to any combination of devices on the bus.

**TFT**— Thin film transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.

**TLB**— Translation lookaside buffer: A cache that contains entries for virtual-to-physical address translation and access permission checking.

**TLL**— Transceiverless link: This is logic that lets the user connect two USB transceiver interfaces together directly without the use of differential transceivers.

**TM**— Target module: A target module cannot generate read/write requests to the chip interconnects, but it responds to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

**TOC**— Table of contents

**TRM**— Technical reference manual

**TRX**— USB transceiver: The USB analog driver/receiver.

**TTB**— Translation table base: It points to the base of a table in physical memory that contains section and page table descriptors.

**TWL**— Table walking logic

## U

**TX**— Transmit/transmitter

## U

**UART**— Universal asynchronous receiver/transmitter: Another name for the asynchronous serial port.

**UICC**— Universal integrated circuit card

**ULPM**— Ultra-low power mode

**ULPI**— UTMI+ low pincount interface

**ULPS**— Ultra-low power state

**UMC**— United memory controller

**UNP**— Unpredictable

**USAR**— Universal synchronous/asynchronous receiver

**USART**— Universal synchronous/asynchronous receiver/transmitter

**USB**— Universal serial bus: An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

**UTMI**— USB 2.0 transceiver macrocell interface

**UTMI+**— UTMI extension supporting USB host and on-the-go

## V

**VA**— Volt-amps: A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

**VC**— Virtual channel

**VENC**— Video encoder

**VESA**— Video Electronics Standards Association

**VFP**— Vertical front porch

**VGA**— Video graphics array: An industry standard for video cards.

**VLC**— Variable length decoder

**VLD**— Variable length coder

**VMODE**— Bi-level voltage control interface

**VPBE**— Video processing back end

**VSEC**— Vertical synchronization end code

**VSSC**— Vertical synchronization start code

**VSYNC, VS**— Vertical synchronization: A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode).

## W

**WBL**— Write buffer logic

**WC**— Word count

**WD**— Watchdog: A timer that requires the user program or OS periodically write to the count register before the counter underflows.

**WDT**— Watchdog timer

**WLAN**— Wireless local area network

**WMV**— Windows media video

**WMA**— Windows media audio

**Word16**— 16-bit word

**Word32**— 32-bit word

**WP**— Write protect

**WSS**— Wide-screen signaling

**WWT**— Work waiting time

## X

**XGA, XVGA**— Extended graphics array

**XIP**— Execution in place

## Y

**YUV**— Luminance-Bandwidth-Chrominance

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
