<b>Address Offset</b>	0x0380 + (0x4*j)																																																																						
<b>Physical address</b>	0x01C0 0380 + (0x4*j)								Instance				IVA2.2 TPCC																																																										
<b>Description</b>	QDMA Region Access enable for bit N in Region i: En = 0: Accesses through Region i address space to Bit N in any QDMA Channel Register are not allowed. Reads will return b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region i interrupt. En = 1: Accesses through Region i address space to Bit N in any QDMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region i interrupt.

**Table 14-338. TPCC\_ER**

<b>Address Offset</b>	0x1000	
<b>Physical address</b>	0x01C0 1000	<b>Instance</b> IVA2.2 TPCC
<b>Description</b>	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

<b>Address Offset</b>	0x101C		
<b>Physical address</b>	0x01C0 101C	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Chained Event Register (High Part): If CERH.En bit is set (regardless of state of EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared through software.

<b>Physical address</b>	0x01C0 1020																																																														
<b>Description</b>	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EEER register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

<b>Address Offset</b>	0x1080		<b>Instance</b>	IVA2.2 TPCC	
<b>Physical address</b>	0x01C0 1080				
<b>Description</b>	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

<b>Address Offset</b>	0x2000 + (0x200*n) n = 0 to 7	
<b>Physical address</b>	0x01C0 2000 + (0x200*n) n = 0 to 7	<b>Instance</b> IVA2.2 TPCC
<b>Description</b>	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

<b>Address Offset</b>	0x2018 + (0x200*n) n = 0 to 7		
<b>Physical address</b>	0x01C0 2018 + (0x200*n) n = 0 to 7	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

<b>Physical address</b>	0x01C0 2020 + (0x200*n) n = 0 to 7	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

<b>Address Offset</b>	0x2080 + (0x200*n) n = 0 to 7	
<b>Physical address</b>	0x01C0 2080 + (0x200*n) n = 0 to 7	<b>Instance</b> IVA2.2 TPCC
<b>Description</b>	<p>QDMA Event Register:</p> <p>If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.</p>	
<b>Type</b>	R

BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum Number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of 0 is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.	RW	0x----
15:0	ACNT	ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to TC. An ACNT of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. <b>Bits</b>	<b>Field Name</b>																<b>Description</b>																<b>Type</b>																<b>Reset</b>															
31:16	DBIDX																Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2s complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.																RW																0x----															
15:0	SBIDX																Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2s complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between - 32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.																RW																0x----

BCNTRLD																LINK																																																
<b>Bits</b>	<b>Field Name</b>																<b>Description</b>																<b>Type</b>																<b>Reset</b>															
31:16	BCNTRLD																BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Synced transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not CC-thus BCNTRLD is a dont care field.																RW																0x----															

Bits	Field Name	Description	Type	Reset
15:0	LINK	<p>Link Address:                      The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to 0) with a new PaRAM Entry. This is called linking. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the literal byte address of the LINK parameter or the PaRAM base-relative address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., dont have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location.</p> <p>A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.</p>	RW	0x----

<b>Type</b>	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																TRDONE		PROGEMPTY													

Bits	Field Name	Description	Type	Reset
31:4	Reserved	Read returns 0.	R	0x0000000
3	MMRAERR	MMR Address Error: MMRAERR = 0: Condition not detected. MMRAERR = 1: User attempted to read or write to invalid address configuration memory map. (Is only be set for non-emulation accesses). No additional error information is recorded.	R	0
2	TRERR	TR Error: TR detected that violates FIFO Mode transfer (SAM or DAM is 1) alignment rules or has ACNT or BCNT == 0. No additional error information is recorded.	R	0
1	Reserved	Read returns 0.	R	0
0	BUSERR	Bus Error Event: BUSERR = 0: Condition not detected. BUSERR = 1: TC has detected an error code on the write response bus or read response bus. Error information is stored in Error Details Register (ERRDET).	R	0

<b>Address Offset</b>	0x12C	<b>Instance</b>	IVA2.2 TPTC0
<b>Physical address</b>	0x01C1 012C	<b>Instance</b>	IVA2.2 TPTC1
<b>Physical address</b>	0x01C1 052C	<b>Instance</b>	IVA2.2 TPTC1
<b>Description</b>	Error Details Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TCCHEN	TCINTEN	Reserved	TCC					Reserved				STAT					

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Read returns 0.	R	0x0000
17	TCCHEN	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
16	TCINTEN	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
15:14	Reserved	Read returns 0.	R	0x0
13:8	TCC	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x00
7:4	Reserved	Read returns 0.	R	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higherpriority. Encoding of errors matches the CBA spec and is summarized here: 0xF = Read 0x0: No Error (should not cause error to be latched) Read 0x1: Read Addressing error Read 0x2: Read Privilege error Read 0x3: Read Timeout error Read 0x4: Read Data error Read 0x7: Read Exclusive-operation failure Read 0x8: No Error (should not cause error to be latched) Read 0x9: Write Addressing error Read 0xA: Write Privilege error Read 0xB: Write Timeout error Read 0xC: Write Data error Read 0xF: Write Exclusive-operation failure	R	0x0

**Table 14-558. SYSC\_LICFG0**

<b>Address Offset</b>	0x040	<b>Instance</b>	IVA2.2 SYSC
<b>Physical address</b>	0x01C2 0040		
<b>Description</b>	This register controls various parameters of the IVA2.2 local interconnect network		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																GEMBURSTOPTEN	GEMTRUECOMPEN	Reserved						DMA2DOPTEN	DMATRUECOMPEN	Reserved				Reserved	PAGEXINGEN	Reserved

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
16	GEMBURSTOPTEN	DSP megamodule cache-line operation transfers optimization control: 0: DSP megamodule cache operation transfers are not optimized 1: DSP megamodule cache operation transfers are optimized	RW	0
15	GEMTRUECOMPEN	DSP megamodule program-initiated write-back transfer true completion control: 0: DSP megamodule program-initiated write-back transfer completion is not accurate 1: DSP megamodule program initiated write-back transfer completion is accurate	RW	0
14:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
9	DMA2DOPTEN	2D transfers optimization control: 0: 2D DMA transfers optimization is disabled 1: 2D DMA transfers optimization is enabled	RW	0
8	DMATRUECOMPEN	DMA write transfer true completion control: 0: DMA write transfer completion is not accurate 1: DMA write transfer completion is accurate	RW	0
7:4	Reserved	Write 0xF for compatibility. Read returns 0xF	RW	0xF
3:2	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
1	PAGEXINGEN	MMU page crossing enable: 0: Bursts are not allowed to cross 4KB page boundaries 1: Bursts are allowed to cross 4KB page boundaries	RW	0
0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0

**Table 14-560. SYSC\_LICFG1**

<b>Address Offset</b>	0x048	
<b>Physical address</b>	0x01C2 0048	<b>Instance</b> IVA2.2 SYSC
<b>Description</b>	This register allows controlling various parameters of the IVA2.2 local interconnect network	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																APINTERVAL															

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
4:0	APINTERVAL	Control of the Aged Priority (priority inversion) for DMA accesses: When set to 0x0, the aged priority is disabled  When set to another value, this controls how often the priority is adjusted: every APInterval cycles, the priority of the port is decreased until the associated request is accepted or the priority of the port equals 0. The priority of the port is reinitialized to the transaction priority each time a new VBUS command is generated, i.e. the last one has been accepted.  0x0: Aged Priority Disabled: There is no aged priority in SCR. DMA transaction keeps the fixed priority defined internally, and has to wait for the bus to be freed by higher priority initiators	RW	0x00

## 14.5.9 SEQ Registers

This section provides information about the SEQ Module. Each register in the module is described separately below.

### 14.5.9.1 SEQ Register Mapping Summary

**Table 14-601. SEQ Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
SEQ_REVISION	R	32	0x0000 0000	0x0009 0000
SEQ_SYSCONFIG	RW	32	0x0000 0008	0x0009 0008
SEQ_IRQMASK	RW	32	0x0000 0040	0x0009 0040
SEQ_IRQCLR	W	32	0x0000 0044	0x0009 0044
SEQ_IRQSET	W	32	0x0000 0048	0x0009 0048
SEQ_IRQSTATE	R	32	0x0000 004C	0x0009 004C
SEQ_SWICLR	W	32	0x0000 0060	0x0009 0060
SEQ_SWISET	W	32	0x0000 0064	0x0009 0064
SEQ_SWISTATE	R	32	0x0000 0068	0x0009 0068

**14.5.9.2 SEQ Register Descriptions****Table 14-602. SEQ\_REVISION**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	SEQ
<b>Physical Address</b>	0x0009 0000		
<b>Description</b>	This register contains the IP revision code (reset value to be defined by design team for each version of the module)		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 14.5.10 Video System Controller Registers

This section provides information about the Video System Controller module. Each register in the module is described separately below.

### 14.5.10.1 Video System Controller Register Mapping Summary

**Table 14-620. VIDEOSYSC Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
VIDEOSYSC_REVISION	R	32	0x0000 0000	0x0009 C000
VIDEOSYSC_SYSCONFIG	RW	32	0x0000 0008	0x0009 C008
VIDEOSYSC_IRQMASK	w/1toSet	32	0x0000 0040	0x0009 C040
VIDEOSYSC_IRQCLR	w/1toSet	32	0x0000 0044	0x0009 C044
VIDEOSYSC_IRQSET	w/1toSet	32	0x0000 0048	0x0009 C048
VIDEOSYSC_IRQSTATE	w/1toSet	32	0x0000 004C	0x0009 C04C
VIDEOSYSC_CLKCTL	W	32	0x0000 0060	0x0009 C060
VIDEOSYSC_CLKDIV	RW	32	0x0000 0064	0x0009 C064
VIDEOSYSC_CLKST	R	32	0x0000 0068	0x0009 C068

<b>Address Offset</b>	0x0000 0060																																																						
<b>Physical Address</b>	0x0009 C060	<b>Instance</b> VIDEOSYSC																																																					
<b>Description</b>	Video accelerator clock control: Writing a 0 forces the module to leave the idle state (modules input clock goes active) Writing a 1 requests the module enter the idle state when no request/commands pending for the module. (Allows module input clock to be stopped). Module automatically exits the idle state and clock starts each time new requests/commands are present. Clock status can be checked in <a href="#">VIDEOSYSC_CLKST</a> register																																																						
<b>Type</b>	W

### 14.5.11 iME Registers

This section provides information about the improved Motion Estimation module. Each register in the module is described separately below.

#### 14.5.11.1 iME Register Mapping Summary

**Table 14-639. iME Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
iME_REVISION	R	32	0x0000 0000	0x000A 0000
iME_SYSCONFIG	RW	32	0x0000 0010	0x000A 0010
iME_SYSSTATUS	R	32	0x0000 0014	0x000A 0014
iME_PROGRAMBUFFERLINENLSBi <sup>(1)</sup>	RW	32	0x0000 0040 + (0x8*i)	0x000A 0040 + (0x8*i)
iME_PROGRAMBUFFERLINENMSBi <sup>(1)</sup>	RW	32	0x0000 0044 + (0x8*i)	0x000A 0044 + (0x8*i)
iME_ERRORTABLEj <sup>(2)</sup>	RW	32	0x0000 0840 + (0x4*j)	0x000A 0840 + (0x4*j)
iME_REFERENCEBLOCKk <sup>(3)</sup>	RW	32	0x0000 0880 + (0x4*k)	0x000A 0880 + (0x4*k)
iME_COEFFREGBANKl <sup>(4)</sup>	RW	32	0x0000 0980 + (0x4*l)	0x000A 0980 + (0x4*l)
iME_PARAMETERSTACKLj <sup>(2)</sup>	RW	32	0x0000 0990 + (0x4*j)	0x000A 0990 + (0x4*j)
iME_PARAMETERSTACKHj <sup>(2)</sup>	RW	32	0x0000 09D0 + (0x4*j)	0x000A 09D0 + (0x4*j)
iME_XMVCTm <sup>(5)</sup>	RW	32	0x0000 0AA0 + (0x4*m)	0x000A 0AA0 + (0x4*m)
iME_YMVCTm <sup>(5)</sup>	RW	32	0x0000 0AC0 + (0x4*m)	0x000A 0AC0 + (0x4*m)
iME_MINERRORTHRESHOLD	RW	32	0x0000 0AE0	0x000A 0AE0
iME_ABSMINREACHED	RW	32	0x0000 0AE4	0x000A 0AE4
iME_CPUSTATUSREG	R	32	0x0000 0AE8	0x000A 0AE8
iME_IRQLOG	R	32	0x0000 0AEC	0x000A 0AEC
iME_LATESTERRORS	RW	32	0x0000 0AF0	0x000A 0AF0
iME_CONFIGREG	RW	32	0x0000 0AF4	0x000A 0AF4
iME_SL2INSTADDRESS	RW	32	0x0000 0AF8	0x000A 0AF8
iME_COMMANDREG	W	32	0x0000 0FFC	0x000A 0FFC

(1) i = 0 to 255

(2) j = 0 to 15

(3) k = 0 to 63

(4) l = 0 to 3

(5) m = 0 to 7

**Table 14-642. iME\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	0x000A 0010	<b>Instance</b> iME
<b>Description</b>	This register allows controlling various parameters of the OCP interface	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	SIDLEMODE	RESERVED	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Read returns 0.	R	0x0
8	CLOCKACTIVITY	Clock activity during wake up mode period. 0 - OCP clock can be switched-off.	R	0x0
7:5	RESERVED	Read returns 0.	R	0x0
4:3	SIDLEMODE	Slave interface power management, req/ack control "10" = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of iME	R	0x2
2	RESERVED	Read returns 0.	R	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger the iME reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy: 0: OCP clock is free running 1: Automatic OCP clock-gating strategy is applied based on the OCP interface activity	RW	0x1

## 14.5.12 iLF Registers

This section provides information about the improved Loop Filter module. Each register in the module is described separately below.

### 14.5.12.1 iLF Register Mapping Summary

**Table 14-680. iLF Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
iLF_REVISION	R	32	0x0000 0000	0x000A 1000
iLF_SYSCONFIG	RW	32	0x0000 0010	0x000A 1010
iLF_SYSSTATUS	R	32	0x0000 0014	0x000A 1014
iLF_PROGRAMBUFFERLINENLSBi <sup>(1)</sup>	RW	32	0x0000 0040 + (0x8*i)	0x000A 1040 + (0x8*i)
iLF_PROGRAMBUFFERLINENMSBi <sup>(1)</sup>	RW	32	0x0000 0044 + (0x8*i)	0x000A 1044 + (0x8*i)
iLF_PARAMETERSTACKUPj <sup>(2)</sup>	RW	32	0x0000 0440 + (0x4*j)	0x000A 1440 + (0x4*j)
iLF_PARAMETERSTACKLWk <sup>(3)</sup>	RW	32	0x0000 0460 + (0x4*k)	0x000A 1460 + (0x4*k)
iLF_EFPTABLEENTRYl <sup>(4)</sup>	RW	32	0x0000 04C0 + (0x4*l)	0x000A 14C0 + (0x4*l)
iLF_INOUTBUFFERm <sup>(5)</sup>	RW	32	0x0000 0550 + (0x4*m)	0x000A 1550 + (0x4*m)
iLF_CPUSTATUSREG	R	32	0x0000 05F0	0x000A 15F0
iLF_IRQLOG	R	32	0x0000 05F4	0x000A 15F4
iLF_EFPTD	R	32	0x0000 05F8	0x000A 15F8
iLF_CONFIGREG	RW	32	0x0000 05FC	0x000A 15FC
iLF_PARSEDDATAREG0	RW	32	0x0000 0600	0x000A 1600
iLF_PARSEDDATAREG1	RW	32	0x0000 0604	0x000A 1604
iLF_PARSEDDATAREG2	RW	32	0x0000 0608	0x000A 1608
iLF_INSTBUFFER_ADDRESS	RW	32	0x0000 060C	0x000A 160C
iLF_LINESFILTERPROTOTYPES	R	32	0x0000 0610	0x000A 1610
iLF_CLIPLIMITSENTRYn <sup>(6)</sup>	R	32	0x0000 0614 + (0x4*n)	0x000A 1614 + (0x4*n)
iLF_COMMANDREG	W	32	0x0000 0FFC	0x000A 1FFC

<sup>(1)</sup> i = 0 to 127

<sup>(2)</sup> j = 0 to 7

<sup>(3)</sup> k = 0 to 23

<sup>(4)</sup> l = 0 to 35

<sup>(5)</sup> m = 0 to 39

<sup>(6)</sup> n = 0 to 3

### 14.5.12.2 iLF Register Descriptions

**Table 14-681. iLF\_REVISION**

<b>Address Offset</b>	0x0000 0000	
<b>Physical Address</b>	0x000A 1000	<b>Instance</b> iLF
<b>Description</b>	This register contains the iLF revision code	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0	R	0x0000000
7:0	REV	iLF Revision [3:0] Minor Revision [7:4] Major Revision	R	See <sup>(1)</sup>

<sup>(1)</sup> TI internal data

**Table 14-683. iLF\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	0x000A 1010	<b>Instance</b> iLF
<b>Description</b>	This register allows controlling various parameters of the OCP interface	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	SIDLEMODE	RESERVED	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Read returns 0.	R	0x0
8	CLOCKACTIVITY	Clock activity during wake up mode period. 0 - OCP clock can be switched-off.	R	0x0
7:5	RESERVED	read returns 0.	R	0x0
4:3	SIDLEMODE	Slave interface power management, req/ack control "10" = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of iME	R	0x2
2	RESERVED	read returns 0.	R	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger the iME reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy: 0: OCP clock is free running 1: Automatic OCP clock-gating strategy is applied based on the OCP interface activity	RW	0x1

**Table 14-699. iLF\_CPUSTATUSREG**

<b>Address Offset</b>	0x0000 05F0	
<b>Physical Address</b>	0x000A 15F0	<b>Instance</b> iLF
<b>Description</b>	CPU Status Register provides information about the progress of the CPU execution	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	DETECTEDENDOFFPGM	DETECTEDSTOPSEQ	ENDPGMERROR	OPCODEERROR	WRITEREGERROR	EXECSTATE	PC									CYCLECOUNT															

Bits	Field Name	Description	Type	Reset
31	RESERVED	Read returns 0.	R	0x0
30	DETECTEDENDOFFPGM	This bit is set to '1' when, in Debug mode, an EndPgm() instruction or the last instruction of the program buffer has been reached and it is not a LoadInstBuf() instruction. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
29	DETECTEDSTOPSEQ	This bit is set to '1' when a StopSeq() has been issued and the iME is in Halted state. Execution of StopSeq() is postponed to the time when the CPU gets out of the Halted state. This bit is cleared when the StopSeq() command is effectively executed.	R	0x0
28	ENDPGMERROR	This bit is set to '1' when the last instruction of the program buffer is reached and no EndPgm() or LoadInstBuf() instruction have been detected in the program buffer. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
27	OPCODEERROR	This bit is set to '1' when an unknown opcode is decoded from the main program. The following instruction of the sequence is then executed. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
26	WRITEREGERROR	This bit is set to '1' when attempting to write an internal register through an OCP write, while in EXECUTING state. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
25:24	EXECSTATE	Execution States: 00 = Initialized, 10 = Executing, 01 = Halted, 11 = Completed.	R	0x0
23:16	PC	Number of instruction currently executing. Bit #7 is always 0 (PC values range from 0x00 to 0x7f)	R	0x00
15:0	CYCLECOUNT	Total number of cycles executed.	R	0x0000

## 15.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Serial display interface (SDI) complex input/output (I/O) module with the associated phased-locked loop (PLL)
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider.
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

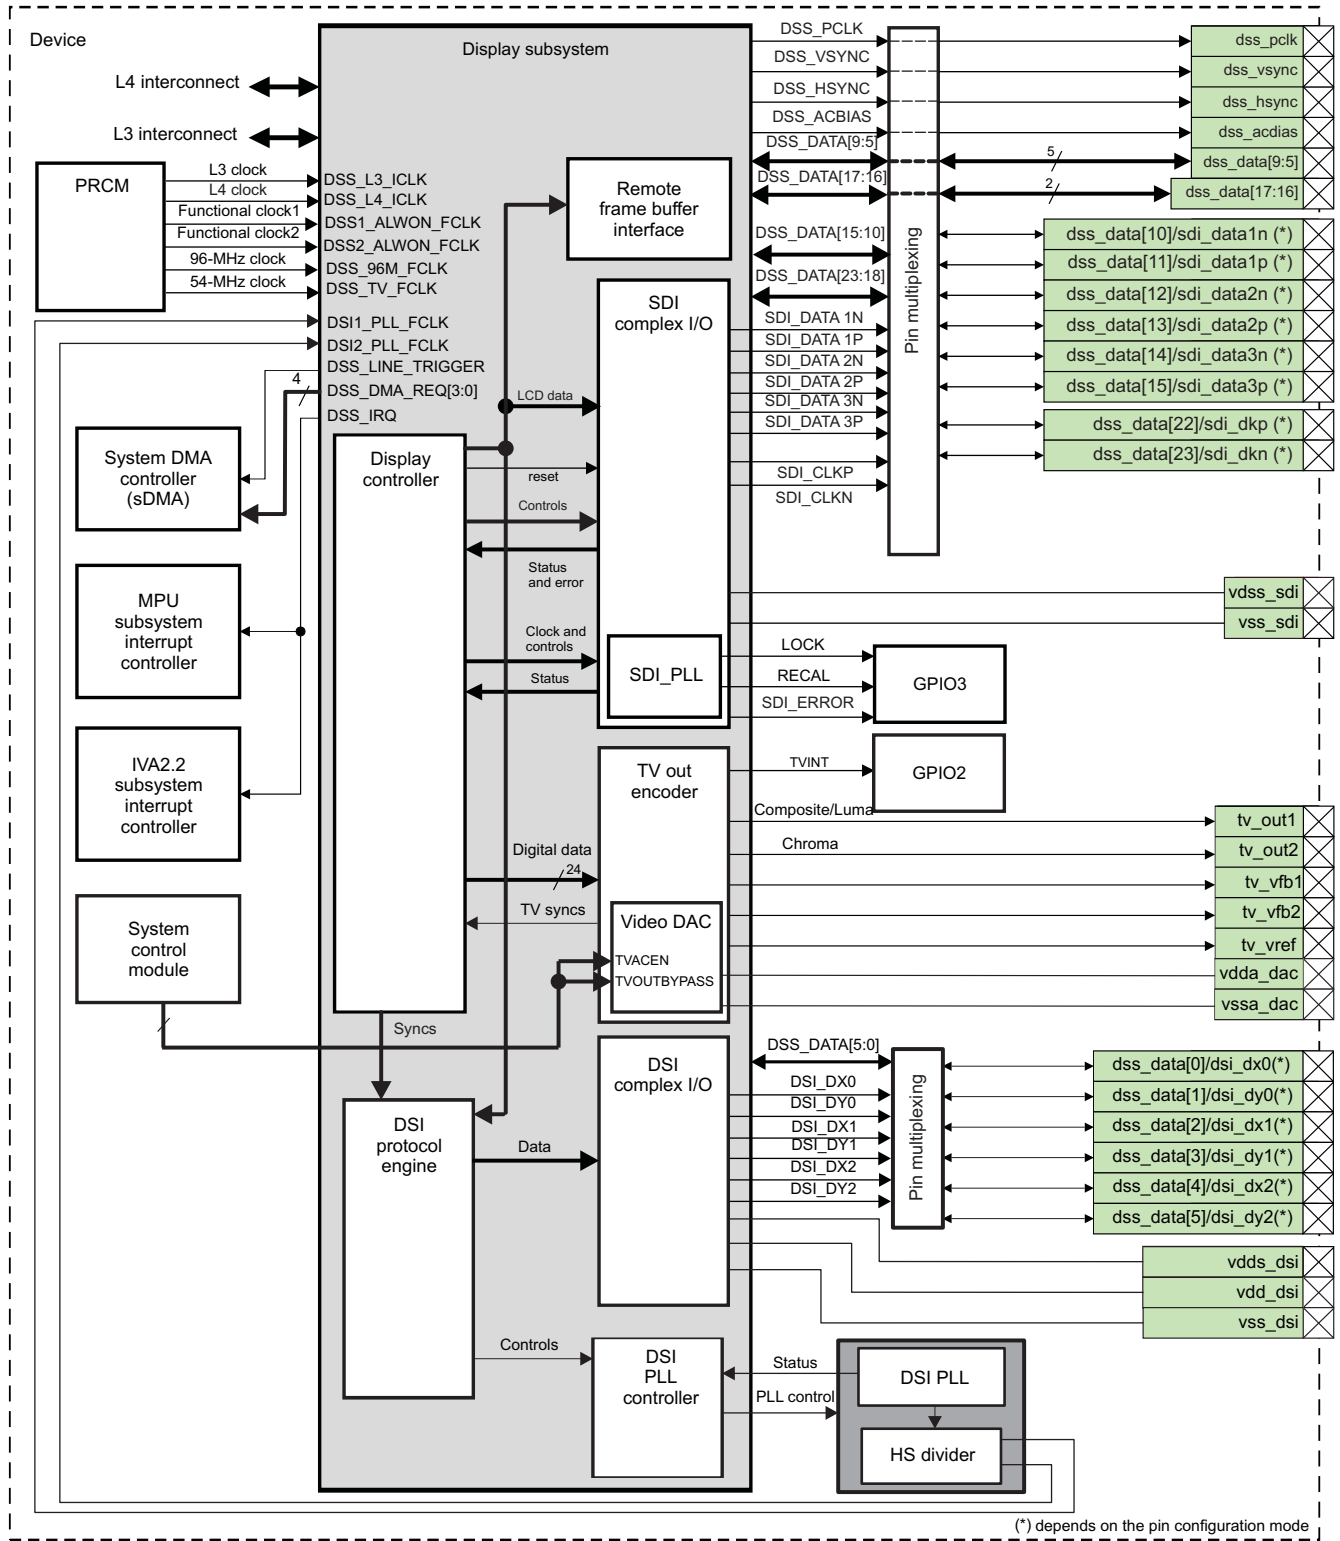

---

**Note:** The SDI module, the DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

---

Figure 15-1 shows a block diagram of the display subsystem.

Figure 15-1. Display Subsystem Highlight

(\*) depends on the pin configuration mode

dss-001

**Note:** For more information about connecting the LOCK, RECAL, SDI\_ERROR, and TVINT signals through the GPIO2 and GPIO3 modules, see [Chapter 25, GPIO](#).

The display subsystem includes the following main features:

- Display controller
  - Display modes
    - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
    - Programmable display size supported:
      - XGA - 1024 × 768 VESA timings at 60 fps (pixel clock = 63.5 MHz)
      - WXGA - 1280 × 800 VESA timings at 59.91 fps (pixel clock = 71 MHz)
      - SXGA+ - 1400 × 1050 direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75 MHz)
      - HD 720p - 1280 × 720 CEA 861-D timings at 60 fps (pixel clock = 74.25 MHz)
    - 256 × 24-bit entries palette in red, green, and blue (RGB)
    - Programmable pixel rate up to 75 MHz

---

**Note:** The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).

---

- Display support
  - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
  - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
  - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
  - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
  - Remote frame buffer support through the RFBI module
  - Partial display through the RFBI module
  - Second 24-bit digital output
  - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
  - HDMI through external bridge
- Signal processing
  - Overlay support for graphics (ARGB, RGBA, RGB, or Color Look-Up Table (CLUT)) and video1 (YCbCr 4:2:2, or ARGB, RGBA, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
  - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on input height
  - Rotation 90-, 180-, and 270-degrees
  - Transparency color key (source and destination)
  - Synchronized buffer update
  - Programmable video color space conversion YCbCr 4:2:2 into RGB
  - Hardware cursor
  - Gamma curve support on LCD output
  - Multiple-buffer support
  - Mirroring support
  - Programmable color phase rotation (CPR)
  - Alpha blending support (no rescaling in ARGB or RGBA formats)
- Advanced
  - Self-refresh using the DMA FIFO
  - Arbitration between high/low priority (graphics video1 and video2)
  - FIFO handcheck in STALL mode
- Power modes: Low-power saving modes

- RFBI (MIPI® DBI protocol)
  - Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
    - Sends commands to the RFB panel through the L4 interconnect
    - Sends data, received from the display controller or from the MPU through the DISPC pixel data bus, to the RFB panel
    - Reads data/status from the RFB to the L4 interconnect
  - RFB interface
    - 8-/9-/12-/16-bit 8086-series parallel interface
    - Two programmable configurations for two devices connected to the RFBI module
  - Data formats
    - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
    - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
  - Interconnect/FIFO
    - One slave port with DMA request and interconnect FIFO of 24x32-bit depth (for write access to DSS.RFBI\_DATA register only)
    - One video port FIFO of 8 × 24-bit depth receiving data from the display controller
- SDI
  - TI Flatlink™ 3G display interface support
  - Pin multiplexing allows simultaneous operation with a single 9-bit RFBI-driven display (no support for simultaneous dual RFBI panel and SDI)

---

**Note:** The SDI pins are multiplexed with LCD parallel outputs.

---

- MIPI DSI
  - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI DSI\_PHY
  - The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage.
  - Supports video mode and command mode
  - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  - Supports up to two data-configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
  - Maximum data rate of 800 Mbps per data pair
  - Data splitter for 2-data lane configuration
  - Error-correction code (ECC) and check-sum generation
  - Burst support for the video mode
  - RGB16, RGB18 packed and nonpacked, and RGB24 formats supported for video mode
  - Serial configuration port (SCP) for the DSI\_PHY complex I/O and DSI PLL
  - Connection to the DSI\_PHY complex I/O through PPI
  - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
  - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
  - Supports selection between low-power state and HS mode between HS packet transfers
  - Generic data type (DT) support

---

**Note:** The DSI pins are multiplexed with LCD parallel outputs.

---

- Video encoder

- NTSC/PAL encoder outputs with the following standards:
  - NTSC-J, M
  - PAL-B, D, G, H, I
  - PAL-M
- CGMS-A as described in the CEA-608-x Standard.
- Input data interface compatible with the following protocols:
  - 24-bit input bus compatible with external sync
  - RGB 4:4:4
- Dual output data 10-bit interface for internal digital-to-analog converter (DAC) that supports:
  - Composite video (CVBS)
  - Separate video (S-video)
- TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
- Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
- Programmable horizontal sync, vertical timing, and waveforms
- Programmable subcarrier frequency and SCH
- Internal test pattern generation (color bar, flat field, color burst)
- 2x/4x oversampling
- Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

**CAUTION**

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

## 15.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

### 15.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

#### 15.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI protocol

The `DSS.DISPC_CONTROL[16:15]` `GPOUT[1:0]` bits control selection of the display subsystem modules (see [Table 15-1](#)).

**Table 15-1. I/O Pad Mode Selection**

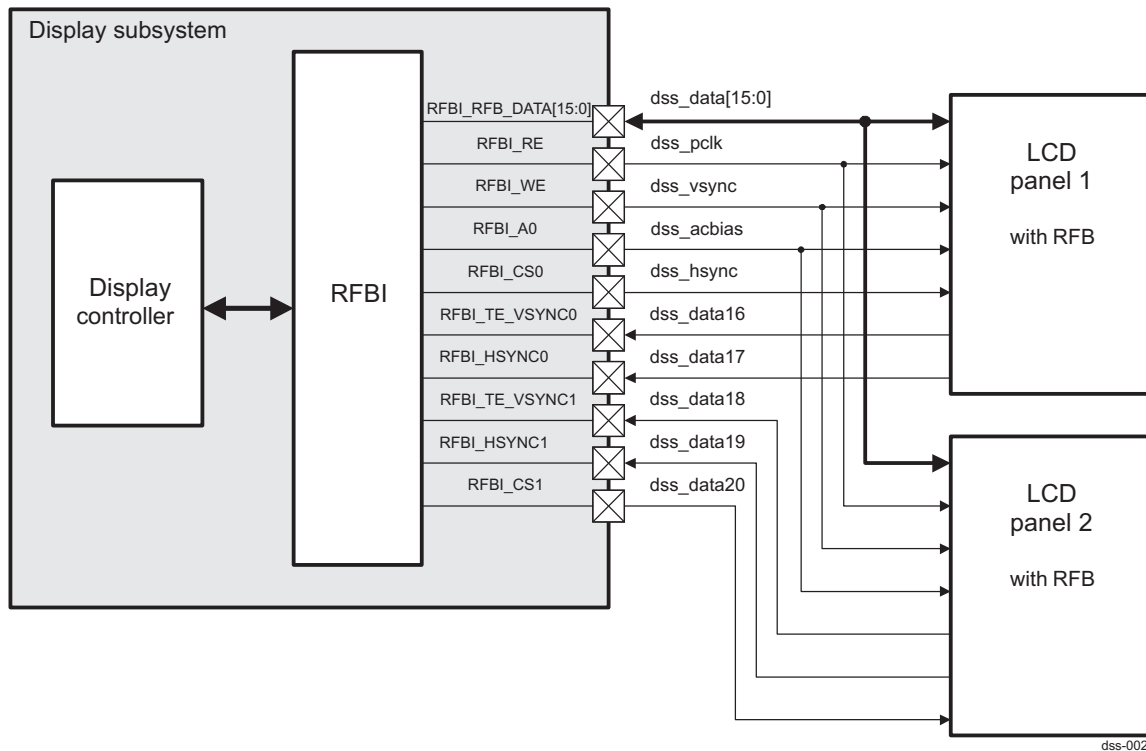

<code>DSS.DISPC_CONTROL[16]</code> <code>GPOUT1</code> Bit	<code>DSS.DISPC_CONTROL[15]</code> <code>GPOUT0</code> Bit	
	0	1
0	00 (reset)	01 (RFBI mode)
1	10 (invalid)	11 (bypass mode)

The RFB of the LCD panel is directly connected to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

### 15.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 15-2 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

**Figure 15-2. LCD Support Parallel Interface (RFBI Mode)**

**Note:** If the SDI is used, the second display device connected to RFB#1 is limited to 9-bit data.

Configure the DSS.RFBI\_CONTROL[3:2] CONFIGSELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 15-2 describes the interface signals to/from the LCD panel in RFBI mode.

**Table 15-2. LCD Interface Signals (RFBI Mode)**

Signal Name	Type <sup>(1)</sup>	Description
RFBI_RFB_DATA[15:0]	I/O	RFBI I/O data
RFBI_RE	O	Read access signal
RFBI_WE	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

<sup>(1)</sup> I = Input, O = Output

- **RFBI\_RFB\_DATA[15:0]:** The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.  
Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI\_RFB\_DATA is multiplexed at the chip-level boundary with `dss_data` [15:0].
- **RFBI\_RE:** This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_pclk`. The read is used to get status/data information from the LCD panel.
- **RFBI\_WE:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_vsync`.
- **RFBI\_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI\_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with `dss_acbias`.
- **RFBI\_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed ( $x = 0$  for LCD panel 1;  $x = 1$  for LCD panel 2). CS0 is multiplexed at the chip-level boundary with `dss_hsync`, and CS1 is multiplexed at the chip-level boundary with `dss_data`[20].
- **RFBI\_TE\_VSYNCx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI\_TE\_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.  
To select the trigger mode, configure the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE bit field (0x0: Internal trigger mode with the DSS.RFBI\_CONTROL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI\_TE\_VSYNCx, 0x2: External trigger mode with the RFBI\_TE\_VSYNCx, and RFBI\_HSYNCx signals with the programmable line counter).  
These signals are multiplexed at the chip-level boundary with `dss_data`[16] (RFBI\_TE\_VSYNC0) and `dss_data`[18] (RFBI\_TE\_VSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).
- **RFBI\_HSYNCx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI\_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with `dss_data`[17] (RFBI\_HSYNC0) and `dss_data`[19] (RFBI\_HSYNC1) (LCD panel 1:  $x = 0$ ; LCD panel 2:  $x = 1$ ).

#### 15.2.1.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 15-3](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

**Figure 15-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)**

dss-003

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_VSYNC\_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_HSYNC\_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI\_TE signal or use a bit field in the RFBI registers to start data capture.

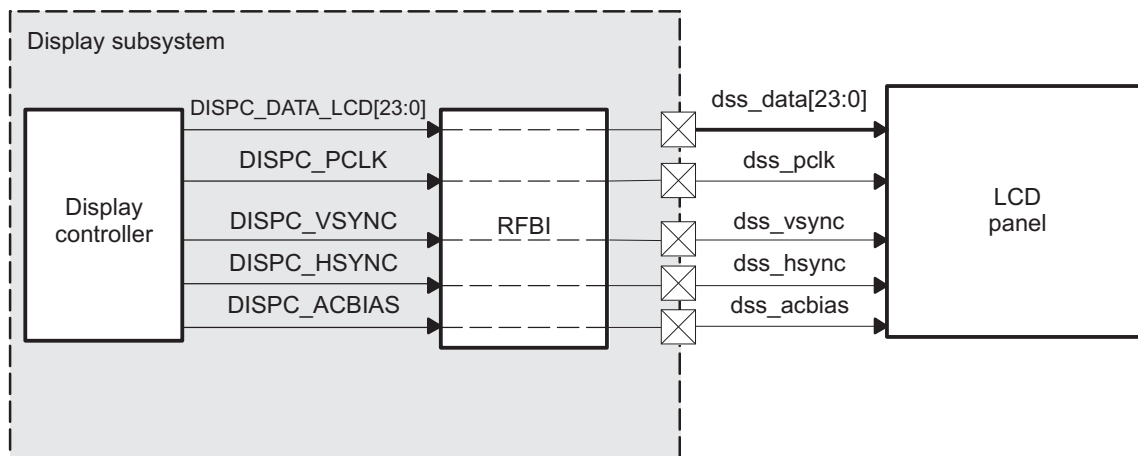

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

### 15.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 15-4 shows the LCD support parallel interface in bypass mode.

**Figure 15-4. LCD Support Parallel Interface (Bypass Mode)**

dss-004

**Note:** In bypass mode, the SDI and the parallel interface cannot be used at the same time.

Table 15-3 describes the interface signals to/from the LCD panel in bypass mode.

**Table 15-3. LCD Interface Signals (Bypass Mode)**

Signal Name	Type <sup>(1)</sup>	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- DISPC\_DATA\_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC\_DATA\_LCD is connected at the chip-level boundary with dss\_data[23:0].
- DISPC\_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss\_pclk.
- DISPC\_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame

clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with `dss_vsync` at the chip-level boundary.

- DISPC\_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with `dss_hsync`.
- DISPC\_ACBIAS: Uses the ac-bias signal from the display controller.
  - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
  - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with `dss_acbias`.

### 15.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 15-5 through Figure 15-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 15-4 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

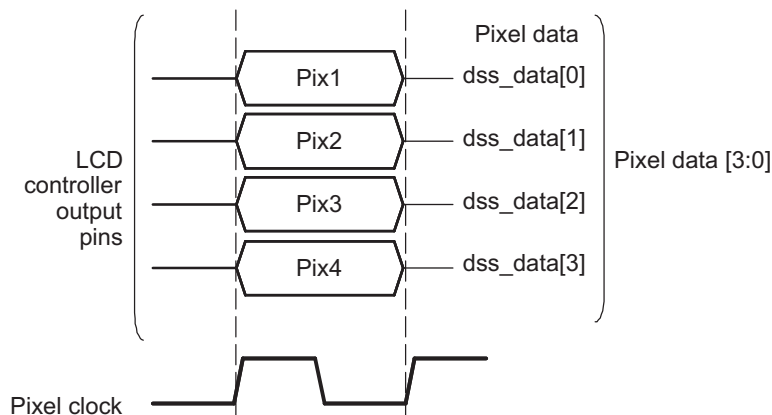

**Table 15-4. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type**

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

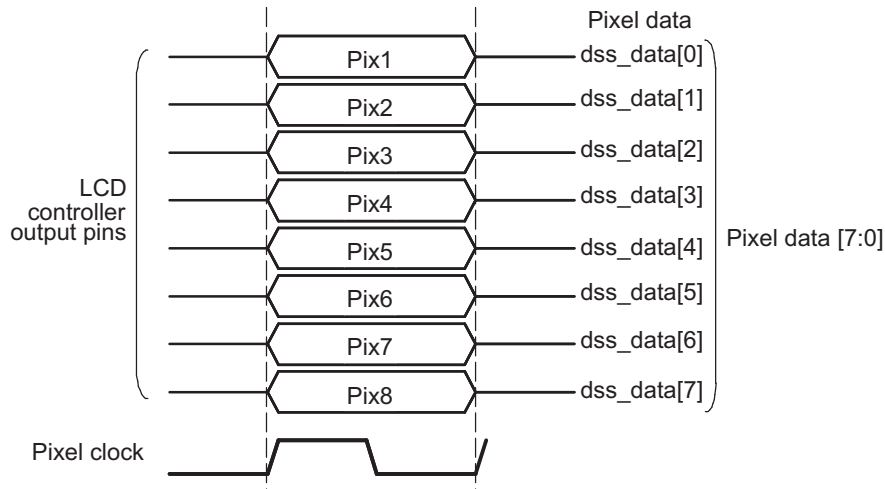

- Passive matrix technology, Monochrome mode  
Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

Figure 15-5 and Figure 15-6 show 4- and 8-bit monochrome displays, respectively.

**Figure 15-5. LCD Pixel Data Monochrome4 Passive Matrix**

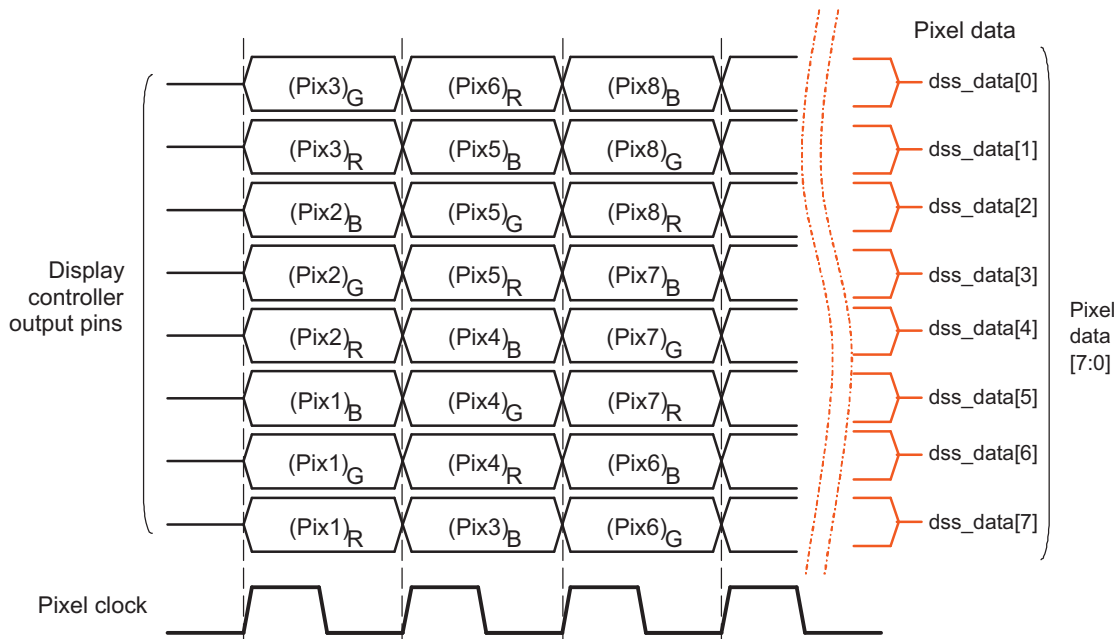

dss-005

**Figure 15-6. LCD Pixel Data Monochrome8 Passive Matrix**

dss-006

- Passive matrix technology, color mode  
Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).  
[Figure 15-7](#) shows an 8-bit color passive matrix display.

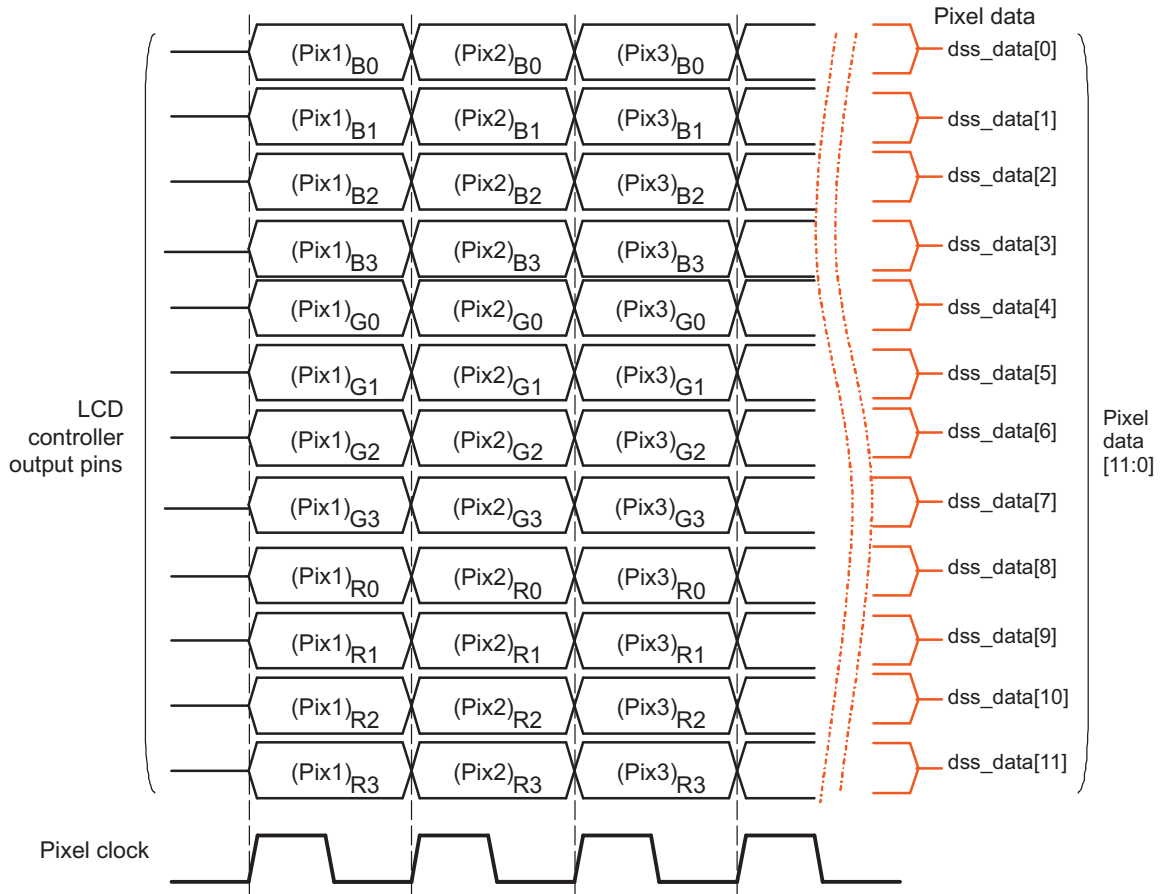

**Figure 15-7. LCD Pixel Data Color Passive Matrix**

dss-007

- Active matrix technology  
Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.  
[Figure 15-8](#) through [Figure 15-11](#) show 12-, 16-, 18-, and 24-active matrix displays, respectively.

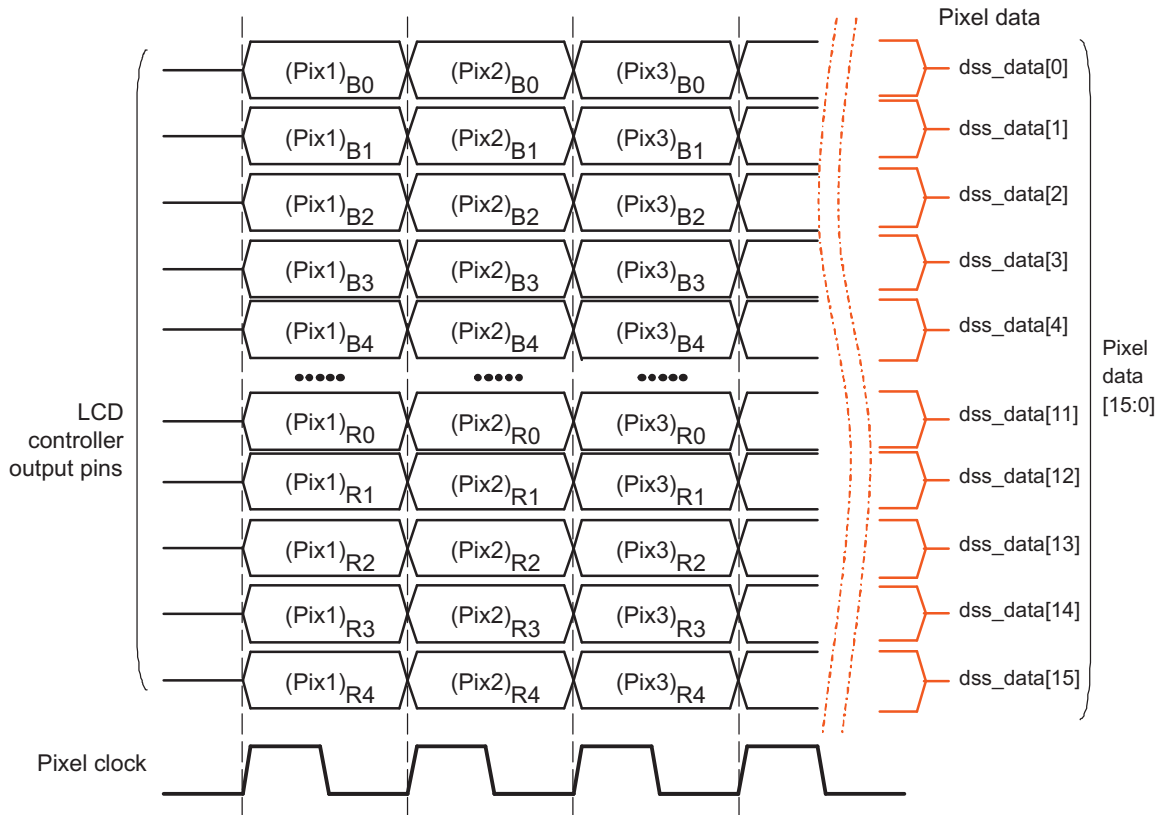

Figure 15-8. LCD Pixel Data Color12 Active Matrix

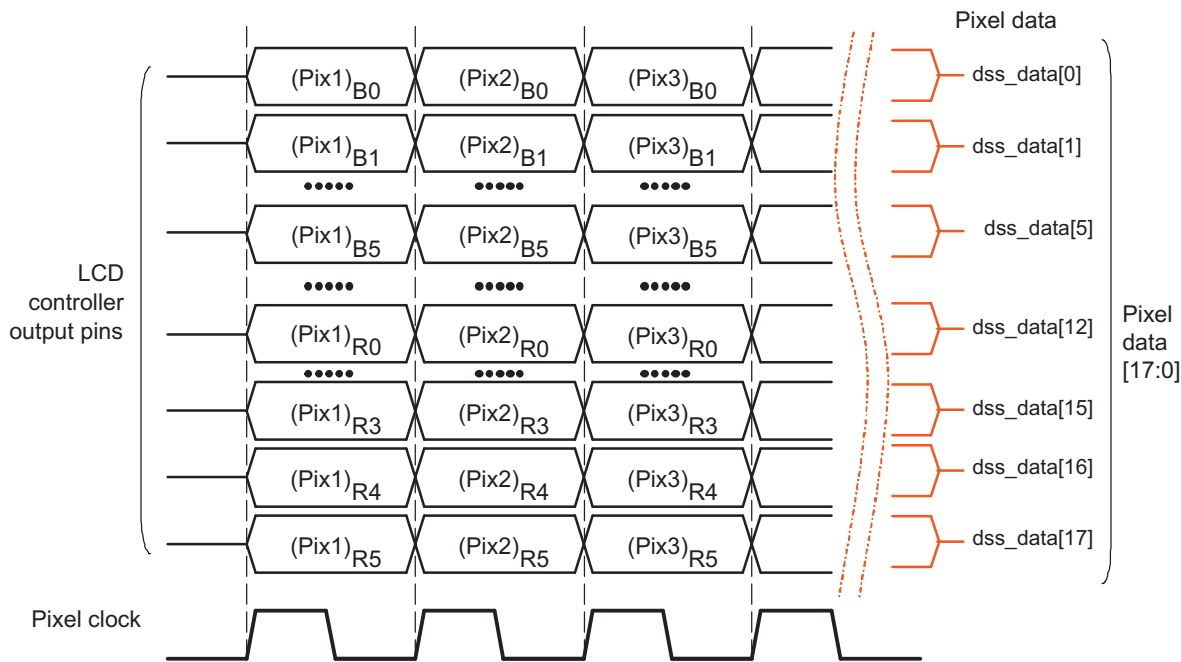

dss-008

Figure 15-11. LCD Pixel Data Color24 Active Matrix

dss-011

15.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
  - Stall signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

Figure 15-12. RFBI Data Stall Signal Diagram

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC\_CONFIG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC\_CONTROL[11] STALLMODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC\_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow can not occur for the pipelines associated with the LCD output in RFBI mode. Figure 15-13 details the RFBI data stall with FIFO handcheck mode activated.

**Figure 15-13. RFBI Data Stall Signal Diagram With Handcheck**

– RFBI timing diagrams

Table 15-5 lists the programmable timing fields. Figure 15-14 through Figure 15-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

**Table 15-5. Programmable Timing Fields in RFBI Mode**

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIME[3:0] CSONTIME (with I = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIME[9:4] CSOFFTIME (with I = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIME[5:0] WECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIME[13:10] WEONTIME (with I = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIME[19:14] WEOFFTIME (with I = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIME[11:6] RECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIME[23:20] REONTIME (with I = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIME[29:24] REOFFTIME (with I = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH (with I = 0 or 1)	The time when write cycle time or read cycle time completes

**Figure 15-14. Command Data Write**

dss-013

Figure 15-16. Read to Write and Write to Read

dss-014

- Timing diagrams in bypass mode

Figure 15-17 through Figure 15-32 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 15-6.

Table 15-6. Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1	Pixels per line (PPL)
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[31:20] HBP bit field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[19:8] HFP bit field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[7:0] HSW bit field value + 1	Horizontal synchronization pulse width

**Table 15-6. Programmable Fields in Bypass Mode (continued)**

Name	Register	Description
VBP	DSS.DISPC_TIMING_V[31:20] VBP bit field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[19:8] VFP bit field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[7:0] VSW bit field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK

### 15.2.1.2 SDI Serial Interface

In the serial interface, the modules in the display subsystem path are the display controller and the SDI with its associated PLL. The display controller provides the required control signals to interface the memory frame buffer (either SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA to read the data from the system memory.

The SDI module is an additional display output mode that facilitates the connection of displays over relatively few conductors.

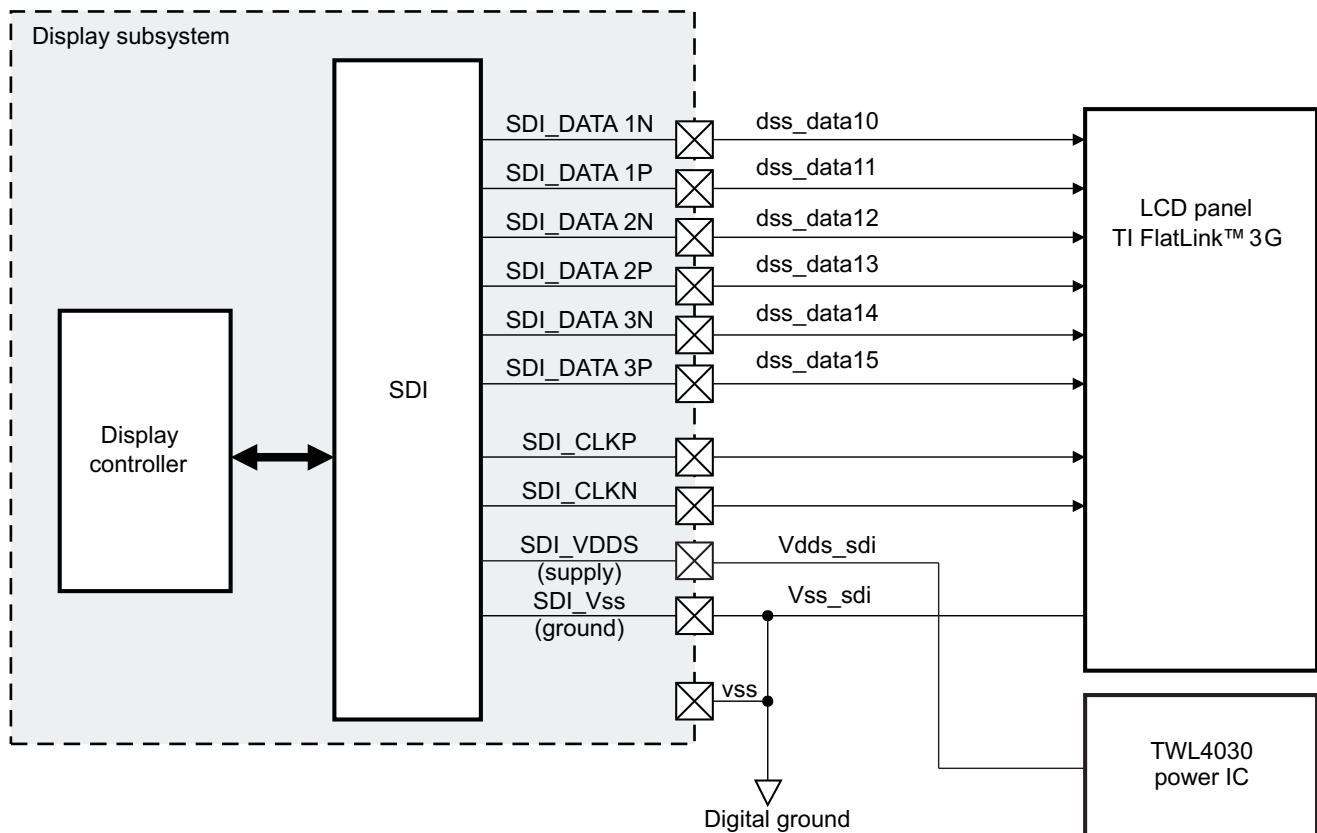

The SDI module implements the TI FlatLink3G protocol and converts the conventional parallel display signals (including pixel data) from the display controller to serial form. Texas Instruments provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver - SN65LVDS302 receiver for 3-data pair, SN65LVDS304 receiver for 2-data pair, and SN65LVDS306 receiver for 1-data pair.

The SDI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on 1 to 3 differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

**Note:** Only one 9-bit RFBI driven display can be run at the same time as the SDI.

Figure 15-33 shows a typical connection between the SDI module and a compliant panel display.

**Figure 15-33. Typical SDI Connection**

dss-031

**CAUTION**

When routing the PCB, ensure that the connections between the OMAP device and the LCD panel meet FlatLink3G specifications, which are available in the 27-bit serial display interface receiver data sheet.

**Notes:**

- The SDI pins are multiplexed in mode 1 with some LCD parallel pins. See [Chapter 7, System Control Module](#), for more details on pad multiplexing.
- The connection from the vss\_sdi pin of the device to the PCB digital ground must be as short as possible.
- The vdds\_sdi dedicated power supply is provided by a power IC. Texas Instruments provides a global solution with the OMAP device associated with a TWL4030 power IC.

[Table 15-7](#) describes the interface signals between the SDI module of the OMAP device and the LCD panel.

**Table 15-7. Interface Signals Between the SDI Module and LCD Panel**

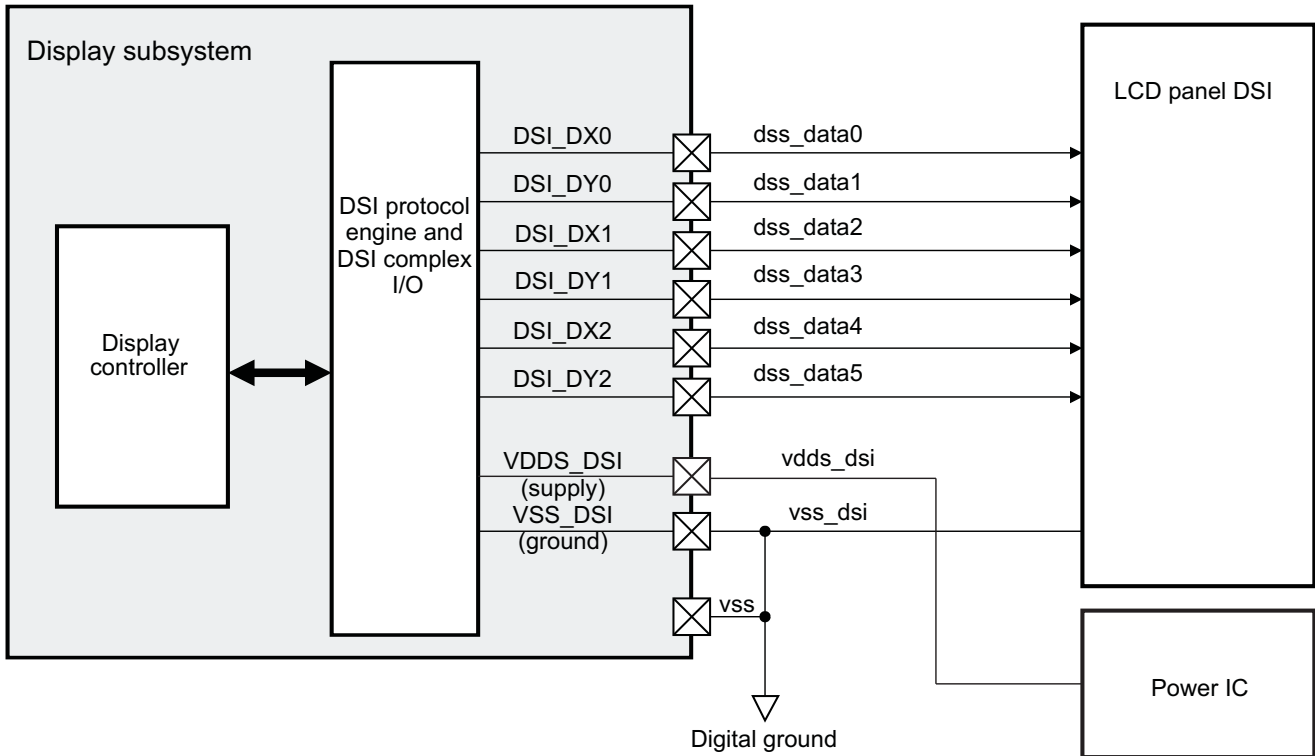

Signal Name	Type <sup>(1)</sup>	Description
SDI_DATA1N	O	First pair of differential data signals
SDI_DATA1P		
SDI_DATA2N	O	Second pair of differential data signals
SDI_DATA2P		
SDI_DATA3N	O	Third pair of differential data signals
SDI_DATA3P		
SDI_CLKN	O	Pair of differential clock signals
SDI_CLKP		
VDDS_SDI	PWR	Dedicated vdds power supply for SDI module
VSS_SDI	PWR	Dedicated vss ground for SDI module

15.2.1.3 DSI Serial Interface

Figure 15-34 shows a typical connection between the DSI modules and a compliant panel display.

Figure 15-34. Typical DSI Connection

dss-194

**Note:** The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See Chapter 7, System Control Module, for more details on pad multiplexing.

15.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section summarizes the MIPI DSI1.0 protocol and data format.

15.2.2.1 Physical Layer

Table 15-8 lists the DSI interface I/O.

Table 15-8. I/O Description for DSI Serial Interface

Signal Name	I/O <sup>(1)</sup>	Description	Value at Reset
dsi_dx0	line 1	I/O	Serial data/clock input/output
dsi_dy0			N/A
dsi_dx1	line 2	I/O	Serial data/clock input/output
dsi_dy1			N/A
dsi_dx2	line 3	I/O	Serial data/clock input/output
dsi_dy2			N/A

<sup>(1)</sup> I/O = Input/Output

---

**Note:** Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

---

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

### 15.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode; otherwise, the clock is extracted from the received data in low-speed mode. The data is transmitted byte-wise least significant bit (LSB) first.
- The clock signal carries the DDR clock signal in high speed transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI\_PHY into bytes.

[Table 15-9](#) details all the DSI lanes configuration.

**Table 15-9. DSI Lane Configuration**

DSI DSI_PHY Lane Configuration	Data/Clock Lane Position			Description
	1	2	3	
Mode CLK + DATA1	CLK	DATA1	Not used	Single data lane
	CLK	Not used	DATA1	
	DATA1	CLK	Not used	
	Not used	CLK	DATA1	
	DATA1	Not used	CLK	
	Not used	DATA1	CLK	
Mode CLK + DATA1 + DATA2	CLK	DATA1	DATA2	Two data lanes
	CLK	DATA2	DATA1	
	DATA1	CLK	DATA2	
	DATA2	CLK	DATA1	
	DATA1	DATA2	CLK	
	DATA2	DATA1	CLK	

**Notes:**

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through programming of the DSS.DSI\_COMPLEXIO\_CFG1 register. The CLOCK\_POSITION and CLOCK\_POL bit fields configure which lane transmits the clock and define its polarity. Four bit fields (DATA1\_POSITION, DATA1\_POL, DATA2\_POSITION, and DATA2\_POL) configure the data lanes and their polarity. The DATA2\_POSITION bit field can be set to 0; in this case, only the data lane defined in the DATA1\_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) should not be changed while DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE bit is set to 1. For the hardware to recognize a new configuration of the complex I/O (done in DSS.DSI\_COMPLEXIO\_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI\_CTRL[0] IF\_EN bit to 1, next reset the DSS.DSI\_CTRL[0] IF\_EN to 0, then set DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE to 1, and finally, set again the DSS.DSI\_CTRL[0] IF\_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is undetermined.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bidirectional

### 15.2.2.1.2 ULPS

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the DSI module.
- For data lane 1, no BTA should have been sent. The DSI module should have control of the bus.

The control of each lane is independently controlled by the DSS.DSI\_COMPLEXIO\_CFG2 register.

### 15.2.2.2 Video Port (VP) Interface

**Note:** The signals described in this section are internal and not bounded outside the device. This section aims at helping software users understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

Table 15-10 summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data streams. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on the rising or falling edge of the pixel clock (VP\_PCLK).

**Table 15-10. Video Interface for DSI Protocol Engine**

Signal Name	Type <sup>(1)</sup>	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP_CLK.
VP_DE	I	Data enable
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).

<sup>(1)</sup> I = Input, O = Output

**Table 15-10. Video Interface for DSI Protocol Engine (continued)**

Signal Name	Type <sup>(1)</sup>	Description
VP_CLK	I	Display controller internal clock. It is a free-running clock. The VP_CLK is a divided clock from VP_PCLK.

**Notes:**

- The polarities of VP\_HSYNC and VP\_VSYNC are programmable by setting the DSS.DSI\_CTRL register.
- The maximum frequency for VP\_CLK is 173 MHz at nominal voltage, and 96 MHz at low voltage.
- Clocks VP\_CLK and VP\_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH bit field.
- VP\_DE is connected to the dss\_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC\_POL\_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, can not be used. Only the transparency burst mode is supported.

**Note:** The DSS.DSI\_CTRL[13:12] LINE\_BUFFER bit field defines the number of lines to be used for transferring data from the video port to the DSI link.

**15.2.2.2.1 Video Port Used for Video Mode**

If the video port is used for video mode, the VP\_STALL is not used. Table 15-11 lists the active signals on the video port.

**Table 15-11. Video Interface in the Context of Video Mode**

Signal Name	Type <sup>(1)</sup>	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	Pixel clock.
VP_DE	I	Data enable
VP_CLK	I	It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage, and 96 MHz at low voltage.

<sup>(1)</sup> I = Input, O = Output

Three video modes are available:

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The VP\_CLK must match the DSI high-speed (HS) clock to get the exact same throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide such configuration).
- One line buffer:
  - The data can be transferred as described in the *No line buffer* configuration.
  - The data are first stored in the line buffer; once all the data for one line are received, the DSI protocol engine sends the whole line. All the synchronization packets occur at the same time as the previous mode. Only the time when RGB packets are sent is delayed.
- Two line buffers:

- 
- The data can be transferred as described in the *One line buffer* configuration.
  - One line is stored when the second line is output on the DSI port. It allows burst capability. The synchronization packets are not modified when bursting the RGB packets. While receiving the first line of the frame, there is no RGB packets sent because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers.

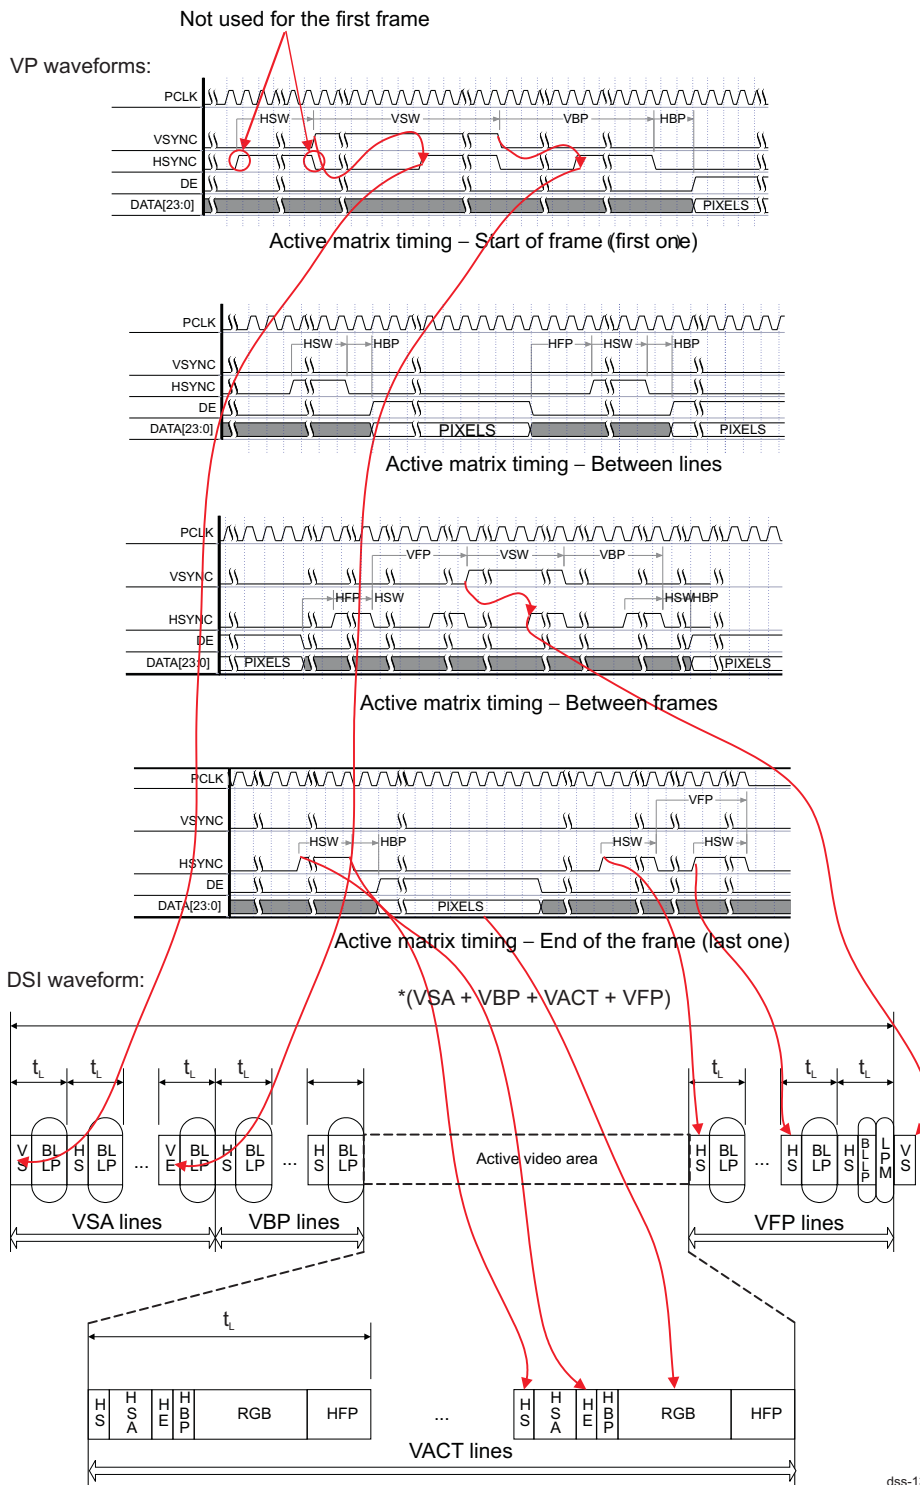

---

**Note:** If more active lines are received on the video port than the number defined in the DSS.DSI\_VM\_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

---

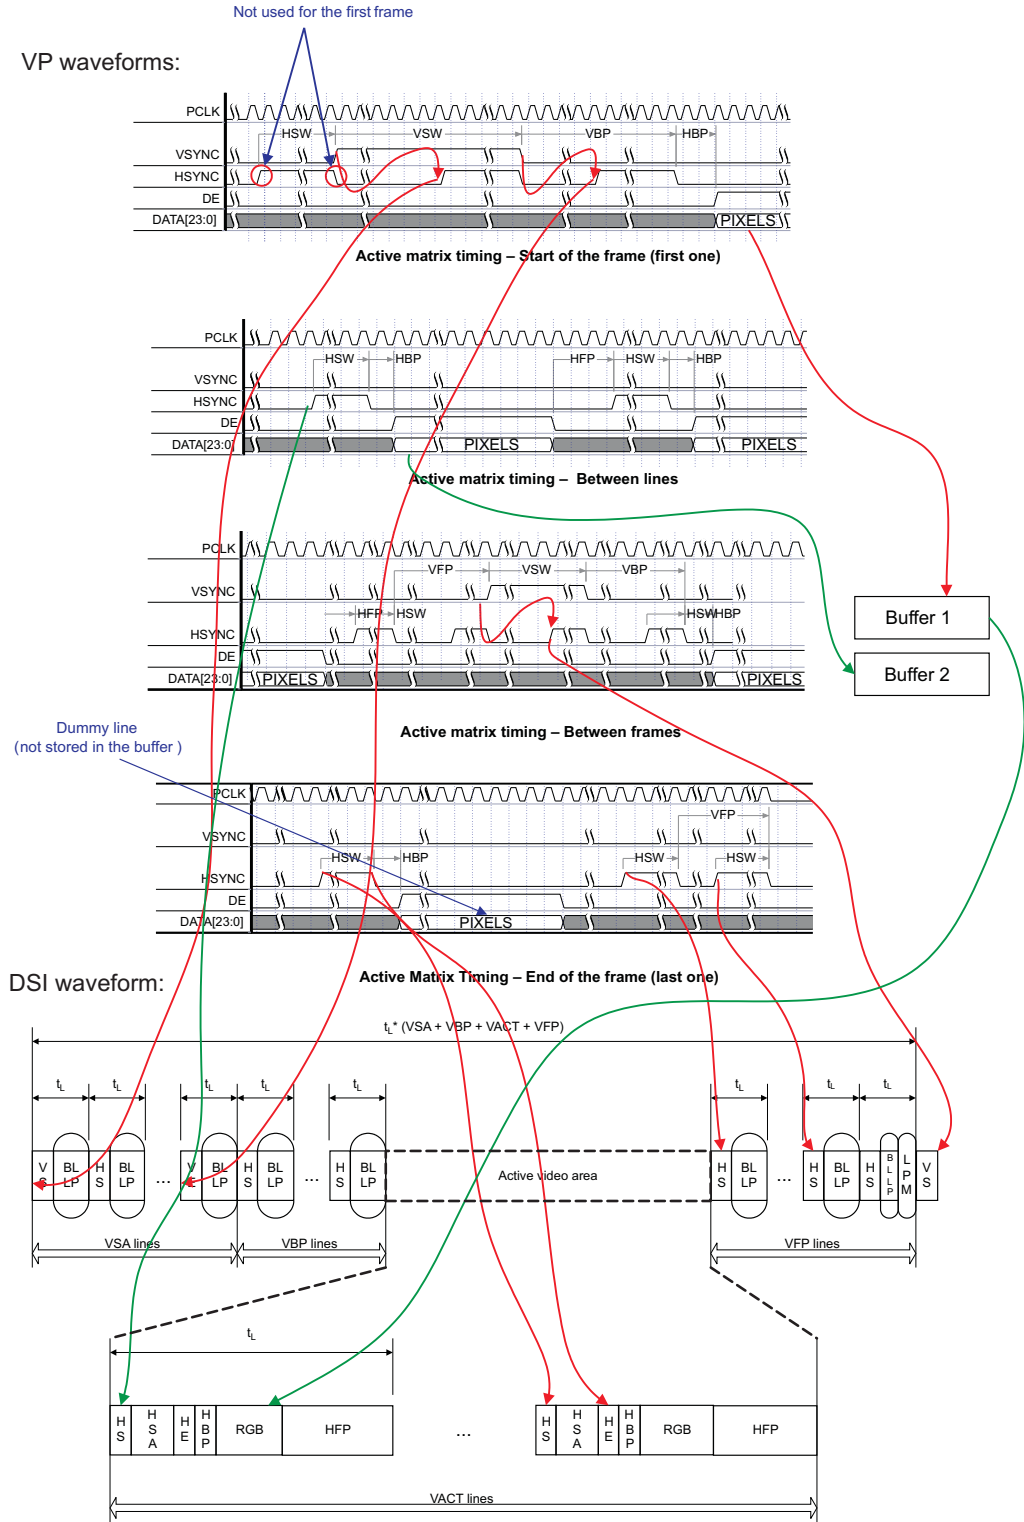

Figure 15-35, Figure 15-36, and Figure 15-37 show these three video modes.

**Figure 15-35. DSI Video Mode Without Burst (No-Line Buffer)**

**Figure 15-37. DSI Video Mode With Burst (Two-Line Buffers)**

dss-138

**Note:** In [Figure 15-35](#), [Figure 15-36](#), and [Figure 15-37](#):

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different from 0.
- The software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible
  - The lane remains in ULPS, and the [DSI\\_CTRL\[20\]](#) BLANKING\_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the [DSI\\_CTRL\[20\]](#) BLANKING\_MODE bit set to 0x1; the number of sent bytes is determined by the [DSI\\_VM\\_TIMING6\[15:0\]](#) BL\_LP\_INTERLEAVING bit field.

If the signal VP\_DE is not asserted during enough VP\_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP\_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP\_DE signal is asserted for too many VP\_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS must check that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync should be generated and the interface must be disabled (DSS.DSI\_CTRL[0] IF\_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI\_VM\_TIMING2[27:24] WINDOW\_SYNC bit field.

#### 15.2.2.2 Video Port Used on Command Mode

If the video port is used for command mode, the VP\_HSYNC, VP\_VSYNC, and VP\_DE signals are not used. [Table 15-12](#) describes the active signals on the video port.

**Table 15-12. Video Interface in the Context of Command Mode**

Signal Name	Type <sup>(1)</sup>	Description
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	One pulse is generated every time new data is output on the data bus
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).
VP_CLK	I	Display controller internal clock: It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage and 96 MHz at low voltage.

<sup>(1)</sup> I = Input, O = Output

**Note:** The stall signal must be deasserted to receive pixels and asserted to stop receiving pixels.

[Figure 15-38](#) and [Figure 15-39](#) show the VP\_STALL signal assertion and deassertion on rising and falling edges, respectively.

**Note:** In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 1.

**Figure 15-38. Stall Timing With Pixel on Rising Edge**

dss-187

**Figure 15-39. Stall Timing With Pixel on Falling Edge**

dss-188

To stop the transfer, the VP\_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP\_PCLK through registers in the display controller module. The case with data output on falling edge of VP\_PCLK is supported by the DSI protocol engine.

The VP\_PCLK clock is generated from VP\_CLK; these two clocks are balanced. Assertion and deassertion of VP\_PCLK is done on the rising edge of VP\_CLK. The width of the VP\_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC\_DIVISOR[7:0] PCD bit field). In the DSI protocol engine, the information is defined in the DSS.DSI\_CTRL[4] VP\_CLK\_RATIO bit and should be aligned with the display controller configuration.

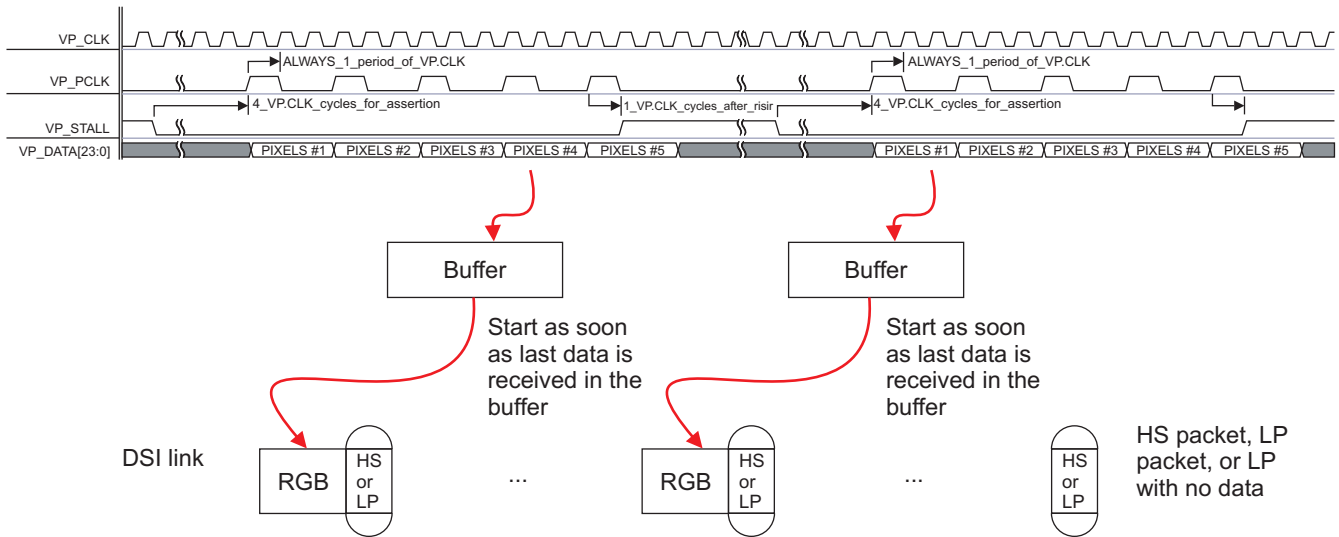

Deassertion of the VP\_STALL signal should occur at least 4 VP\_CLK cycles before assertion of VP\_PCLK. Assertion of VP\_STALL should occur one cycle VP\_CLK after deassertion of VP\_PCLK for the last pixel to be transferred. The VP\_CLK clock is generated by the display controller under software control. It can be kept running between assertion and deassertion of VP\_STALL.

The word count (WC) defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register for the virtual channel (VC) associated with the video port, indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and size of the line buffer). The total size defined in the WC of the header register can not exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSS.DSI\_CTRL[7:6] VP\_DATA\_BUS\_WIDTH bit field.

Figure 15-40 shows the data flow in command mode using the video port.

Figure 15-40. Data Flow in Command Mode Using the Video Port

dss-139

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent.
- Two line buffers: The two lines are used if the word count defined in the `DSS.DSI_VCN_LONG_PACKET_HEADER` register is bigger than the line size; otherwise, one line buffer is used.

---

**Note:** In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

---

The packets can be sent using high-speed or low-speed.

---

**Note:** The DCS command in the payload can be inserted automatically using the `DSI_CTRL[24]` `DCS_CMD_ENABLE` bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

---

### 15.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the `VP_HS` signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

---

**Note:** The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They should be sent according to the video port timings.

---

### 15.2.2.3 Multilane Layer

Peripherals do not typically have high bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems should only use Lane 1 in LP mode for returning data from a peripheral to the host processor.

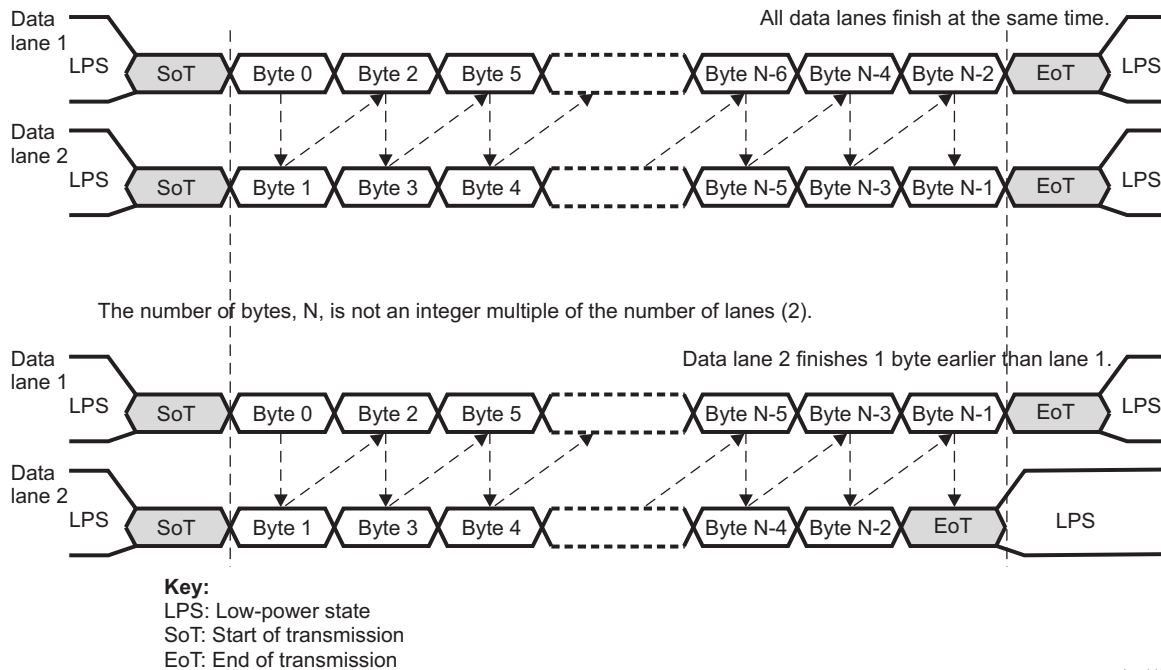

#### 15.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its *valid data* signal into all lanes for which there is no further data. Although all lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

#### 15.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). Figure 15-41 and Figure 15-42 show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using high-speed mode (HS). In low-power mode (LP), only one data lane is used (Lane 1).

**Figure 15-41. Two Data Lane Configuration**

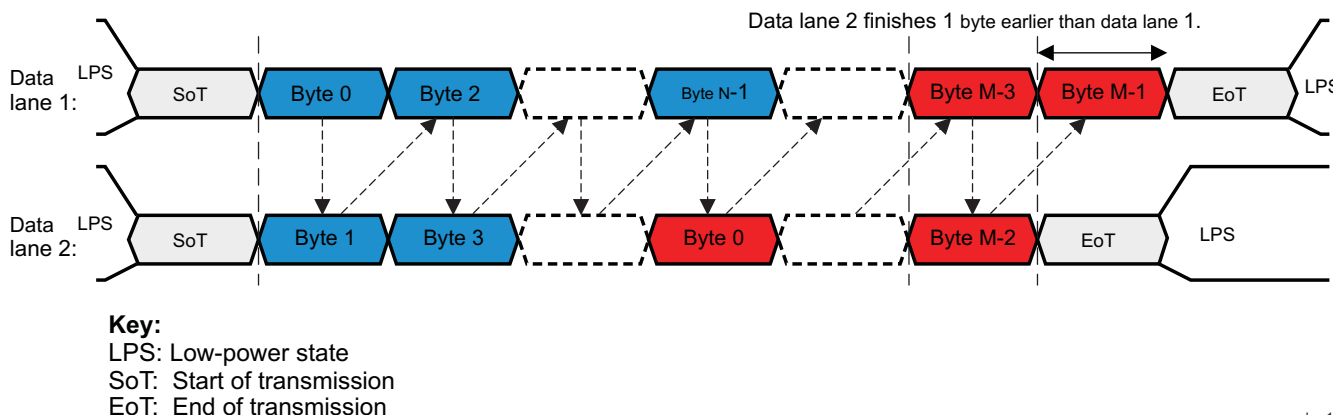

**Figure 15-42. One Data Lane Configuration**

In case of back-to-back packets, the byte stream is considered as a single packet by the splitter module. Figure 15-43 shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

Figure 15-43. Two Packets Using Two-Data Lane Configuration (Example)

dss-142

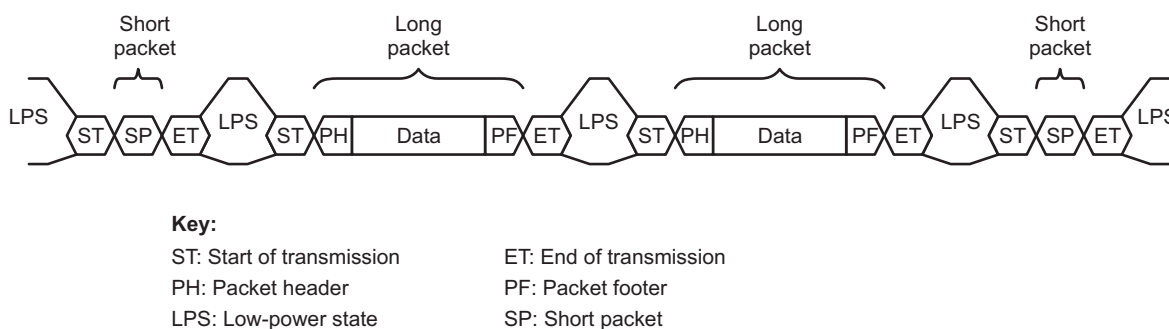

### 15.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using high-speed or low-speed mode. LLP is selected through DSI registers. The features of the DSI protocol layer are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 15-44 shows the protocol layer with short and long packets.

Figure 15-44. Protocol Layer With Short and Long Packets

dss-143

#### 15.2.2.4.1 Short Packet

Figure 15-45 shows the structure of the short packet. A short packet should contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC; a packet footer should not be present. Short packets should be four bytes in length. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

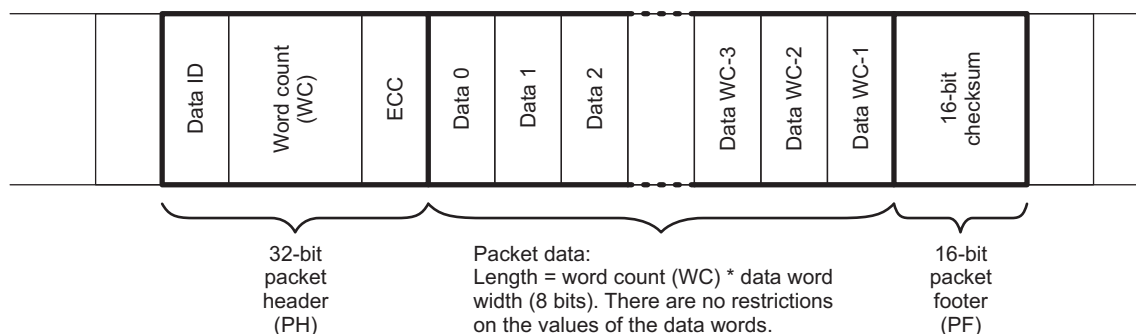

**Figure 15-45. Short Packet Structure**

dss-144

**Note:** The short packets can be sent in low-power mode or in high-speed mode.

#### 15.2.2.4.2 Long Packet

Figure 15-46 shows the structure of the low-level protocol long packet. A long packet must consist of three elements: A 32-bit packet header (PH), an application-specific data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header is further composed of three elements: An 8-bit data identifier, a 16-bit word count, and 8-bit ECC. The packet footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

**Figure 15-46. Long Packet Structure**

dss-145

- The data identifier defines the VC for the data and the DT for the application-specific payload data.
- The word count defines the number of bytes in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer should be included in the word count.
- The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes the data identifier and the word count fields.

After the end of the packet header, the receiver reads the next word count \* bytes of the data payload. There are no limitations on the value of a data word within the data payload block, that is, no embedded codes are used. Once the receiver has read the data payload, it reads the checksum in the packet footer. The host processor should always calculate and transmit a checksum in the packet footer. Peripherals are not required to calculate a checksum. Also note the special case of zero-byte data payload: If the payload has length 0, then the checksum calculation results in (0xFFFF). If the checksum is not calculated, the packet footer should consist of two bytes of all zeros (0x0000). In the generic case, the length of the data payload should be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, that is, multiple of four bytes. Each byte is transmitted LSB first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multibyte elements such as word count and checksum should be transmitted least-significant byte first.

**Note:** The long packets can be sent in low-power mode or in high-speed mode.

### 15.2.2.4.3 Data Identifier

The data identifier byte contains the virtual VC ID value and the DT value as illustrated in Figure 15-47. The VC ID is contained in the two MS bits of the data identifier byte. The DT value is contained in the six LSBs of the data identifier byte. DI[7:6]: These two bits identify the data as directed to one of four VCs. DI[5:0]: These six bits specify the DT.

Figure 15-47. Data Identifier Structure

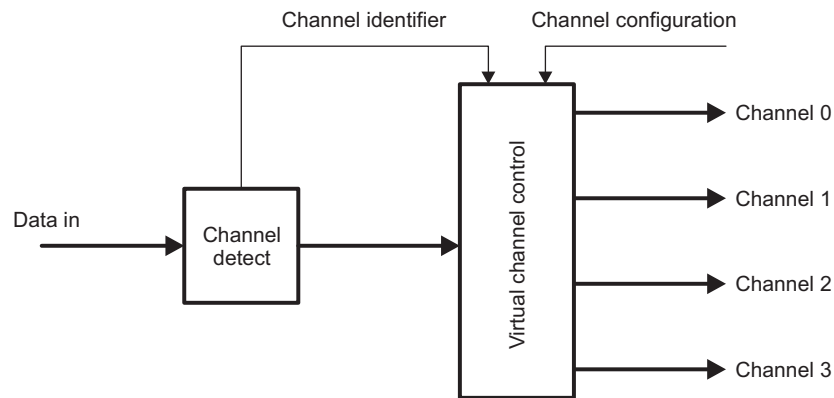

dss-146

### 15.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that each packet sent in a single transmission have its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER and DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers for short and long packets, respectively. It should not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 15-48 shows the VC controller.

Figure 15-48. Virtual Channel Controller

dss-147

### 15.2.2.4.5 Data Type Field DT[5:0]

The DT field specifies whether the packet is a long or short packet type and the packet format. The DT field, along with the word count field for long packets, informs the receiver on how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start/end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

#### 15.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. [Table 15-13](#) summarizes the pixel formats supported by the DSI interface in video mode.

**Table 15-13. Pixel Data Format in Video Mode**

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

#### 15.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to automatically generate the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transitions from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port prior to the first VSYNC should be ignored. Since the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should be no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 15-14](#) summarizes the 6-bit DT synchronization code values.

**Table 15-14. Synchronization Codes**

Synchronization Code	Value	Comments
V sync start code (VSSC)	0x1	Optional
V sync end code (VSEC)	0x11	Optional
H sync start code (HSSC)	0x21	Optional
H sync end code (HSEC)	0x31	Optional

#### 15.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long blanking packets are sent to the display. The DSS.DSI\_VM\_TIMING<sub>i</sub> (I between 1 and 7) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

Table 15-15 defines the short packet values for the synchronization packets:

**Table 15-15. Sync Short Packet Values**

Virtual Channel ID	Sync Code	Header (1st Byte)	Header (2nd Byte): Data Field LSB	Header (3rd Byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See note following this table
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

**Notes:**

- If the ECC is enabled by setting the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit to 1 for the VC in video mode, the check-sum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, since the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The link [lane(s) and clock separately] can be put in ULPS mode. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and  $t_L$  are defined in the DSS.DSI\_VM\_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and  $t_L$  are defined using the byte clock unit (TxByteClkHS) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking into account the 4-byte header and the 2-byte check sum).

The configuration of the display controller timing generator must be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period can not be used for sending any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC, or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC, by another VC, by trigger (BTA

for example), or by extra LP NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 15-49 and Figure 15-50 show a nonburst transfer in DSI video mode with, and without VE and HE, respectively.

**Figure 15-49. DSI Video Mode: Nonburst Transfer With VE and HE**

dss-148

Figure 15-50. DSI Video Mode: Nonburst Transfer Without VE and HE

dss-149

**Note:** HSA timing is not used and does not have to be programmed when HE short packet is not generated.

**Figure 15-51. DSI Video Mode: Burst Transfer Without VE and HE**

dss-150

**Note:** HSA timing is not used and does not have to be programmed when HE short packet is not generated.

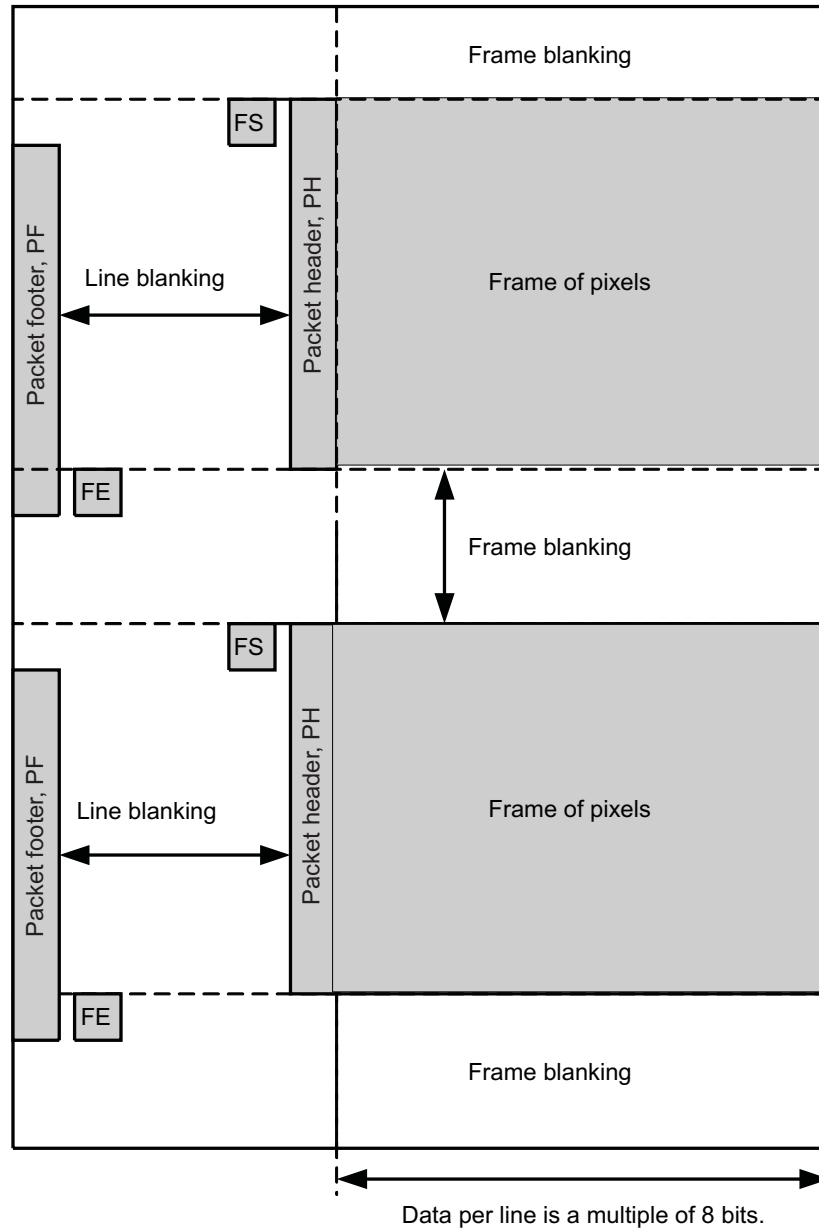

In [Figure 15-50](#) and [Figure 15-51](#), if HSync end short packet is not generated (HSA does not exist), HBP should be other than 0.

15.2.2.4.9 Frame Structures

#### 15.2.2.4.10 Virtual Channels

The DSI protocol layer transports VCs. The purpose of VCs is to separate different data flows, which are interleaved in a same data stream. Each VC is identified by a unique channel identification number in the packet header. The channel identification number is encoded in 2-bits. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent VCs: Up to 4. [Table 15-16](#) summarizes the VC values used for each channel.

**Table 15-16. Virtual Channel Values**

Virtual Channel Number	Value
Virtual channel 0	0x0
Virtual channel 1	0x1
Virtual channel 2	0x2
Virtual channel 3	0x3

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to route the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

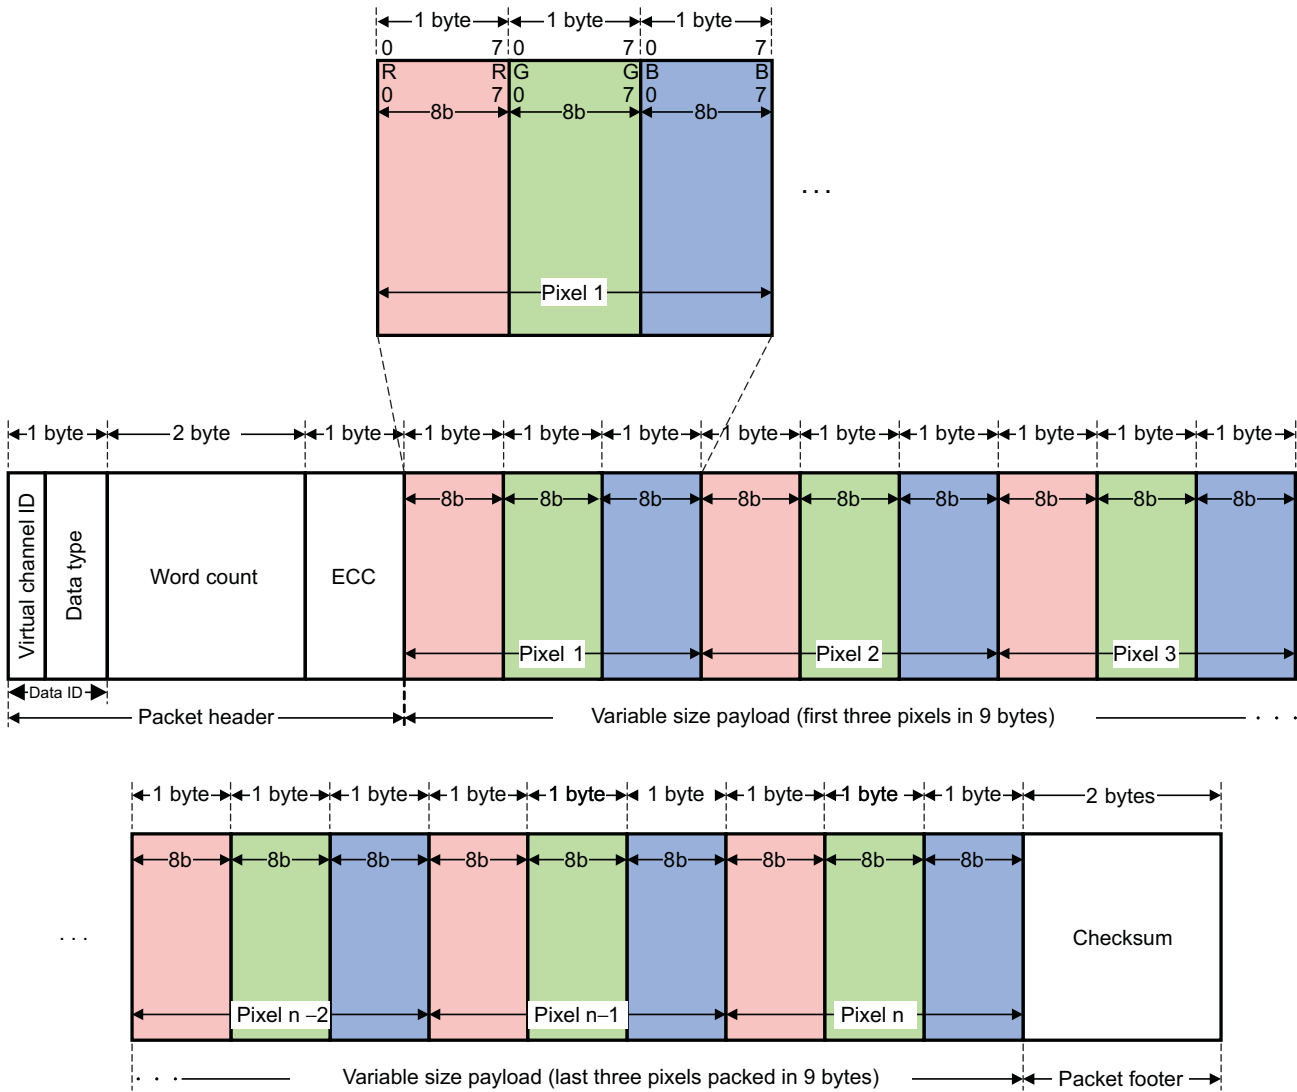

#### 15.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in video mode are transmitted over the serial interface. For pixel formats in command mode. The DSI protocol engine can cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

15.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

Figure 15-55 shows the RGB888 format.

Figure 15-55. 24 Bits per Pixel RGB Color Format, Long Packet

dss-154

Packed pixel stream 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (8 bits), green (8 bits), and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

### 15.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 15-56 details the RGB666 format.

Figure 15-56. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

dss-155

In the 18-bit pixel loosely-packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (6 bits), green (6 bits), and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

15.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 15-57 details the RGB666\_PACKED format.

Figure 15-57. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet

dss-156

Packed pixel stream 18-bit format (packed) is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is red (6 bits), green (6 bits), and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

#### 15.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 15-58 details the RGB565 format.

Figure 15-58. 16 Bits per Pixel RGB Color Format, Long Packet

dss-157

Packed pixel stream 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the *green* component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

### 15.2.3 LCD Output With TI FlatLink3G Data Format for the SDI Module

The parallel-to-serial conversion of the 24-BPP pixel data depends on the number of data channels in use.

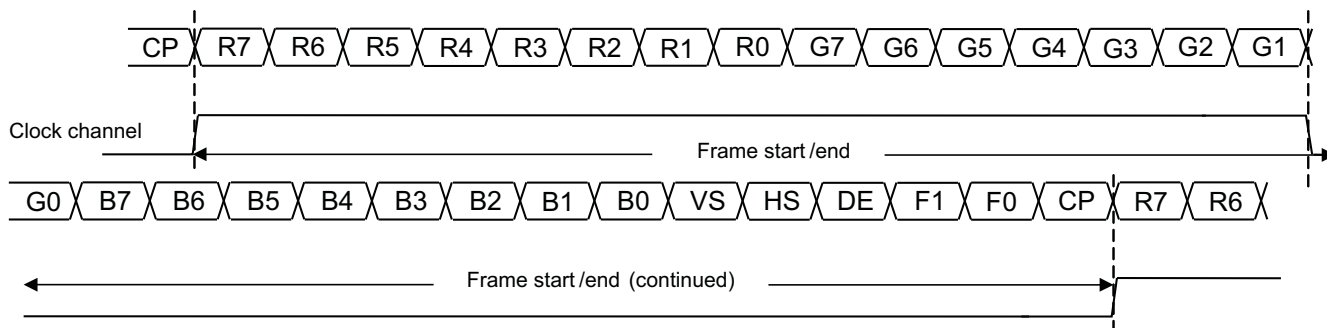

Figure 15-59 through Figure 15-61 summarize the pixel order for each data format of the TI FlatLink3G LCD panel.

The following apply to Figure 15-59 through Figure 15-61:

- VS: Vertical synchronization
- HS: Horizontal synchronizations
- DE: Data enable
- CP: Pixel parity. Parity of the whole 30-bit data is odd
- F1, F0: Reserved bits for the TI FlatLink3G protocol
- Clock channel: Differential clock signal between SDI\_CLKP and SDI\_CLKN

Figure 15-59. 24 Bits Per Pixel With One Data Channel

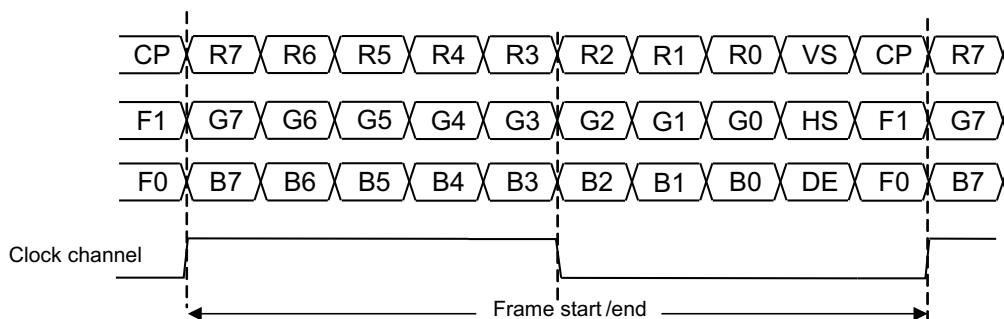

dss-032

Figure 15-60. 24 Bits Per Pixel With Two Data Channels

dss-033

Figure 15-61. 24 Bits Per Pixel With Three Data Channels

dss-034

**Note:** The range of the data rates permitted is 120 Mbps per pair minimum (4 MHz pixel clock, one data pair) to 650 Mbps per pair maximum (65 MHz pixel clock, three data pairs).

### 15.2.4 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Dual 10-bit DAC with video amplifiers

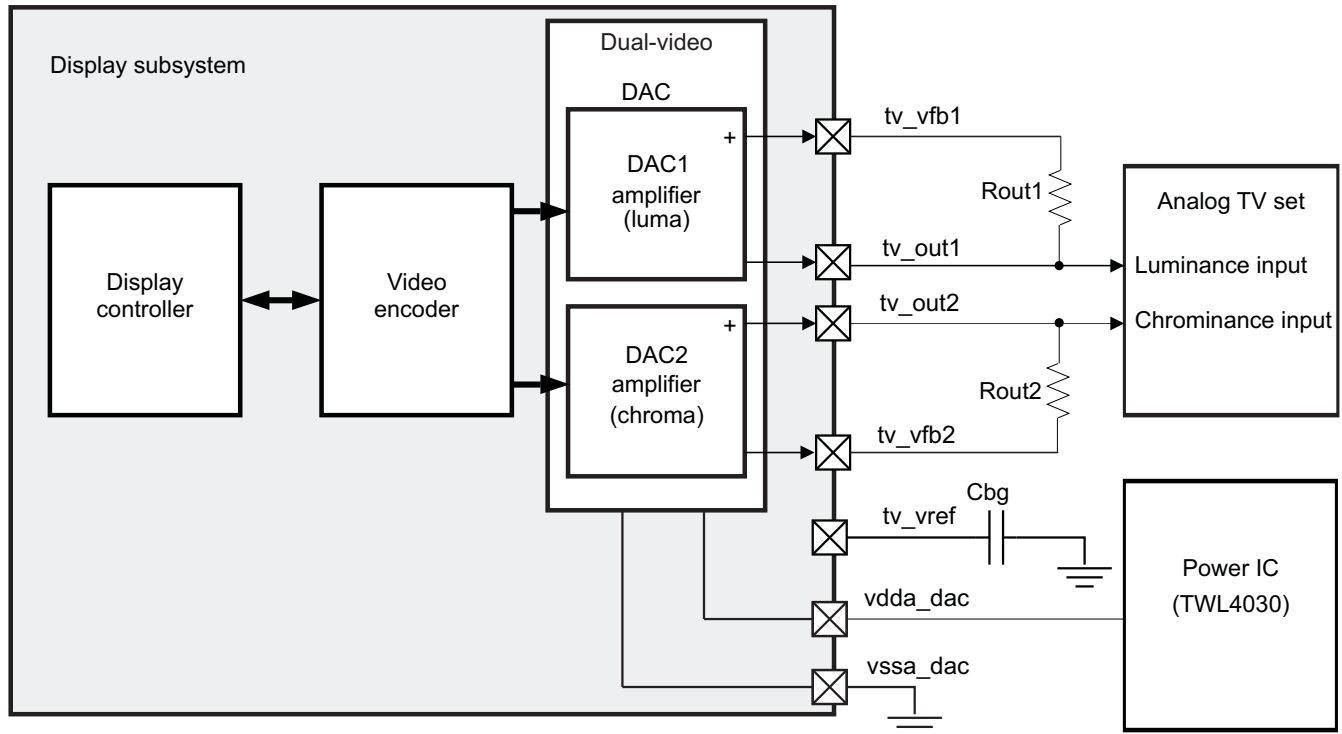

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and a 2-channel video digital-to-analog converter (DAC) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, active Video (AVID), and field ID (FID).

Figure 15-62 is a block diagram of the TV display interface (s-video mode).

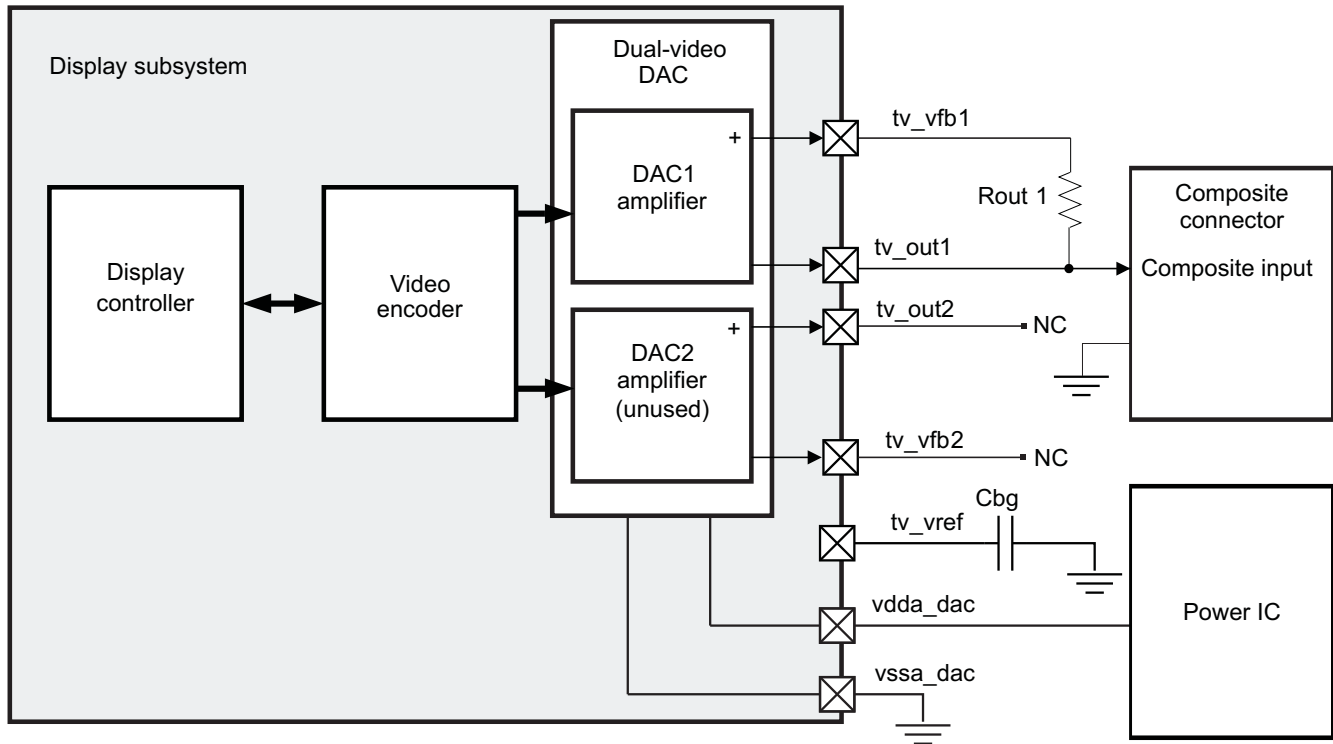

**Figure 15-62. TV Display Interface (s-video mode)**

dss-035

Figure 15-63 is a block diagram of the TV display interface (composite mode).

Figure 15-63. TV Display Interface (Composite Mode)

dss-191

**Note:** In composite video mode, the video DAC2 chroma output must be disabled by setting the `DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE` bit to 0.

Table 15-17 describes the interface signals to/from the TV set for TV display support.

Table 15-17. TV Display Interface Pins

Pin Name	Type <sup>(1)</sup>	Description
tv_out1	O	Analog luma or composite video output. An external resistor is connected between this node and the tv_vfb1 pin. The nominal value of Rout1 is 1650 Ω. Note that this is the output node that drives the load (75 Ω).
tv_out2	O	Analog chroma video output. An external resistor is connected between this node and the tv_vfb2 pin. The nominal value of Rout2 is 1650 Ω. This is the output node that drives the load (75 Ω).
tv_vfb1	O	Amplifier feedback node. An external resistor is connected between this node and tv_out1. The nominal value of Rout1 is 1650 Ω.
tv_vfb2	O	Amplifier feedback node. An external resistor is connected between this node and tv_out2. The nominal value of Rout2 is 1650 Ω.
tv_vref	O	Reference output voltage from internal bandgap. A decoupling capacitor must be connected for optimum performance. tv_vref is generated internally to the OMAP device.
vdda_dac	Power	Analog supply voltage for the dual video DAC
vssa_dac	Power	Analog ground for the dual video DAC

(1) O = Output, Power = Power pin

**CAUTION**

- tv\_out1 and tv\_out2 are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. tv\_vfb1 and tv\_vfb2 pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins should be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the tv\_vfb1/tv\_vfb2 and TV OUT pins (tv\_out1 and tv\_out2). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the OMAP device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75  $\Omega$  starting from the closest possible place to the OMAP device pin output. For typical values of Rout1, Rout2, Cout, and Cbg, see the device data manual.
- If the TV output is not used, the analog pins tv\_ref and vdda\_dac must be grounded. The tv\_out1, tv\_out2, tv\_vfb1, and tv\_vfb2 pins can be grounded or left unconnected. To avoid current leakage, the following bits must be set to 0:
  - DSS.DSS\_CONTROL[5] DAC\_POWERDN\_BGZ
  - DSS.VENC\_OUTPUT\_CONTROL[2:0]
  - PRM.CM\_FCLKEN\_DSS[2] EN\_TV
  - CONTROL.CONTROL\_DEVCONF[18] TVOUTBYPASS

Texas Instruments provides a global solution with an OMAP device associated with a TWL4030 power IC. The power pin vdda\_dac is software controlled by the power IC.

**15.2.4.1 TV Output and Data Format**

The output data to the TV set are the analog composite data from the DAC. The following video standards are supported:

- NTSC-J, M
- PAL-B, D, G, H, I
- PAL-M

**15.2.4.2 Digital-to-Analog Converter**

The DAC includes the following main features:

- 1.0-V-to-1.3-V digital power supply, 1.8-V analog power supply
- 10-bit resolution
- DNL within 1 LSB and INL within 1 LSB
- Sample rate of up to 60 megasamples per second (MSPS)
- Support composite/S-video dc or ac coupled output
- Full-scale voltage output: 0.88 V<sub>pp</sub> with a 75- $\Omega$  load
- Internal TV detect feature
- Signal-to-noise ratio (SNR) is 54 dB (taking into account the ac coupling)
- Suitable for low-power wireless applications; total power: 10 mA (no load in dc-coupled mode)
- Power-down mode with less than 2.5- $\mu$ A standby current
- Differential gain error and differential phase error: 1.5% and 1%, respectively

**Note:** To enhance the TV color display, it is highly recommended to set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit.

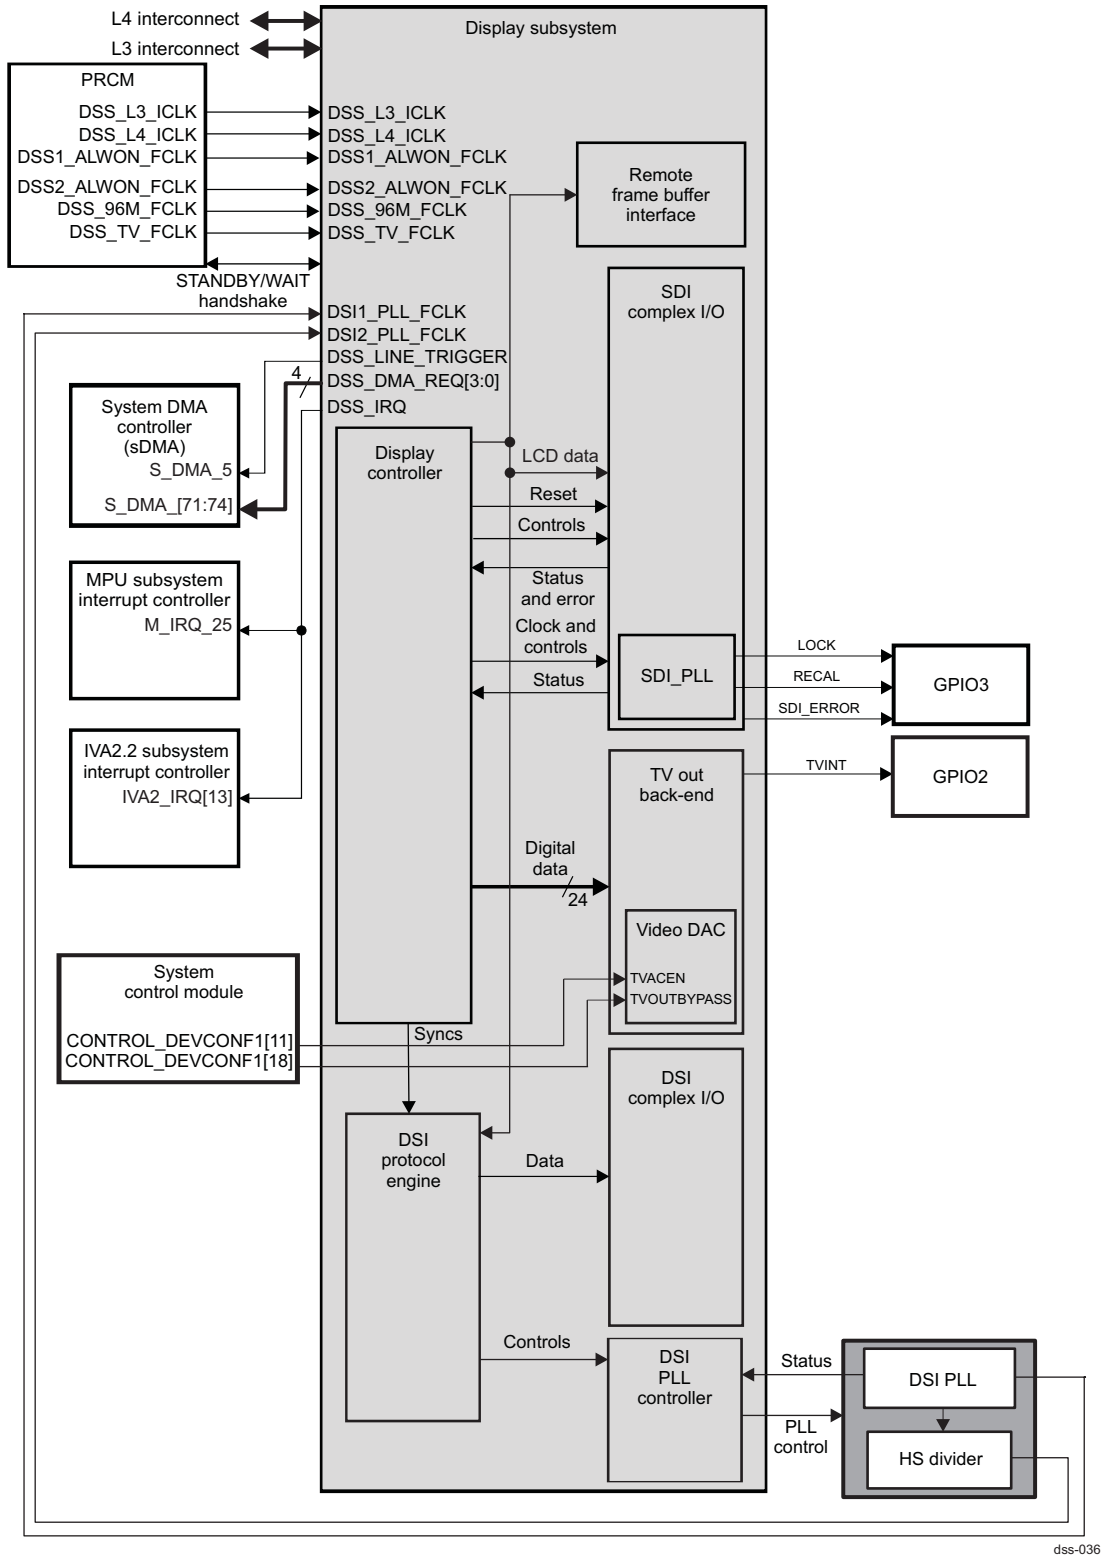

---

### 15.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

[Figure 15-64](#) shows the integration of the display subsystem in the device.

Figure 15-64. Display Subsystem Integration

### 15.3.1 Clocking, Reset, and Power-Management Scheme

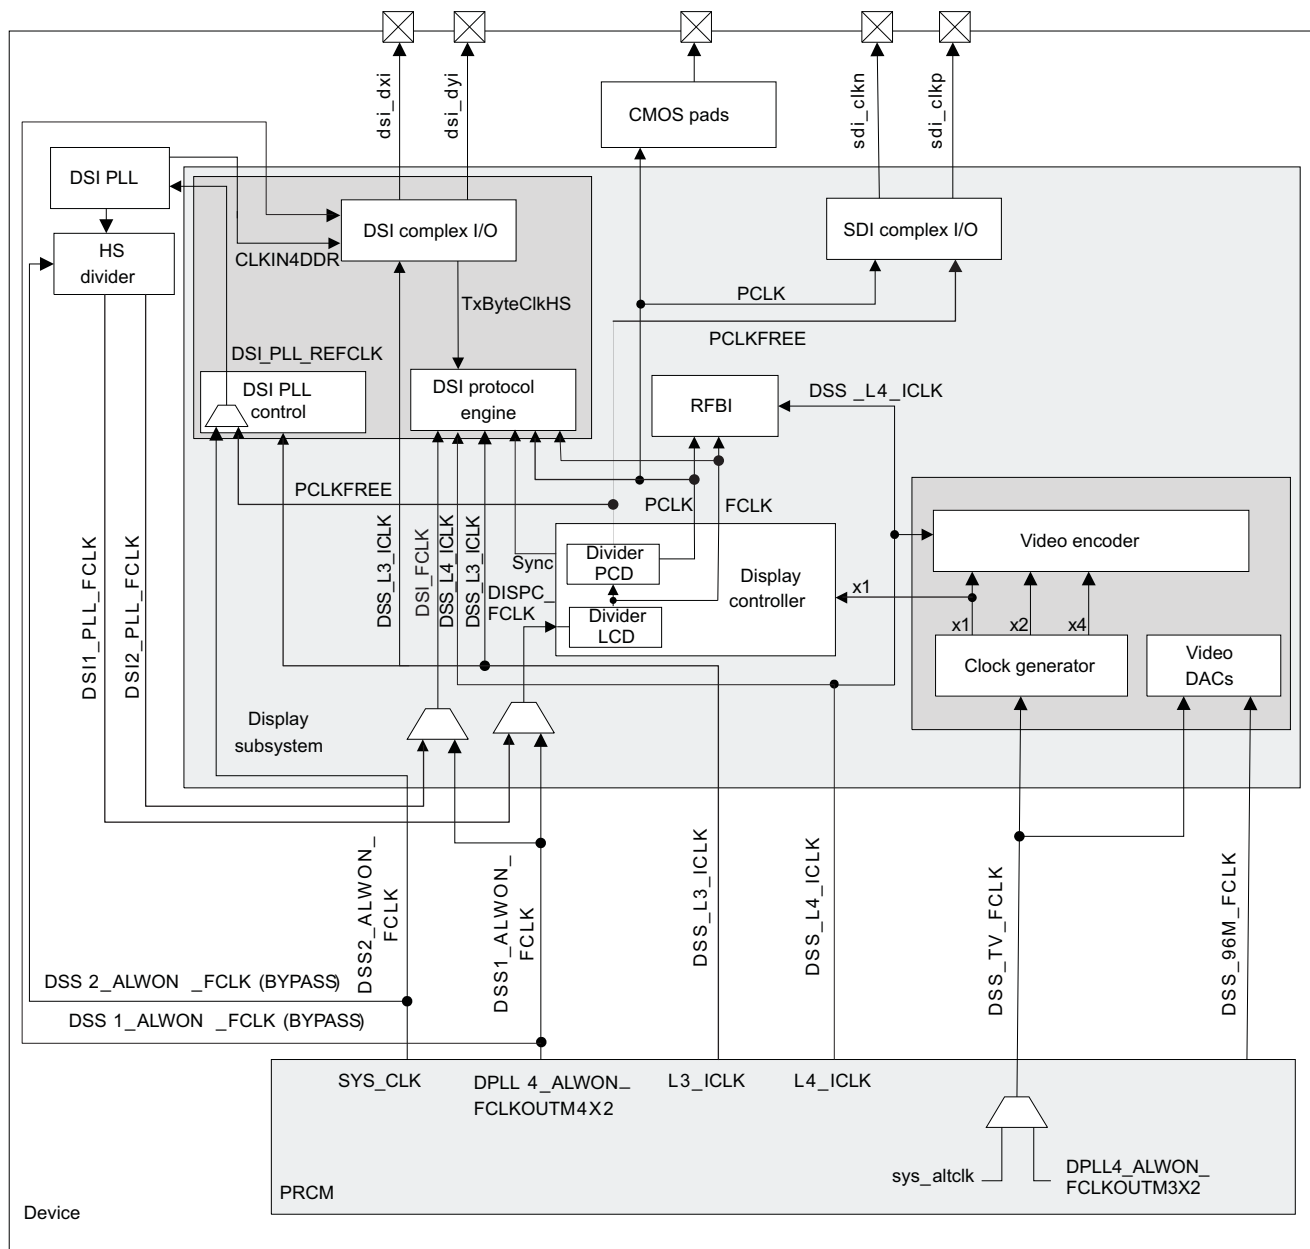

#### 15.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides six clock signals to the display subsystem: The L3 interface clock (DSS\_L3\_ICLK) and the L4 interface clock (DSS\_L4\_ICLK), with frequencies equal to the L3 interconnect clock and the L4 interconnect clock, respectively; two configurable functional clocks (DSS1\_ALWON\_FCLK and DSS2\_ALWON\_FCLK); and two other functional clocks (DSS\_TV\_FCLK and DSS\_96M\_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK.

Figure 15-65 details the clock tree for the display subsystem.

Figure 15-65. Display Subsystem Clock Tree

dss-158

**Note:** A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal, named DISPC\_UPDATE\_SYNC, is used to inform the DSI protocol engine that it must be unsynchronized with the display controller.

Table 15-18 describes the different clocks with their possible frequency values.

**Table 15-18. Display Subsystem Clocks**

Clock Signal	Attribute	Module	Frequency	Comment
DSS_L3_ICLK	L3 interface clock	DSS	(See Chapter 4, PRCM)	L3 interface clock from PRCM
DSS_L4_ICLK	L4 interface clock	DSS	(See Chapter 4, PRCM)	L4 interface clock from PRCM
DSS1_ALWON_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)
DSS2_ALWON_FCLK	Functional clock	DSI PLL	12/13/16.8/19.2/26/38.4 MHz	From PRCM: SYS_CLK
DSI1_PLL_FCLK	Functional clock	DISPC	Up to 173 MHz at nominal voltage	From DSI PLL and HS divider
DSI2_PLL_FCLK	Functional clock	DSI protocol engine	Up to 173 MHz at nominal voltage	From DSI PLL and HS divider
DSS_TV_FCLK	Functional clock	DSS, video mode DAC	54 MHz or sys_alt_clk (up to 59 MHz)	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or External input clock (See Chapter 4, PRCM)
DSS_96M_FCLK	Functional clock	Video DAC	96 MHz	From PRCM: 96M_FCLK

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit to enable DSS1\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit to enable DSS2\_ALWON\_FCLK
- PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit to enable DSS\_TV\_FCLK and DSS\_96M\_FCLK

To enable or disable the DSS\_L3\_ICLK and DSS\_L4\_ICLK interface clocks, write (1: Enable, 0: Disable) to the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit.

**Note:** Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS\_L3\_ICLK clock is only used by the display controller interface to fetch the pixel data. The DSS\_L4\_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

**Note:** A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. The SDI module and all the display subsystem registers are configured through the display subsystem register.

- Display controller functional clocks

The display controller can use either the DSS1\_ALWON\_FCLK or the DSI1\_PLL\_FCLK functional clock.

To select the DSS1\_ALWON\_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit; to select the DSI1\_PLL\_FCLK functional clock, write 1 in the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit.

---

**Note:** The DSS1\_ALWON\_FCLK and DSI1\_PLL\_FCLK functional clocks must be active (the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC\_CONTROL[5] GOLCD bit is set to 1.

---

Depending on the DPLL4 input clock frequency, the DSS1\_ALWON\_FCLK can be adjusted by setting the PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field.

- DSI PLL functional clock (DSI\_PLL\_REFCLK)  
The DSI PLL controller module can use either the DSS2\_ALWON\_FCLK (from PRCM) or the PCLKFREE (from DISPC) functional clock. To select the DSS2\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit.
- DSI protocol engine functional clocks (DSI\_FCLK)  
The DSI protocol engine can use either the DSS1\_ALWON\_FCLK (from PRCM) or the DSI2\_PLL\_FCLK (from DSI PLL) functional clock. To select the DSS1\_ALWON\_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS\_CONTROL[1] DSI\_CLK\_SWITCH bit; to select the DSI2\_PLL\_FCLK functional clock, write 1 in the DSS.DSS\_CONTROL[1] DSI\_CLK\_SWITCH bit.

---

**Note:** It is possible to switch between these two clocks, even when both of them are not active.

---

- There are five clock domains in the DSI module:
  - Byte clock domain:  
TxByteClkHS is generated from the bit clock and converted into a byte clock. The maximum frequency is 100 MHz (all OPPs). It is generated by the DSI complex I/O.
  - Functional clock domain  
The DSI\_FCLK is the functional clock for the DSI protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 124 MHz (low voltage). It should always be equal to or higher than the byte (TxByteClkHS), L4 interconnect (DSS\_L4\_ICLK), and video port (VP\_CLK) clocks. The software must configure the clocks correctly.
  - L4 interface clock domain  
The DSS\_L4\_ICLK is used in the L4 interconnect port domain. The maximum frequency is 166 MHz at nominal voltage and 83 MHz at low voltage.
  - The video port domain  
The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP\_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.
  - Serial Configuration Port (SCP) and Power Control (PWR) interfaces  
The DSS\_L4\_ICLK is the functional clock.

---

**Notes:**

- There is no clock domain for RxClkEsc because it is used as an enable and not as a clock by the DSI protocol engine module
  - The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR because both of them use DSS\_L4\_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface should be balanced.
  - If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.
- 
- Video encoder functional clock  
The DSS\_TV\_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 15-19](#)).

**Table 15-19. Possible Digital Clock Division for the Video Encoder**

Clock Output	Clock Mode	
	Clock mode 0	Clock mode 1
Video encoder clock 4x	DSS_TV_FCLK	DSS_TV_FCLK or 0 (gated)
Video encoder clock 2x	DSS_TV_FCLK/2	DSS_TV_FCLK
Video encoder clock 1x	DSS_TV_FCLK/4	DSS_TV_FCLK/2

**Note:** Clock mode 1 can be used for power-saving purposes, or if a 27-MHz external clock is provided to the video encoder.

DSS\_TV\_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM\_CLKSEL\_DSS[12:8] CLKSEL\_TV bit field. If the DPLL4 is selected, the DSS\_TV\_FCLK is provided by the DPLL4\_ALWON\_FCLKOUTM3X2 clock.

**Note:** If the DSS\_TV\_FCLK is not provided by DPLL4 but rather by the sys\_alt\_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel, and a 59-MHz clock is needed for PAL square pixel.

- Dual video DAC clocks  
The dual video DAC uses two distinct clocks: The DSS\_TV\_FCLK and the DSS\_96M\_FCLK. The video data are latched on the positive edge of the DSS\_TV\_FCLK clock. On the other hand, the video DAC uses the DSS\_96M\_FCLK fixed-frequency clock internally as the clock input for the switch capacitor resistor.
- SDI functional clock  
The display controller provides the functional clocks PCLK (pixel clock) and PCLKFREE (free-running pixel clock) of the SDI module, which is derived from the display controller functional clock. The SDI module functional clock drives the phase-locked loop SDI\_PLL that multiplies and divides the PCLK frequency by two programmable factors for the serial connection.

**Note:** When using the SDI, configure the PCLK in the free-running mode by setting the DSS.DISPC\_CONTROL[27] PCLKFREEENABLE bit to 1.

### 15.3.1.2 Resets

#### 15.3.1.2.1 Hardware Reset

The display subsystem receives its reset signal DSS\_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

#### 15.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write to the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS\_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

**Note:** The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC\_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI\_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI\_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write to these registers.

### CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

#### 15.3.1.3 Power Domain

The display subsystem modules are on the display subsystem (DSS) power domain and on the VDD2 voltage domain, except for the dual video DACs, which are on the analog vdda\_dac voltage domain.

#### 15.3.1.4 Power Management

##### 15.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured in one of the following clock activity modes:

- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC\_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM\_CLKSTST\_DSS[0] CLKACTIVITY\_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

**Note:** The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM\_AUTOIDLE\_DSS[0] AUTO\_DSS bit:

- When the AUTO\_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
- When the AUTO\_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.

#### 15.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC\_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

---

**Note:** All the bits listed above (except for the FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

---

#### 15.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for RFBI.
- Smart-idle mode:
  - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).
    - The display controller does not use anymore the L4 interface clock (DSS\_L4\_ICLK).
  - DSI protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).
    - The DSI protocol engine does not use the L4 interface clock (DSS\_L4\_ICLK) anymore.
    - The SCP and PWR transactions are complete.
    - No data remains in the TX FIFO (data waiting in the FIFO to be sent to the peripheral).

To configure the display subsystem in smart-idle mode, set the DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for display controller, set the DSS.DSI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS\_L4\_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

#### 15.3.1.4.4 SDI Idle Mode

To save power consumption, the PLL (SDI\_PLL) of the SDI module can be configured in one of the operation modes shown in [Table 15-20](#) when not locked.

**Table 15-20. SDI PLL Operation Modes**

SDI_PLL Operation Mode	Stop mode Low power <sup>(1)</sup>	Stop mode Low power <sup>(1)</sup>	Idle bypass Low power	Idle bypass Fast relock	Limp
	Output clock stopped Lowest power standby	Output clock stopped Fastest start-up time	Output clock at PCLK rate Lowest power standby	Output clock at PCLK rate Fastest start-up time	Output at full speed
DSS.DSS_PLL_CONTROL[0] SDI_PLL_IDLE	0	0	1	1	1 or PCLK stops
DSS.DSS_PLL_CONTROL[20] SDI_PLL_LOWCURRSTBY	1	0	1	0	X
DSS.DSS_PLL_CONTROL[17] SDI_PLL_STOPMODE	1	1	1	1	0

<sup>(1)</sup> Recommended

#### 15.3.1.4.5 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC\_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.DISPC\_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

#### 15.3.1.4.6 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC\_SYSCONFIG[13:12] MIDDLEMODE bit field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
  - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater

than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM\_IDLEST\_DSS[0] ST\_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

#### 15.3.1.4.6.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:
  - Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

#### 15.3.1.4.6.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM\_SLEEPDEP\_DSS[1] EN\_MPU bit:

- When the EN\_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN\_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM\_SLEEPDEP\_DSS[2] EN\_IVA2 bit:

- When the EN\_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN\_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

#### 15.3.1.4.6.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
  - DSS1\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit is set to 0 and the display subsystem is in standby mode.
  - DSS2\_ALWON\_FCLK is shut down when the PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit is set to 0 and the display subsystem is in standby mode.
  - DSS\_L3\_ICLK and DSS\_L4\_ICLK are controlled together. They are shut down when the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit is set to 0 and the display subsystem is in standby mode.

#### **CAUTION**

Do not stop DSS1\_ALWON\_FCLK, or DSS2\_ALWON\_FCLK clock (if used) if the display subsystem is not disabled.

**CAUTION**

DSS\_TV\_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS\_TV\_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS bit field:

- When the CLKTRCTRL\_DSS bit field is set to 0x0 (reset value), the automatic transition is disabled
- When the CLKTRCTRL\_DSS bit field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS bit field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL\_DSS bit field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

#### 15.3.1.4.6.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup

- Set the display subsystem in smart standby mode.
- Manually enable DSS\_L3\_ICLK and DSS\_L4\_ICLK.
- Manually enable DSS1\_ALWON\_FCLK or DSS2\_ALWON\_FCLK.
- Manually enable DSS\_TV\_FCLK if the video encoder is used.
- Set the PRCM.CM\_CLKSTCTRL\_DSS[1:0] CLKTRCTRL\_DSS bit field to 0x3 (autocontrol mode supervised by hardware).

- Shut down the display subsystem.

- Disable the display subsystem.
- Manually disable DSS1\_ALWON\_FCLK, DSS2\_ALWON\_FCLK, DSS\_TV\_FCLK, DSS\_L3\_ICLK, and DSS\_L4\_ICLK.

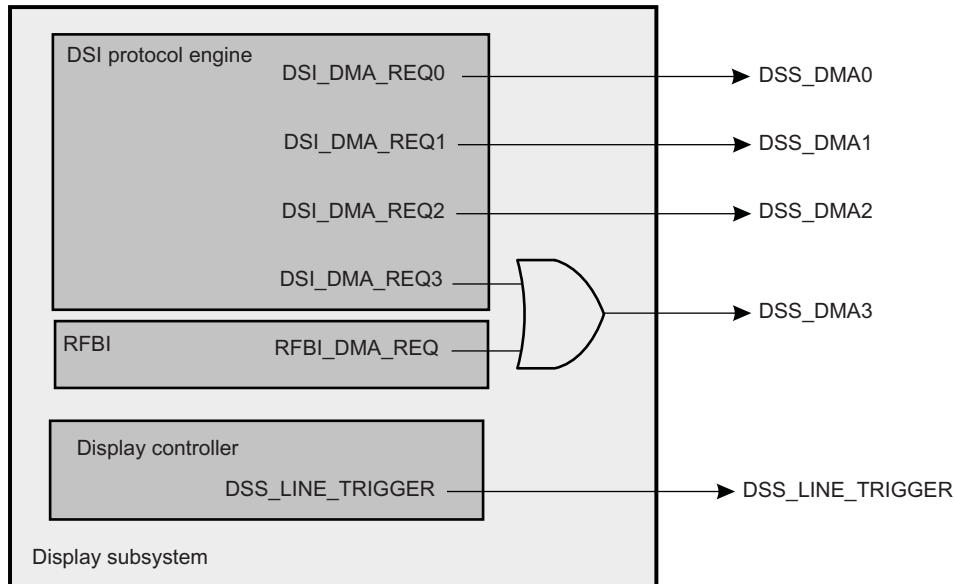

For more details on low-power programming settings, see [Section 15.6.2](#).

## 15.3.2 Hardware Requests

### 15.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. Figure 15-66 details the DMA tree.

**Figure 15-66. Display Subsystem DMA Tree**

dss-159

**Table 15-21. DSS DMA Requests Description**

DMA Request Name	DSS Module	Mapping	Description
DSS_LINE_TRIGGER	DISPC	S_DMA_5	See <a href="#">Section 15.3.2.1.1</a>
DSI_DMA_REQ0	DSI protocol engine	S_DMA_71	See <a href="#">Section 15.3.2.1.2</a>
DSI_DMA_REQ1	DSI protocol engine	S_DMA_72	See <a href="#">Section 15.3.2.1.2</a>
DSI_DMA_REQ2	DSI protocol engine	S_DMA_73	See <a href="#">Section 15.3.2.1.2</a>
DSI_DMA_REQ3	DSI protocol engine	S_DMA_74	See <a href="#">Section 15.3.2.1.2</a>
RFBI_DMA_REQ	RFBI	S_DMA_74	See <a href="#">Section 15.3.2.1.3</a>

**Note:** The DMA requests from the RFBI module (RFBI\_DMA\_REQ) and the DSI protocol engine (DSI\_DMA\_REQ3) are merged on line DSS\_DMA3. The software must only use DSS\_DMA3 on one module at a time (RFBI or DSI protocol engine).

#### 15.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS\_LINE\_TRIGGER) is connected to the sDMA by the sDMA controller (S\_DMA\_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in [Section 15.3.2.2, Interrupt Requests](#). This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS\_LINE\_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC\_LINE\_NUMBER[10:0] LINENUMBER bit field.

### 15.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported.

### 15.3.2.1.3 RFBI DMA Request

The RFBI\_DMA\_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

### 15.3.2.2 Interrupt Requests

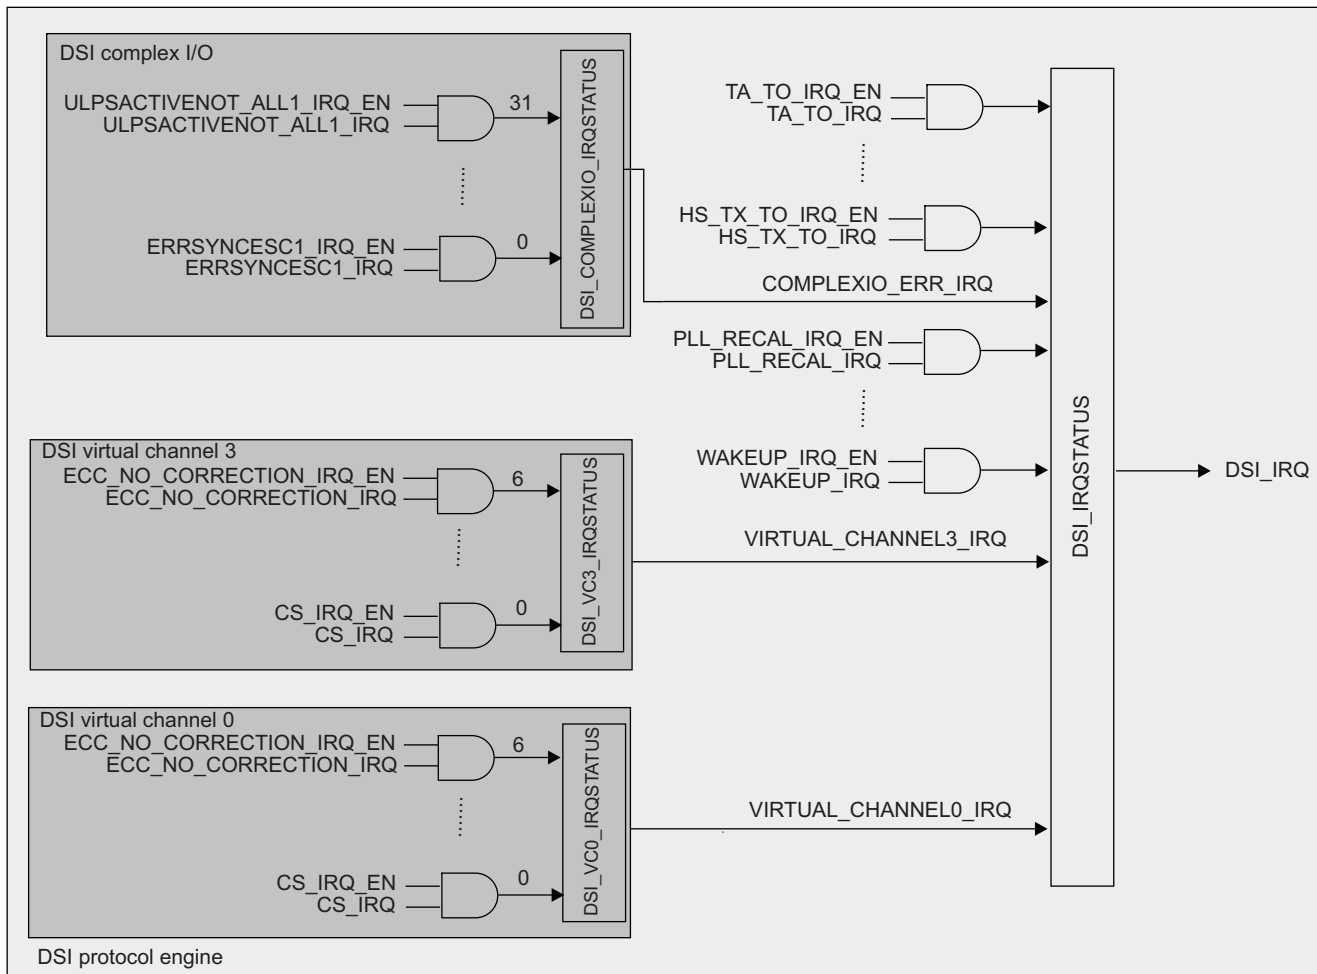

The DSI protocol engine, the DSI complex I/O (DSI\_IRQ), and the display controller (DISPC\_IRQ) generate one interrupt request each. The DSI\_IRQ and DISPC\_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS\_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M\_IRQ\_25 input line)
- IVA interrupt handler (IVA2\_IRQ[13] input line)

Figure 15-67 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

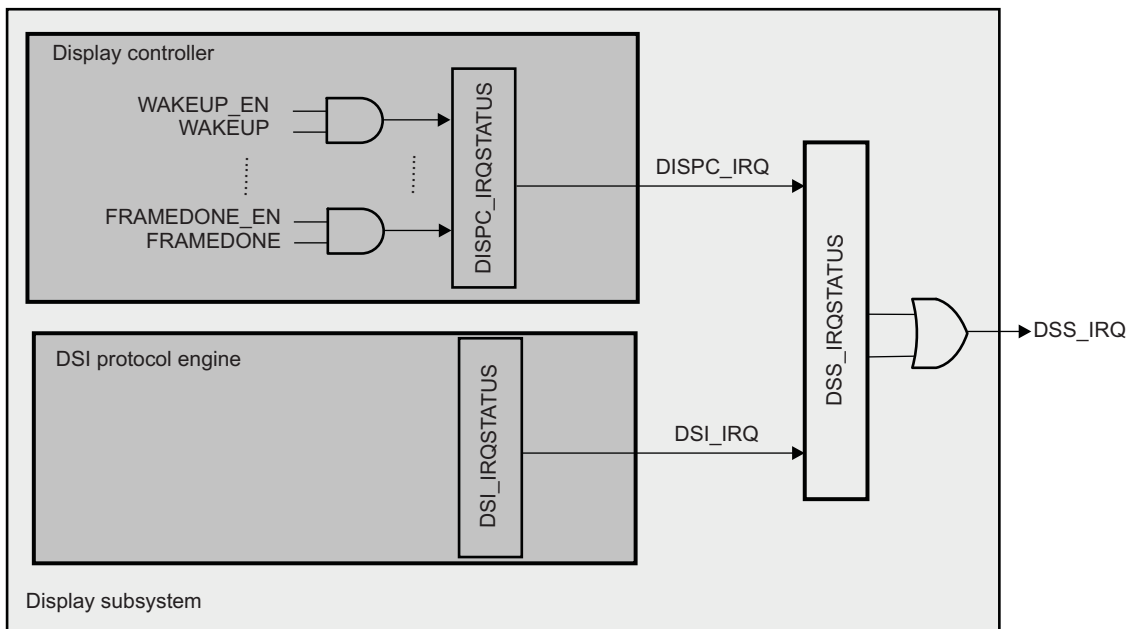

Figure 15-67. DSI Interrupt Tree

dss-160

Figure 15-68 details the interrupt tree for the DISPC and the display subsystem.

Figure 15-68. DISPC and DSS Interrupts Tree

dss-161

15.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC\_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC\_IRQSTATUS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See Section 15.7, Display Subsystem Register Manual, for more information on checking and clearing interrupt events.

Table 15-22 lists the display subsystem interrupt events.

Table 15-22. Display Subsystem Interrupts

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN <sup>(1)</sup>	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD <sup>(1)</sup>	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.

<sup>(1)</sup> EVYNC interrupts (EVSYNC\_EVEN and EVSYNC\_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

**Table 15-22. Display Subsystem Interrupts (continued)**

Interrupt Name	Description
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTDIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

**Note:** To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC\_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC\_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits. Check the interrupts.  
LCD: Verify that a FRAMEDONE interrupt occurs.  
TV : Verify that EVSYNC\_EVEN or EVSYNC\_ODD interrupts occur.
2. Set the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

**Note:** The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), should not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC\_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC\_IRQENABLE[15] SYNCLOSTDIGITAL bit.

### 15.3.2.2.2 DSI Interrupt Request

The DSI protocol engine requires a single interrupt line, DSI\_IRQ. The DSS.DSI\_IRQSTATUS register indicates the general interrupt events. Refer to [Table 15-23](#). Each VC and complex I/O has a dedicated interrupt register: DSS.DSI\_VCn\_IRQSTATUS and DSS.DSI\_COMPLEXIO\_IRQSTATUS respectively. Refer to [Table 15-24](#) and [Table 15-25](#).

[Table 15-23](#) indicates the DSI global interrupt events.

**Table 15-23. DSI Global Interrupts**

Interrupt Name	Description
RESYNCHRONIZATION_IRQ	Resynchronization in video mode
TA_TO_IRQ	Turn-around timer expired
LDO_POWER_GOOD_IRQ	Signal LDOPWRGOOD from the DSI_PHY changes its state for the supply VDDALDODSIPLL from up to down or down to up.
SYNC_LOST_IRQ	Synchronization with video mode port is lost (video mode only)
ACK_TRIGGER_IRQ	Acknowledge trigger is received
TE_TRIGGER_IRQ	Tearing effect trigger is received
WAKEUP_IRQ	Occurs when the SWakeUp signal is asserted
HS_TX_TO_IRQ	High speed TX Time-out Interrupt
LP_RX_TO_IRQ	Low speed RX Time-out Interrupt

**Table 15-23. DSI Global Interrupts (continued)**

Interrupt Name	Description
COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: The interrupt is triggered when any error is received from the complex I/O (events are defined in <a href="#">DSI_COMPLEXIO_IRQSTATUS</a> ).
PLL_RECAL_IRQ	PLL recal event (assertion of DSISRecal signal from the DSI PLL Control module)
PLL_UNLOCK_IRQ	PLL unlock event (deassertion of DSISLock signal from the DSI PLL Control module)
PLL_LOCK_IRQ	PLL lock event (assertion of DSISLock signal from the DSI PLL Control module)
VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: The interrupt is triggered when an error is received from DSI Virtual Channel3 (events are defined in <a href="#">DSI_VC3_IRQENABLE</a> ).
VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: The interrupt is triggered when an error is received from DSI Virtual Channel2 (events are defined in <a href="#">DSI_VC2_IRQENABLE</a> ).
VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: The interrupt is triggered when an error is received from DSI Virtual Channel1 (events are defined in <a href="#">DSI_VC1_IRQENABLE</a> ).
VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: The interrupt is triggered when an error is received from DSI Virtual Channel0 (events are defined in <a href="#">DSI_VC0_IRQENABLE</a> ).

[Table 15-24](#) indicates the DSI complex I/O interrupt events.

**Table 15-24. DSI Complex I/O Interrupts**

Interrupt Name	Description
ULPSActiveNot_ALL0_IRQ	All signals ULPSActiveNOT are 0
ULPSActiveNot_ALL1_IRQ	All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high
STATEULPS3_IRQ	Lane #3 in ultralow-power state
STATEULPS2_IRQ	Lane #2 in ultralow-power state
STATEULPS1_IRQ	Lane #1 in ultralow-power state
ERRCONTROL3_IRQ	Control error for lane #3
ERRCONTROL2_IRQ	Control error for lane #2
ERRCONTROL1_IRQ	Control error for lane #1
ERRESC3_IRQ	Escape entry error for lane #3(edge trigger interrupt)
ERRESC2_IRQ	Escape entry error for lane #2 (edge trigger interrupt)
ERRESC1_IRQ	Escape entry error for lane #1 (edge trigger interrupt)
ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for lane #1
ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for lane #1
ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for lane #2
ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for lane #2
ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for lane #3
ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for lane #3
ERRSYNCESC3_IRQ	Low power Data transmission synchronization error for lane #3
ERRSYNCESC2_IRQ	Low power Data transmission synchronization error for lane #2
ERRSYNCESC1_IRQ	Low power Data transmission synchronization error for lane #1

---

**Note:** The error contention signals for DX and DY signals of each lane are ORed together.

---

Table 15-25 indicates the DSI VCs interrupt events

**Table 15-25. DSI Virtual Channel Interrupts**

<b>Interrupt Name</b>	<b>Description</b>
ECC_CORRECTION_IRQ	Virtual channel - ECC has been used to correct a 1-bit error (short and long packet only). Indicates whether a 1-bit error correction occurred using the ECC.
PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used
CS_IRQ	Virtual channel - Check-Sum of the payload mismatch detection
FIFO_RX_OVF_IRQ	RX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the DSI link has overflowed
FIFO_TX_OVF_IRQ	TX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the L4 interconnect slave port has overflowed
BTA_IRQ	Bus turnaround is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral is used to determine which VC is used to flag the interrupt)
ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error
FIFO_TX_UDF_IRQ	TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L4 interconnect port has under-flowed in the middle of a packet transfer

## 15.4 Display Subsystem Functional Description

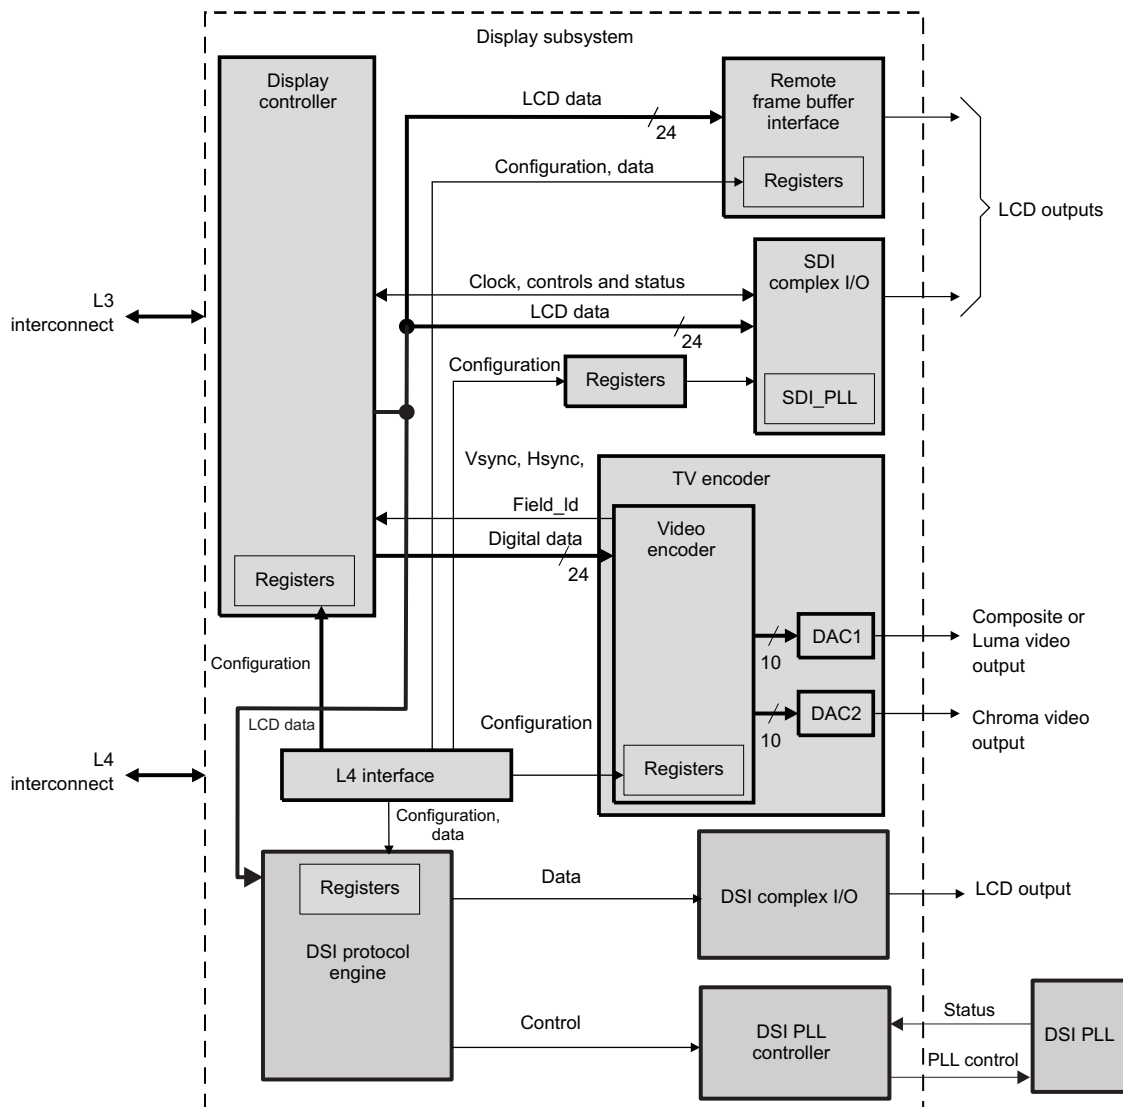

This section describes the functionalities of the LCD and TV display supports by describing the following modules: Display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI, SDI, and video encoder.

The functionalities of the display controller are common to both LCD and TV data paths; the RFBI and SDI functionalities are LCD-specific; and the video encoder functionalities are specific to the TV set.

### 15.4.1 Block Diagram

Figure 15-69 is a schematic of the display subsystem.

**Figure 15-69. Display Subsystem Full Schematic**

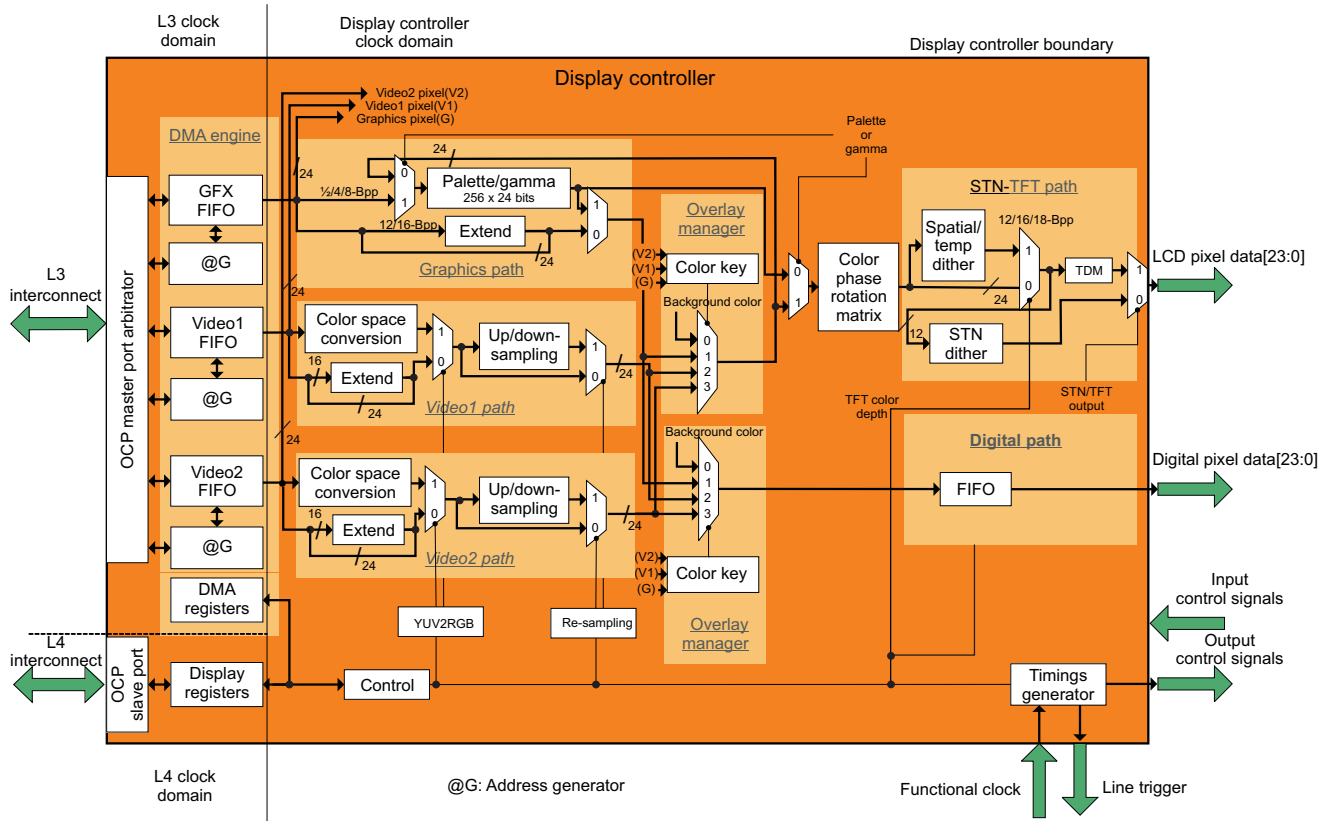

dss-037

### 15.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 15-70).

Figure 15-70. Display Controller Architecture Overview

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

## 15.4.2.1 Display Modes

### 15.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

### 15.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

## 15.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

### 15.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 1-BPP data memory organization (CLUT) (big endian)

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (little endian)

- BITMAP 2-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (big endian)

- BITMAP 2-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (little endian)

- BITMAP 4-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (big endian)

- BITMAP 4-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 8-BPP data memory organization (CLUT) (little endian)

- BITMAP 8-BPP data memory organization (CLUT) (big endian)

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian)

- ARGB 16-BPP data memory organization (big endian)

- RGB 24-BPP data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian)

- RGBA 32-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

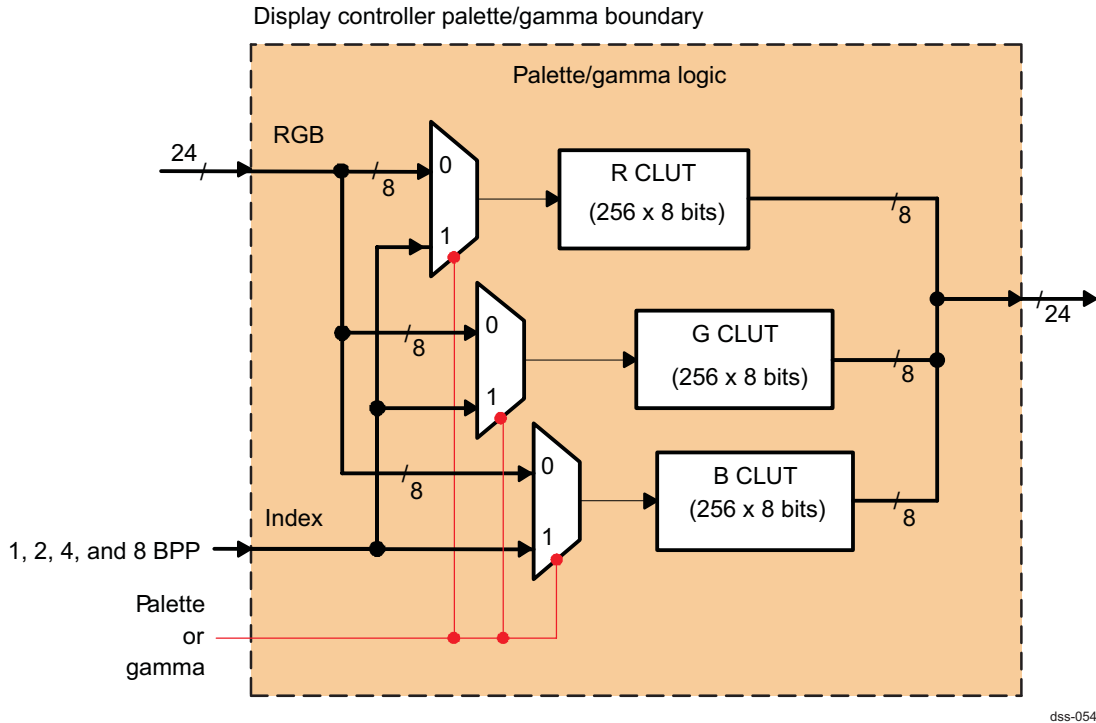

### 15.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 15-71](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

**Figure 15-71. Palette/Gamma Correction Architecture**

dss-054

#### 15.4.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In the color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In the monochrome mode, only one 8-bit value is present.

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology  
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology  
The palette is bypassed in 12, 16, and 24 BPP, allowing up to  $2^{24} = 16,777,216$  colors to be displayed.

#### 15.4.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component.

### 15.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

dss-T055

- If replication logic is ON:

dss-T056

- If replication logic is OFF:

dss-T057

### 15.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV422 pixels.

#### 15.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- RGB 12-BPP data memory organization (little endian)

dss-T046

- RGB 12-BPP data memory organization (big endian)

dss-T067

- RGB 16-BPP data memory organization (little endian)

dss-T048

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian + video 2 channel only)

- ARGB 16-BPP data memory organization (big endian + video 2 channel only)

- RGB 24-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)

- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)

- UYVY 4:2:2 data memory organization (little endian)

- UYVY 4:2:2 data memory organization (big endian)

- YUV2 4:2:2 data memory organization (little endian)

- YUV2 4:2:2 data memory organization (big endian)

### 15.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. Figure 15-72 and Figure 15-73 detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

**Figure 15-72. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)**

dss-061

**Figure 15-73. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)**

dss-060

The interpolation of the missing chrominance component is given by the equation in [Figure 15-74](#).

**Figure 15-74. Interpolation of the Missing Chrominance Component**

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV422 format is converted into YUV444. The YUV422-to-YUV444 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16235] and [16240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 15-75](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

**Figure 15-75. YCbCr to RGB Registers (VIDFULLRANGE=0)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

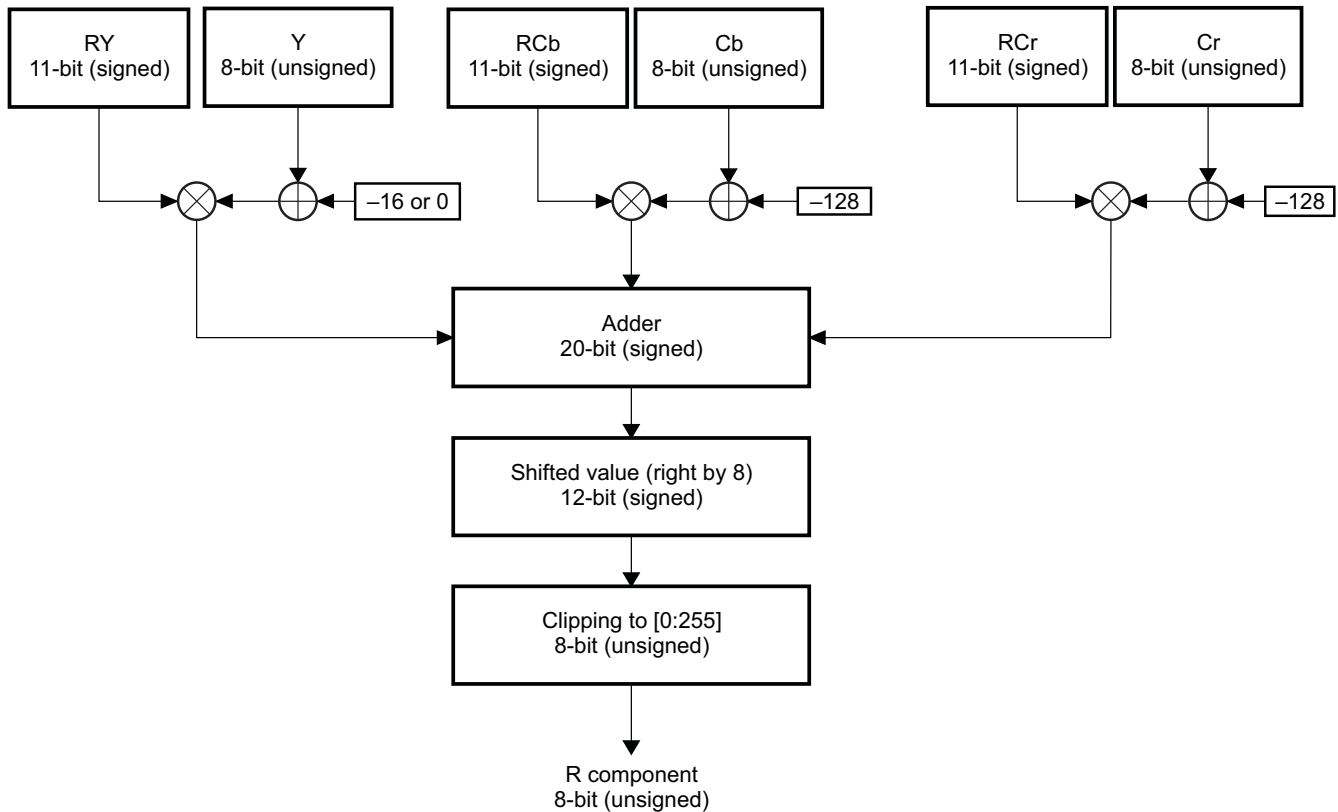

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 15-76](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

**Figure 15-76. YCbCr to RGB Registers (VIDFULLRANGE=1)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 15-77](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

**Figure 15-77. Color Space Conversion Macro-Architecture**

dss-065

#### 15.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

#### 15.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV422

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently (R, G, and B).

For the horizontal up-/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(15-1)

For the vertical up-/downsampling, the equation is R component with three taps):

$$R_{out}(n) = \left( \sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \tag{15-2}$$

dss-E067

For the vertical up-/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \tag{15-3}$$

dss-E068

*R<sub>out</sub>*: R component output

*C<sub>i</sub>(Φ)*  
dss-E069 : FIR filter coefficients

*R<sub>in</sub>*: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

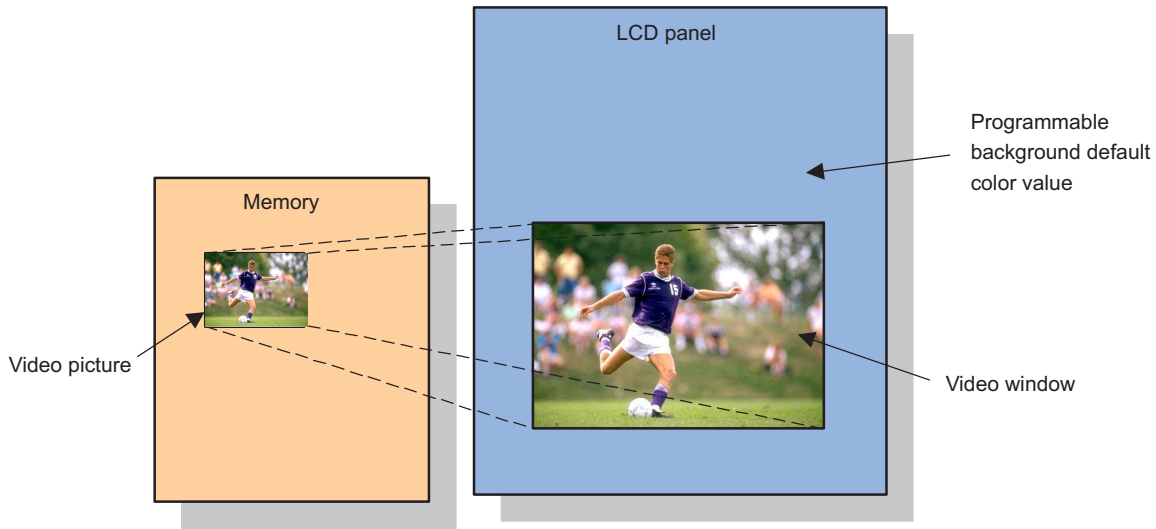

---

**Note:** The coefficients *C<sub>i</sub>(Φ)* depend on the phase between input and output pixels.

---

Figure 15-78 shows an example of video upsampling.

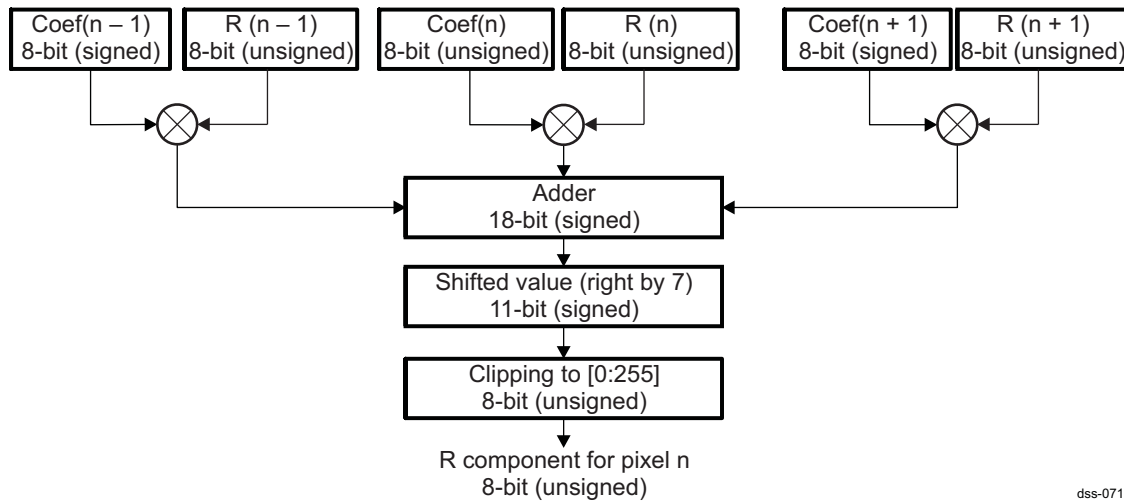

**Figure 15-78. Video Upsampling**

dss-070

**Filter Description**

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is /2. The downsampling ratio using 5-tap configuration is /4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 15-79 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

**Figure 15-79. Resampling Macro-Architecture (3-Coefficient Processing)**

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 15-26](#) and [Table 15-27](#).

**Ratio V when performing a vertical down-sampling only**

$$h\_ratio = \frac{DISPC\_LCD\_SIZE.PPL}{DISPC\_VID\_SIZE.VidSizeX}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeY}{DISPC\_VID\_SIZE.VidSizeY}$$

$$Ratio = \frac{v\_ratio}{2 \times h\_ratio} \quad \text{If } 1 < v\_ratio \leq 2$$

$$Ratio = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad \text{If } 1 < v\_ratio \leq 4$$

dss\_swpu108-E135

**Ratio H when performing a horizontal down-sampling only**

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeX}{DISPC\_VID\_SIZE.VidSizeX}$$

dss\_swpu108-E136

**Ratio H+V when performing a horizontal and vertical down-sampling**

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

**Table 15-26. Functional Clock Frequency Requirement in RGB16 & YUV422—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Table 15-27. Functional Clock Frequency Requirement in RGB24—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Use case example:**

An input picture of 1024\*768 is scaled to an output picture of size of 800\*600 and displayed onto a LCD of resolution 1280\*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

**Ratio V:**  $h\_ratio = 1.6$  and  $v\_ratio = 1.28$  then Ratio = 0.4

**Ratio H:** Ratio = 1.28

**Ratio H+V:** Ratio =  $\max(1.28, 0.4) = 1.28$

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 15-26](#) and [Table 15-27](#), If in RGB16-YUV422:

- 3-taps → DSS functional clock = 4 \* PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio \* PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 \* PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 \* Ratio \* PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV422 in a 5-tap configuration.

#### 15.4.2.4 Overlay Support

##### CAUTION

Enabling overlay optimization (setting the DSS.DISPC\_CONTROL [12] OVERLAYOPTIMIZATION bit) if no overlay region effectively exists (the DSS.DISPC\_VIDn\_ATTRIBUTES [0] VIDENABLE bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 15-82](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

##### 15.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

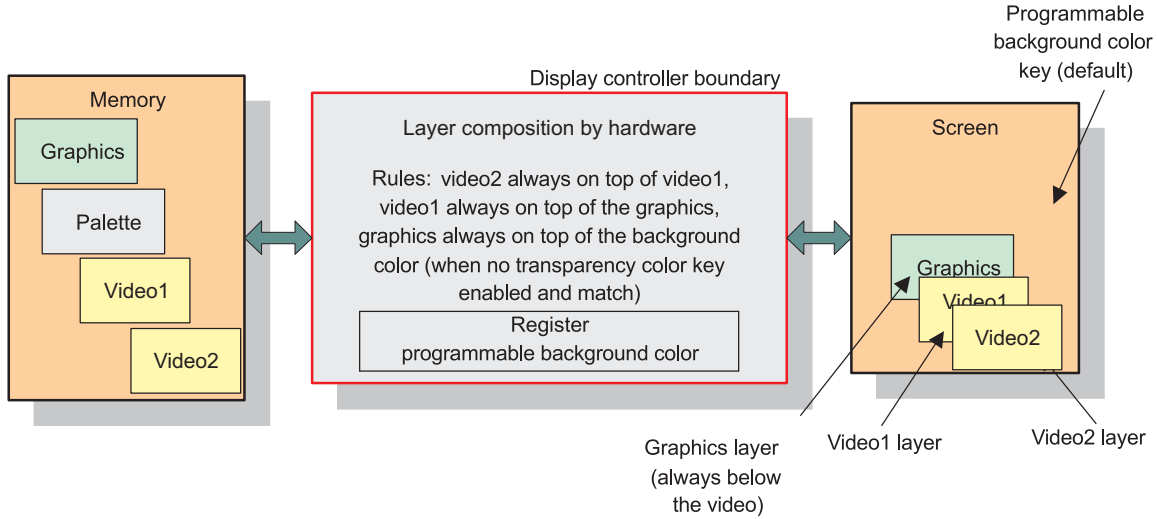

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

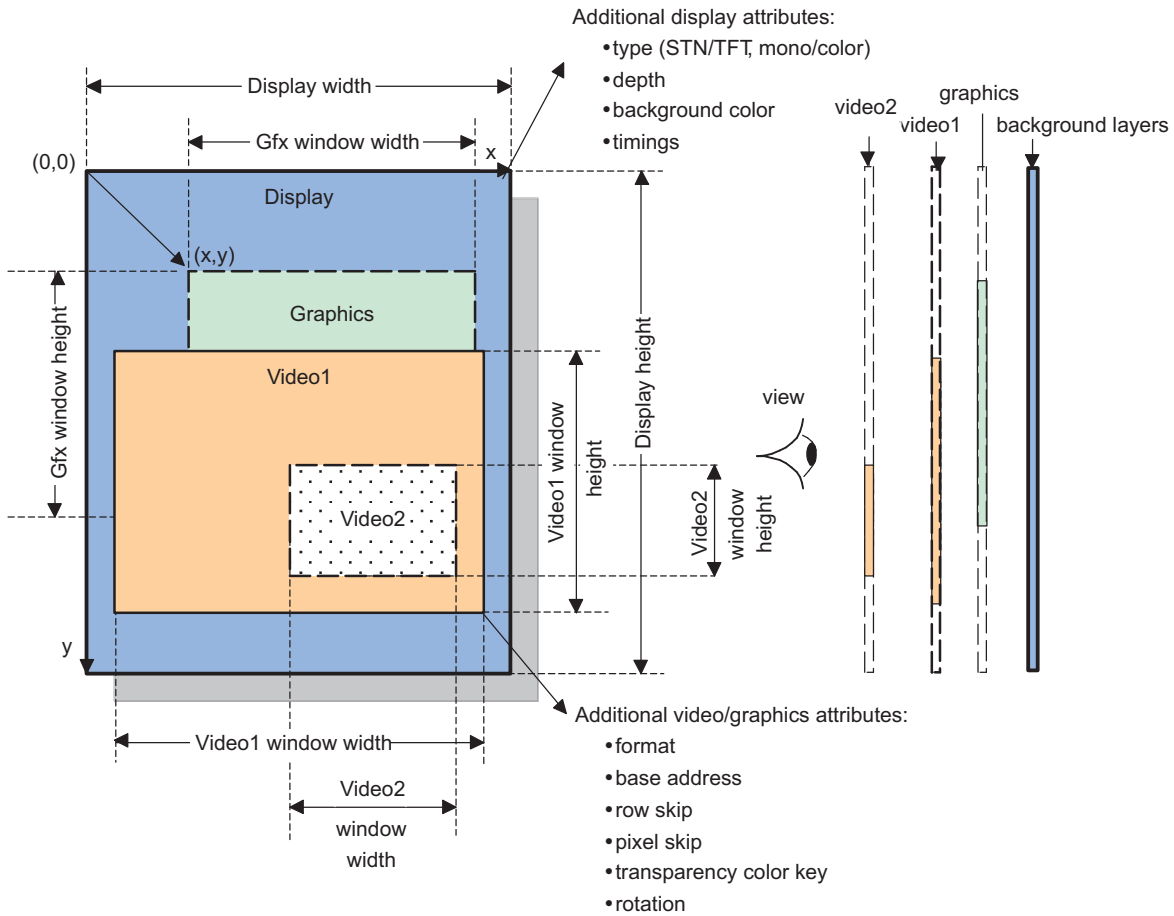

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 15-84](#)).

Figure 15-80. Overlay Manager in Normal Mode

dss-072

Figure 15-81. Display Attributes in Normal Mode

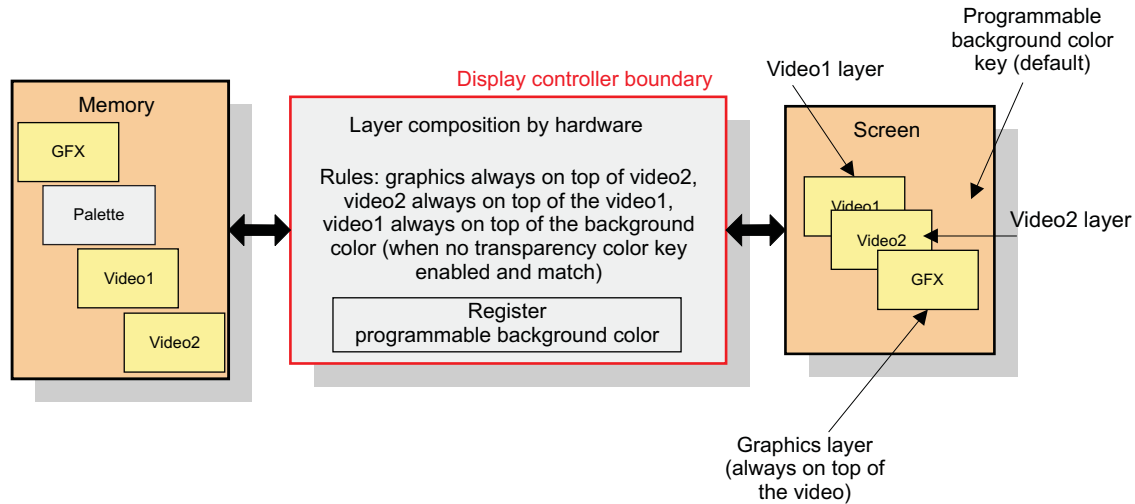

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

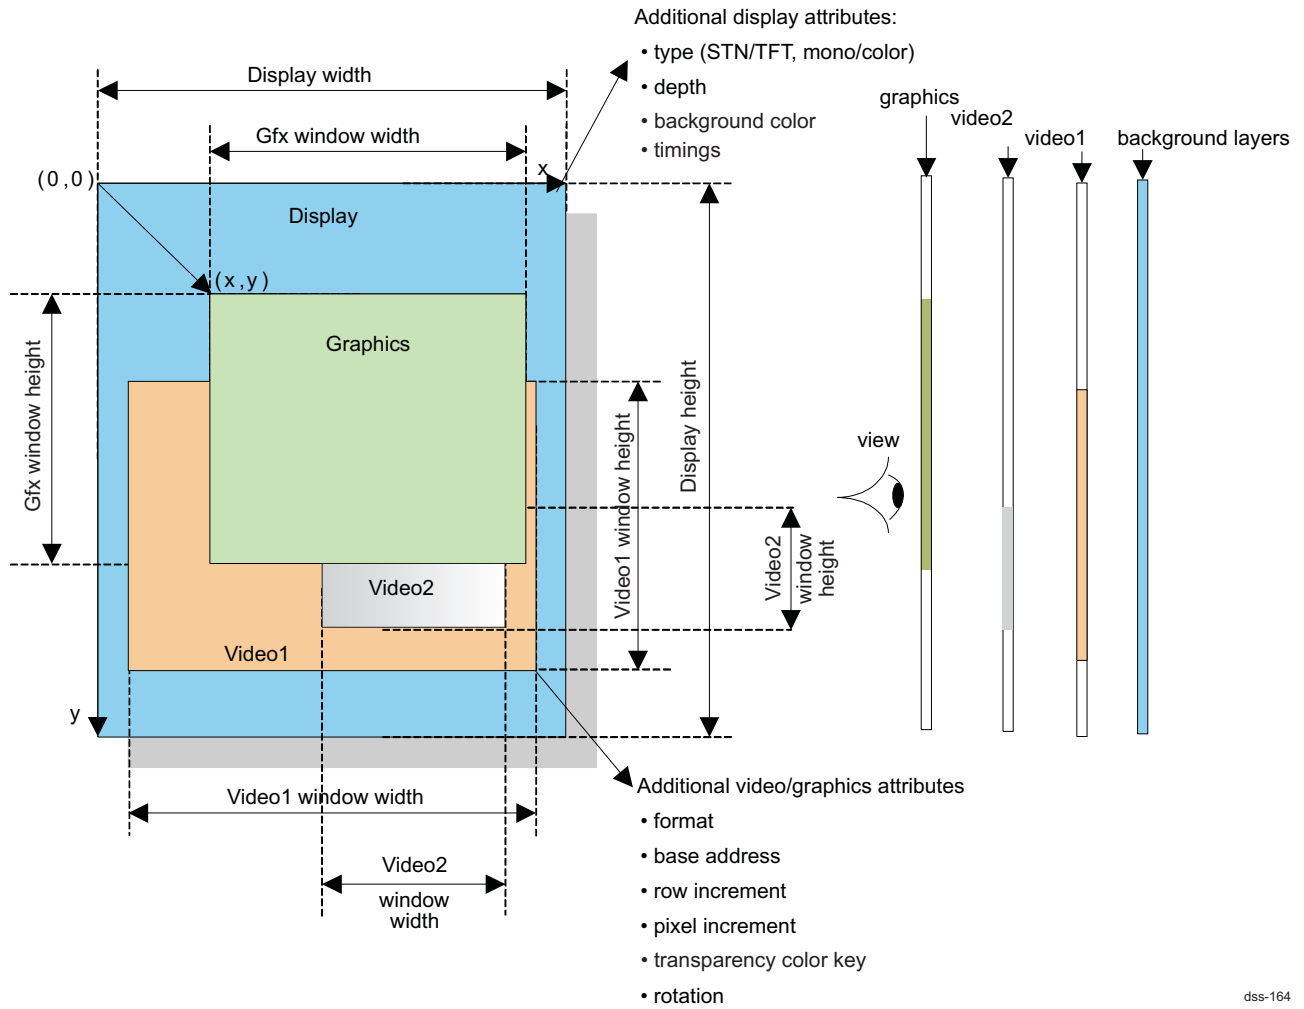

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 15-84](#)).

**Figure 15-82. Overlay Manager in Alpha Mode**

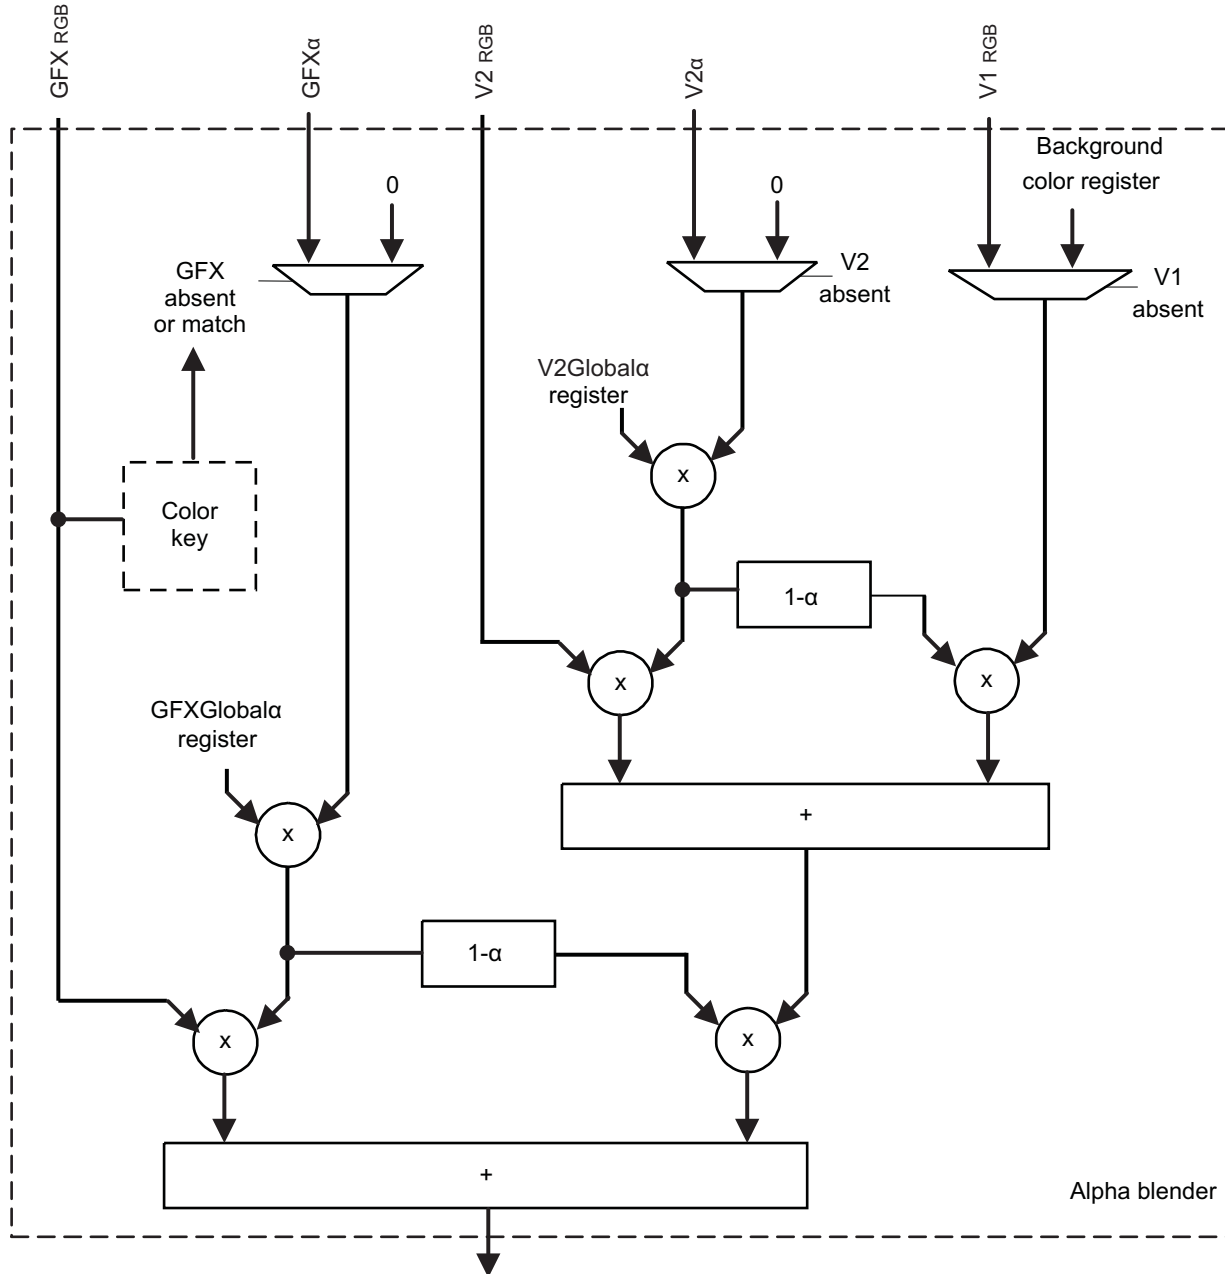

dss-163

Figure 15-83. Display Attributes in Alpha Mode

dss-164

Figure 15-84 shows the alpha blending processing in detail.

**Figure 15-84. Alpha Blending Macro Architecture**

dss-165

**Note:** "1-alpha" operator corresponds to the basic 1's complement operation.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. [Table 15-28](#) details the alpha blending 4-bit values and the corresponding blending percentage.

**Table 15-28. Alpha Blending 4-Bit Values**

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...	...	...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

#### 15.4.2.4.2 Transparency Color Keys

##### 15.4.2.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

---

**Note:** The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

---

- Video source transparency color key value:

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up-/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the `DSS.DISPC_CONFIG[11]` TCKLCDSELECTION bit for LCD output or the `DSS.DISPC_CONFIG[13]` TCKDIGSELECTION bit for digital output. Program the `DSS.DISPC_CONFIG[10]` TCKLCDENABLE bit (LCD output) or the `DSS.DISPC_CONFIG[12]` TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 15-85](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

**Figure 15-85. Video Source Transparency Example**

dss-074

- **Graphics destination transparency color key value:**  
The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.  
To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.  
An example is shown in [Figure 15-86](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

**Figure 15-86. Graphics Destination Transparency Example**

dss-075

#### 15.4.2.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

#### 15.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV422, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV422 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

#### 15.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Passive matrix technology

##### 15.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

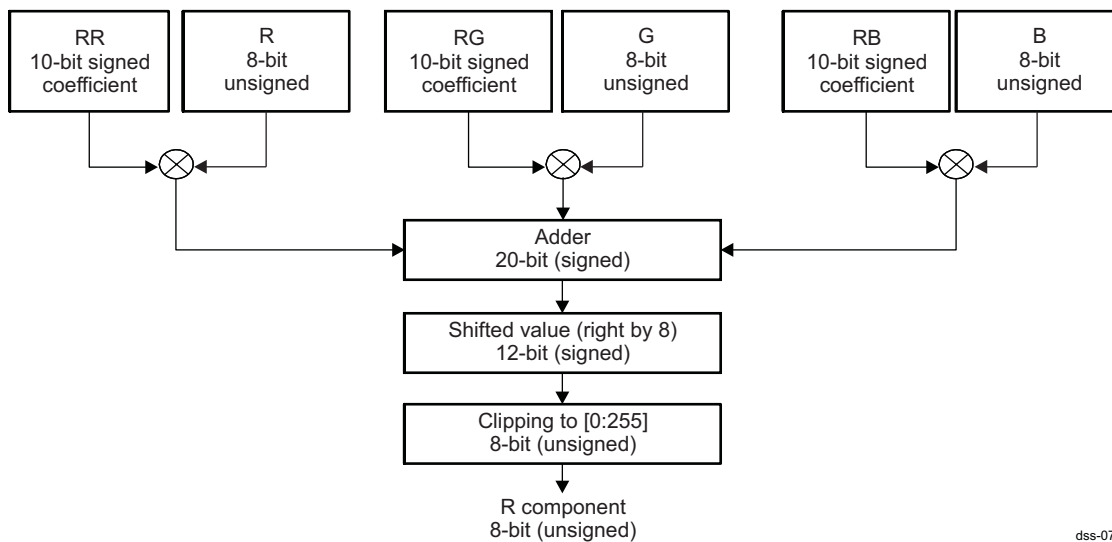

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in [Figure 15-87](#).

**Figure 15-87. Color Phase Rotation Matrix**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E076

Figure 15-88 shows the color phase rotation macro-architecture.

**Figure 15-88. Color Phase Rotation Macro Architecture**

#### 15.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).
- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

#### 15.4.2.5.2 Passive Matrix Display Dithering Logic

- **Passive matrix technology**  
After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of

the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.

- Active matrix technology

The passive matrix dithering logic is always bypassed in active displays.

---

**Note:** If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

---

#### 15.4.2.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology

The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.

- Active matrix technology

The output FIFO is bypassed in active matrix mode.

#### 15.4.2.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 15-29](#)):

- The DSS.DISPC\_CONTROL[24:23] TDMCYCLEFORMAT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC\_DATA\_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

**Table 15-29. 8-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]

**Table 15-29. 8-Bit Interface Configuration/24-Bit Mode (continued)**

Data[0]	R0[0]	G0[0]	B0[0]
---------	-------	-------	-------

#### 15.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 15-30](#) lists the maximum width depending on the TAP configuration and the pixel format.

**Table 15-30. Maximum Width Allowed**

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV422	
5	RGB16	1024
	RGB24	
	YUV422	

#### 15.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

#### 15.4.2.8 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see [Chapter 11](#), *Memory Subsystem*).

---

**Note:** It is highly recommended to use the VRFB Rotation engine when possible and not the display subsystem DMA engine for rotating frame buffer to have a good performance in the L3 interconnect and SDRAM memory efficiency.

---

The rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container) and ARGB16, RGB16, ARGB16, RGB24 (using 32-bit container) and ARGB32 and RGBA32 and YUV422 (YUV2 and YUYV). The formats not supported are BITMAP1, BITMAP2, BITMAP4 and RGB24 (using 24-bit container).

#### 15.4.2.9 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

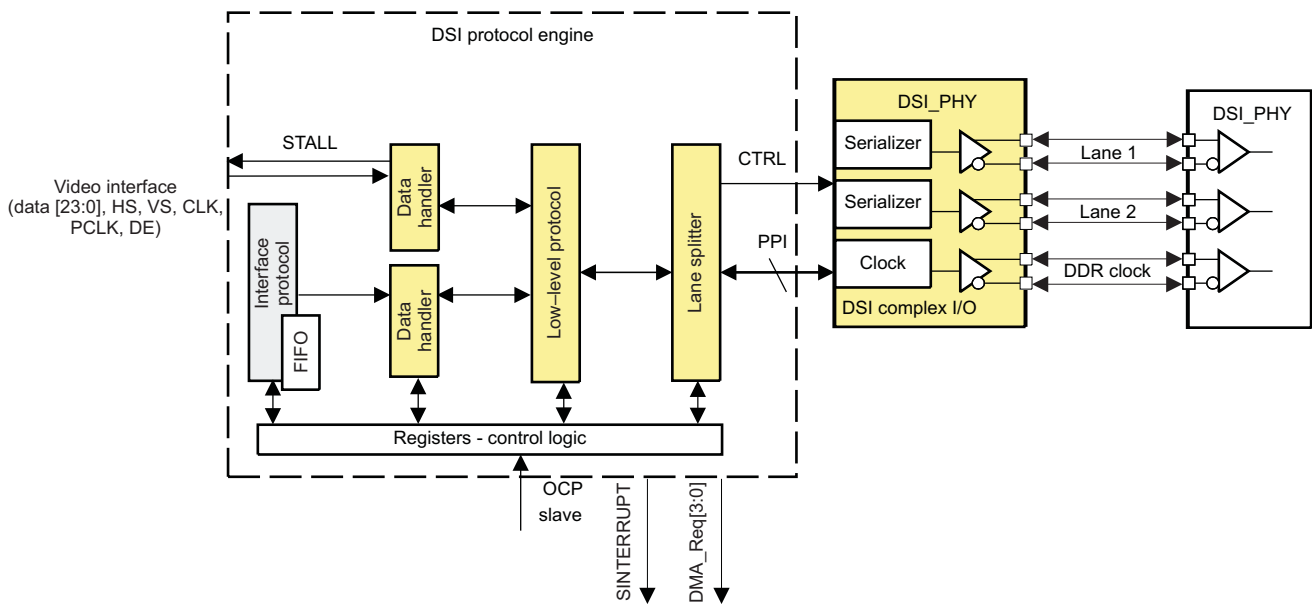

### 15.4.3 DSI Protocol Engine Functionalities

The DSI protocol engine integrates DSI interface to the display through the DSI DSI\_PHY module, L4 interconnect interface and video interface from the display controller. The DSI DSI\_PHY or complex I/O module is detailed in Section 15.4.5. The DSI Transmitter (Protocol Engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL Control module detailed in Section 15.4.4. The DSI Transmitter port can be used in video mode or/and command mode.

#### 15.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the VC ID, generates the ECC and check-sum, and splits the data into byte stream to the DSI\_PHY to be sent using the low-speed (LS) or high-speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bidirectional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. Figure 15-89 details the DSI protocol engine architecture.

Figure 15-89. DSI Protocol Engine

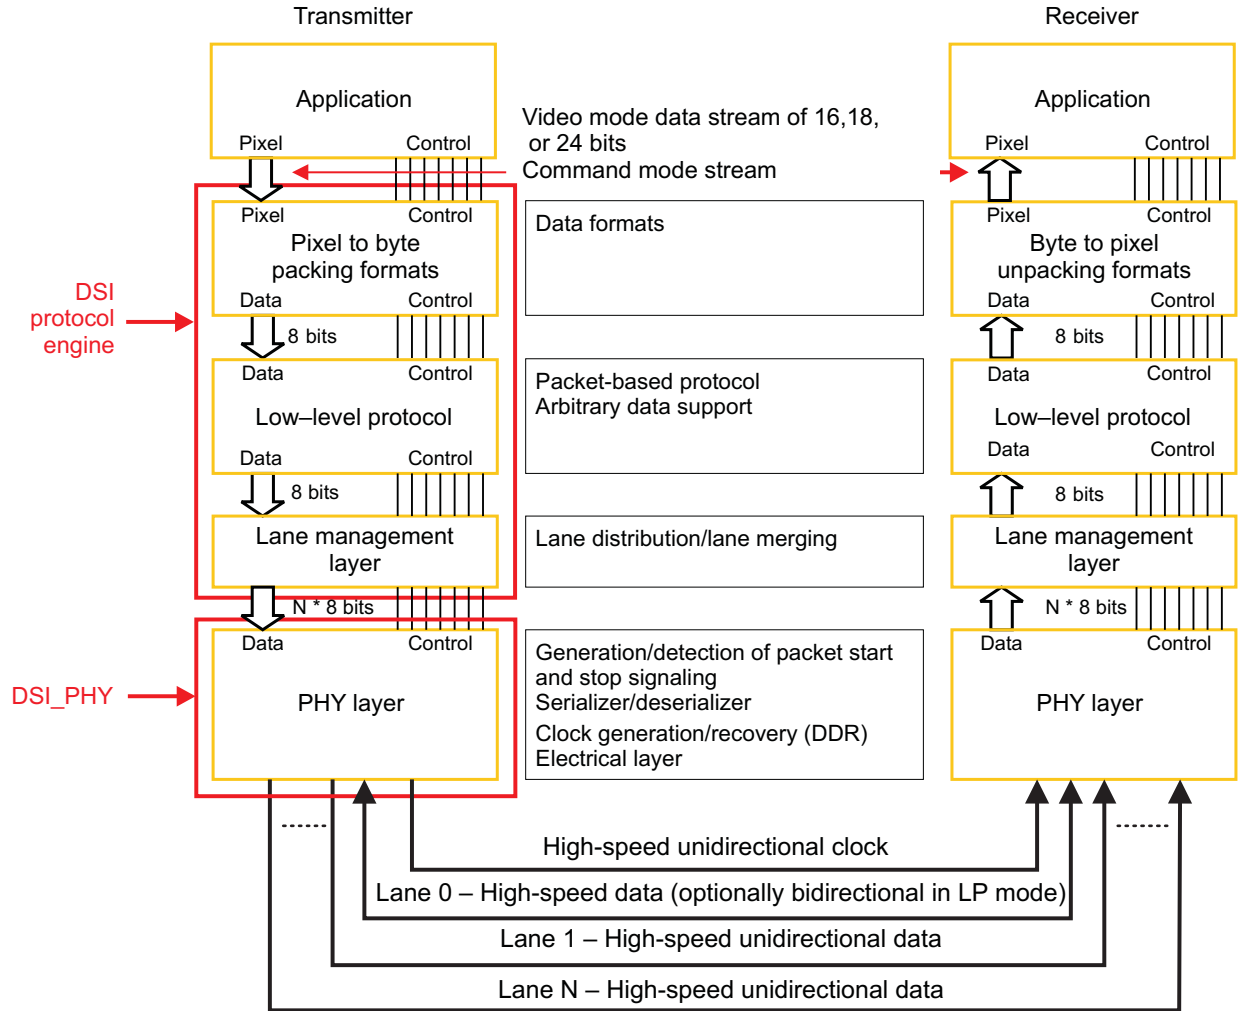

dss-166

**Note:** The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.DSI\_COMPLEXIO\_CFG1 register.

The DSI serial interface is a bidirectional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 800 Mbps per channel. The speed of the link can be software configured only when the DSI\_PHY is in stop state or in ULPS.

Figure 15-90 shows the DSI transmitter/receiver high-level data flow.

**Figure 15-90. DSI Transmitter/Receiver Data Flow**

dss-167

### 15.4.3.2 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit: This bit can be programmed only when the interface is disabled (that is, DSS.DSI\_CTRL[0] IF\_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSS.DSI\_CLK\_CTRL[12:0] LP\_CLK\_DIVISOR bit field. The LP clock generated from DSI functional clock should be in the range of 20 MHz down to 32 KHz. The duty cycle should be 50/50 (tolerance of 45/55 for maximum value). LP clock frequency visible on the pads (DP xor DN) is half the frequency of TxClkEsc.

The DSS.DSI\_CLK\_CTRL[20] LP\_CLK\_ENABLE bit is used to enable or disable the clock. When disabled, the value of DSS.DSI\_CLK\_CTRL[12:0] LP\_CLK\_DIVISOR bit field is ignored and does not have to be programmed by software users.

15.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 15-91 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 15-31 lists the LP to HS timing parameters.

Figure 15-91. LP to HS Timing

dss-325

Table 15-31. LP to HS Timing Parameters

Timing	Description	Register
T <sub>LPX</sub>	Length of any low-power state period. The value set in DSI_PHY_CFG1[22:16] TLPX_HALF bit field is half of the T <sub>LPX</sub> .	DSI_PHY_CFG1[22:16] TLPX_HALF
T <sub>CLK-PREPARE</sub>	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_CFG2[7:0] TCLK_PREPARE
T <sub>CLK-ZERO</sub>	Time to drive the CLK lane to HS-0 state before starting the clock	DSI_PHY_CFG1[7:0] TCLK_ZERO
T <sub>CLK-PRE</sub>	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode T <sub>CLK-PRE</sub> = DDR_CLK_PRE - T <sub>LPX</sub> - T <sub>CLK-PREPARE</sub> - T <sub>CLK-ZERO</sub>	See the MIPI DSI_PHY specification.
T <sub>HS-PREPARE</sub>	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_CFG0[31:24] THS_PREPARE
T <sub>HS-ZERO</sub>	Time to drive the data lane to HS-0 state before the synchronous sequence. T <sub>HS-ZERO</sub> = DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO - T <sub>HS-PREPARE</sub>	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO

**Table 15-31. LP to HS Timing Parameters (continued)**

Timing	Description	Register
DDR_CLK_PRE	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING[15:8] DDR_CLK_PRE
ENTER_HS_MODE_LATENCY	Time to enter into HS mode. It is critical that $ENTER\_HS\_MODE\_LATENCY = 1 + DIVROUNDUP(2 * TLPX\_HALF, 4) + DIVROUNDUP(THS\_PREPARE, 4) + DIVROUNDUP(THS\_PREPARE\_THS\_ZERO - THS\_PREPARE + 3, 4)$ <sup>(1)</sup>	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY

(1) The formula  $DIVROUNDUP(value, div)$  is equivalent to  $ROUNDUP(value/div)$ .

**15.4.3.2.2 Timing Parameters for an HS to LP Transaction**

Figure 15-92 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Figure 15-92 lists the HS to LP timing parameters.

**Figure 15-92. HS to LP Timing**

dss-326

**Table 15-32. HS to LP Timing Parameters**

Timing	Description	Register
$T_{HS-EOT}$	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes: 1 data lane = 4 DDR clocks 2 data lanes = 2 DDR clocks	
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of a HS transmission burst	DSI_PHY_CFG0[15:8] THS_TRAIL
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_CFG0[7:0] THS_EXIT
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	See the MIPI DSI-PHY specification.
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of a HS transmission burst	DSI_PHY_CFG1[15:8]TCLK_T RAIL
DDR_CLK_POST	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $DDR\_CLK\_POST \geq T_{HS-TRAIL} + T_{HS-EXIT} + T_{CLK-POST}$	DSI_CLK_TIMING[7:0] DDR_CLK_POST
EXIT_HS_MODE_LATENCY	Time to exit in HS mode. It is critical that $EXIT\_HS\_MODE\_LATENCY = DIVROUNDUP((T_{HS-TRAIL} + T_{HS-EXIT}, 4) + 1 + T_{HS-EOT}^{(1)})$	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY

(1) The formula  $DIVROUNDUP(value, div)$  is equivalent to  $ROUNDUP(value/div)$ .

#### 15.4.3.2.3 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the VCs sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI\_CLK\_CTRL[17:16] LP\_CLK\_NULL\_PACKET\_SIZE bit field. The header value depends on the VC ID and the size of the payload as detailed in Table 15-33 and Table 15-34.

**Table 15-33. Extra NULL Packet Header**

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F
	1		0x1		0x05
	2		0x2		0x39
	3		0x3		0x23
0x2	0	0x89	0x0		0x10
	1		0x1		0x0A
	2		0x2		0x36
	3		0x3		0x2C
0x3	0	0xC9	0x0	0x06	
	1		0x1	0x1C	
	2		0x2	0x20	

**Table 15-33. Extra NULL Packet Header (continued)**

Virtual Channel ID	Payload size ( <a href="#">DSI_CLK_CTRL</a> [17:16] <a href="#">LP_CLK_NULL_PACKET_SIZE</a> )	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
	3		0x3		0x3A

**Table 15-34. Extra NULL Packet Payload**

Payload size ( <a href="#">DSI_CLK_CTRL</a> [17:16] <a href="#">LP_CLK_NULL_PACKET_SIZE</a> )	Payload (1st byte)	Payload (2nd byte)	Payload (3rd byte)	Payload (CRC) LSB	Payload (CRC) MSB
0	NA	NA	NA	0xFF	0xFF
1	0	NA	NA	0x87	0x0F
2	0	0	NA	0xB8	0xF0
3	0	0	0	0x33	0x39

**Notes:**

- In [Table 15-33](#) and [Table 15-34](#), both ECC and checksum are enabled.
- NA means not available.

**15.4.3.3 DSI Transfer Modes**

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels must be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that TE should be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

**15.4.3.3.1 Video Mode**

The video mode refers to the MIPI DPI standard. The sync events and pixels should be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers.

**15.4.3.3.2 Command Mode**

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 15.4.3.3.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

**Note:** In DSI command mode, the display controller must be configured in stall mode by setting the [DSS.DISPC\\_CONTROL](#)[11] STALLMODE bit to 1.

The [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) registers are used for the header of long packets, the [DSS.DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) registers are used for the short packets.

The error correction code (ECC) can be provided while writing the ECC value directly into the [DSS.DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#) and [DSS.DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) registers. The [DSS.DSI\\_VCn\\_CTRL](#)[8] ECC\_TX\_EN bit indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of

synchronization short packets for video mode, since the hardware generates the short packets without using DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER registers, if the DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit is set to 1, the ECC is calculated otherwise the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD registers are used. Each 32-bit PAYLOAD data is written into the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers is used to determine the number of bytes to be sent using the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD registers. The write into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER registers is required before accessing the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register. The hardware should be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register. The hardware takes into account the write into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register only if the VC is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register is used. The video port pixels are used for the payload. When the pixel data is coming from the display controller video port, the DSI protocol can add a DCS command byte between the packet header and pixel data by setting the DSS.DSI\_CTRL[24] DCS\_CMD\_ENABLE bit to 0x1. The value will be either 0x2c (write\_memory\_start) by setting the DSS.DSI\_CTRL[25] DCS\_CMD\_CODE bit to 0x1, or 0x3c (write\_memory\_continue) by setting the DSS.DSI\_CTRL[25] DCS\_CMD\_CODE bit to 0x0.

When transmitting RGB 16-BPP data, the DSS.DSI\_CTRL[26] RGB565\_ORDER bit must be set to 0x1 to maintain the pixel byte order as in video mode .

A 2-line ping-pong buffer is implemented to allow the DSI protocol engine to store incoming pixels from the display controller through the video port while sending the DSI formatted frame to the DSI\_PHY. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 \*32 bits). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

The ping-pong buffer status can be checked by the DSI\_VCn\_CTRL[14] PP\_BUSY bit.

- When PP\_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, the user cannot update a new header.
- When PP\_BUSY equals 0, at least one line buffer is empty; therefore, the user can update a new header. PP-BUSY is then set to 0x1. If both line buffers are empty, the user can write two headers, one following the other. PP\_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after second header is written.

An IRQ is available to allow software to update header on events. The IRQ is enabled by setting the DSI\_VCn\_IRQENABLE[8] PP\_BUSY\_CHANGE\_IRQ bit to 0x1, and its status is accessible on the DSI\_VCn\_IRQSTATUS[8] PP\_BUSY\_CHANGE\_IRQ bit.

#### **15.4.3.3.3 Video + Command Modes**

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels should be provided on the L4 interconnect only.

#### **15.4.3.3.4 Burst Modes**

- Frequency-burst mode The frequency-burst mode is used to reduce the high-speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being

received on the video port.

- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

#### 15.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

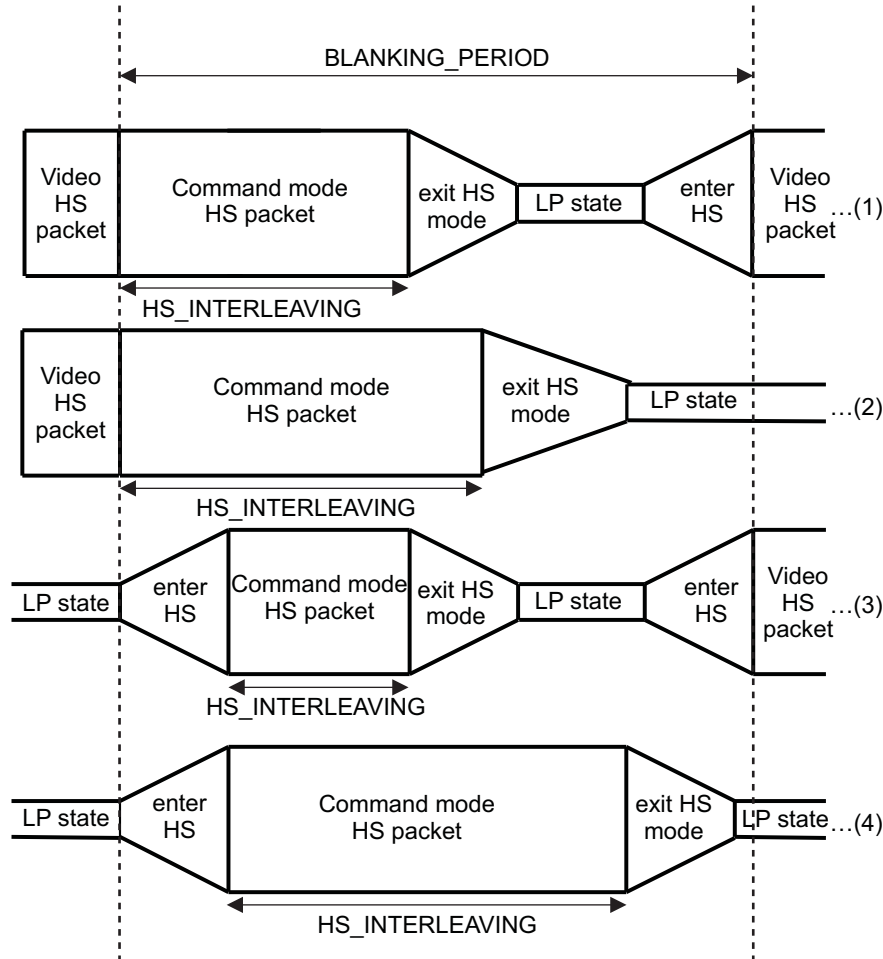

#### 15.4.3.3.5.1 HS Command Mode Interleaving Programming Model

Figure 15-93 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL\_HS\_INTERLEAVING[31:16] [DSI\\_VM\\_TIMING6](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP\_HS\_INTERLEAVING[7:0] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP\_HS\_INTERLEAVING[15:8] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA\_HS\_INTERLEAVING[23:16] [DSI\\_VM\\_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 15-93. HS Command Mode Interleaving

dss-327

**Note:** For calculations and equations, the following abbreviations are used: EXIT\_CLK\_HS\_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.  
 $EXIT\_CLK\_HS\_MODE = T_{CLK-TRAIL} + TH_{S-EXIT}$

For the following equations, BLANKING\_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS\_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL\_HS\_INTERLEAVING, HSA\_HS\_INTERLEAVING, HBP\_HS\_INTERLEAVING, or HFP\_HS\_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr\_clk\_always\_on.

- ddr\_clk\_always\_on = 1: Clock lane is always active.
- ddr\_clk\_always\_on = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - ddr\_clk\_always\_on = 1  
 $HS\_INTERLEAVING = BLANKING\_PERIOD - (EXIT\_HS\_MODE\_LATENCY + \max\{ENTER\_HS\_MODE\_LATENCY, 2\} + 1)$
  - ddr\_clk\_always\_on = 0  
 $HS\_INTER1 = BLANKING\_PERIOD - (EXIT\_HS\_MODE\_LATENCY + \max\{ENTER\_HS\_MODE\_LATENCY, 2\} + 1)$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + \text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
  - $\text{ddr\_clk\_always\_on} = 1$ 

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 3)$$
  - $\text{ddr\_clk\_always\_on} = 0$ 

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 3)$$

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + 3)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - $\text{ddr\_clk\_always\_on} = 1$ 

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
  - $\text{ddr\_clk\_always\_on} = 0$ 

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + \text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - $\text{ddr\_clk\_always\_on} = 1$ 

$$\text{HS\_INTERLEAVING} = \text{BLANKING\_PERIOD} - (\text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + 3)$$
  - $\text{ddr\_clk\_always\_on} = 0$ 

$$\text{HS\_INTER1} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{EXIT\_HS\_MODE\_LATENCY} + 3)$$

$$\text{HS\_INTER2} = \text{BLANKING\_PERIOD} - (\text{DDR\_CLK\_PRE} + \text{ENTER\_HS\_MODE\_LATENCY} + \text{DDR\_CLK\_POST} + \text{EXIT\_CLK\_HS\_MODE} + 1)$$

$$\text{HS\_INTERLEAVING} = \min\{\text{HS\_INTER1}, \text{HS\_INTER2}\}$$

#### 15.4.3.3.5.2 LP Command Mode Interleaving Programming Model

Figure 15-94 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in LP command mode packets.

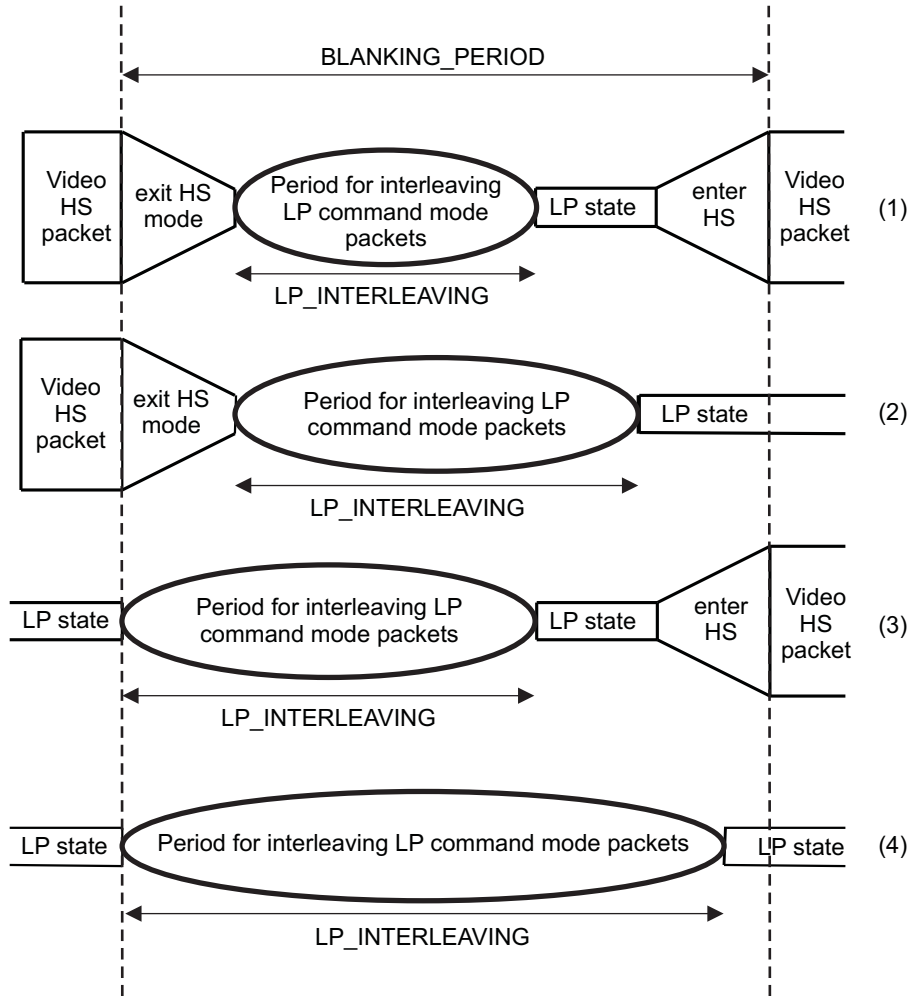

- BL\_LP\_INTERLEAVING bit field [DSI\\_VM\\_TIMING6\[15:0\]](#) defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during a BLLP gap.
- HBP\_LP\_INTERLEAVING bit field [DSI\\_VM\\_TIMING5\[7:0\]](#) defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during an HBP gap.
- HFP\_LP\_INTERLEAVING bit field [DSI\\_VM\\_TIMING5\[15:8\]](#) defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- HSA\_LP\_INTERLEAVING bit field [DSI\\_VM\\_TIMING5\[23:16\]](#) defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

Figure 15-94. LP Command Mode Interleaving

dss-328

For the following equations, **BLANKING\_PERIOD** represents the BLLP, HSA, HBP, or HFP blanking periods. The **LP\_INTERLEAVING** period represents the maximal period in LP command mode packets. Its value is set in the **BL\_LP\_INTERLEAVING**, **HSA\_LP\_INTERLEAVING**, **HBP\_LP\_INTERLEAVING**, or **HFP\_LP\_INTERLEAVING** registers, depending on the blanking type.

**ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP** represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the **LP\_INTERLEAVING** value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the **LP\_INTERLEAVING** value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + \max\{\text{ENTER\_HS\_MODE\_LATENCY}, 2\} + 1)$$
- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\text{EXIT\_HS\_MODE\_LATENCY} + 1)$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.  

$$\text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} = \text{BLANKING\_PERIOD} - (\max\{$$

ENTER\_HS\_MODE\_LATENCY, 2} + 1)

- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP = BLANKING\_PERIOD – 1

After finishing Step 1, the time period available for LP interleaving is known:

$$T_{lp\_available} = \text{ALLOWED\_HSBYTE\_CLOCKS\_FOR\_LP} * T_{TxByteClkHS}$$

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$LP\_INTERLEAVING < \left[ \frac{T_{lp\_available} - 8 * T_{hsbyte\_clk} - 5 * T_{dsif\_clk}}{T_{txclkesc}} - 26 \right]$$

dss-E124

TxByteClkHS: Period of HS byte clock of DSI\_PHY module

Tdsif\_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

#### 15.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO\_CLK\_ICG to gate the L3 interface clock (L3\_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3\_ICLK clock at DSI complex I/O level, set the DSS.DSI\_CLK\_CTRL[14] CIO\_CLK\_ICG bit to 1.

#### 15.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users should take into account the delay in processing the transfer of the data from/to the slave port to/from the module.

##### 15.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map should be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSI\_PHY\_CFG0 and DSS.DSI\_PHY\_CFG1) is done only when the DISPC\_UPDATE\_SYNC signal from the display controller is active and the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC\_UPDATE\_SYNC signal is asserted, the DSS.DSI\_COMPLEXIO\_CFG1[30] GObit is reset by hardware and there is no SCP transfer.
  - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is reset by hardware.
  - If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI\_COMPLEXIO\_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer should complete prior to start the update of shadowing registers.

- When unsetting the DSS.DSI\_COMPLEXIO\_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished

---

**Note:** When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI complex I/O are returned.

---

#### 15.4.3.5.2 *Busy Signal*

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS\_L3\_ICLK clock.

#### 15.4.3.6 **Power Control**

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

### 15.4.3.6.1 Complex I/O Power Control Commands

#### 15.4.3.6.1.1 Complex I/O Power Control Commands

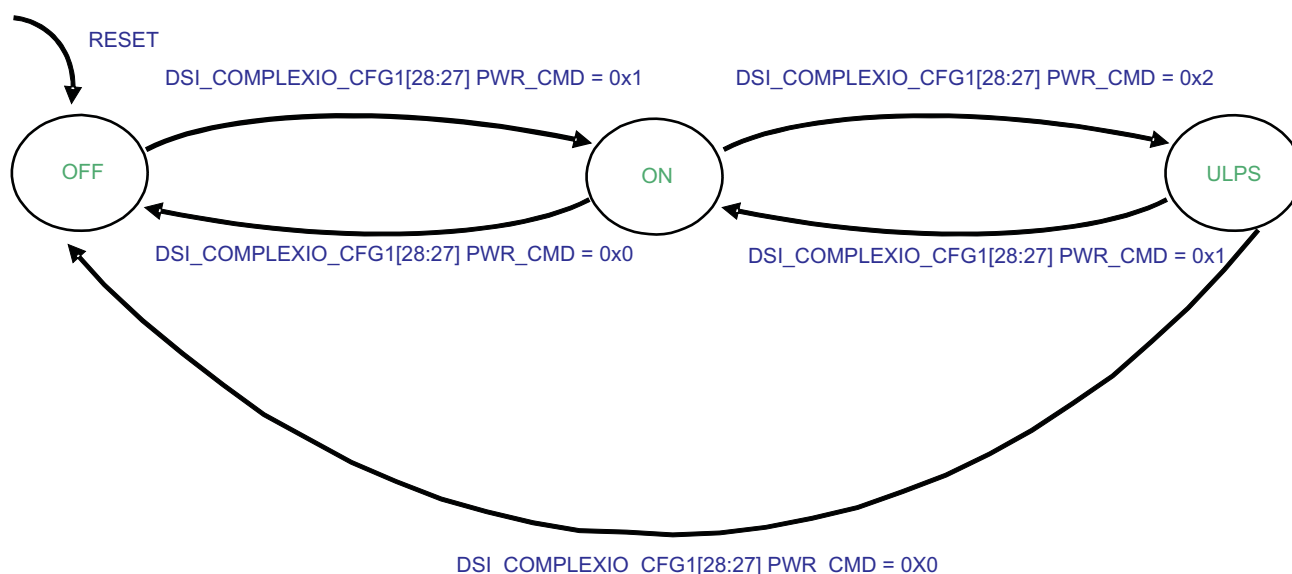

The DSI complex I/O can be set into three modes:

- OFF: In this power state, the complete DSI\_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI\_PHY circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultralow-power state should only be used when all the three lanes are in ULPS (transmit or receive).

#### 15.4.3.6.1.2 Complex I/O Power FSM

Figure 15-95 describes the power control FSM to control the power state of the complex I/O.

**Figure 15-95. Complex I/O Power FSM**

dss-169

The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users should set the DSS.DSI\_COMPLEXIO\_CFG1[28:27] PWR\_CMD bit field to ask for a state change. The allowed transitions are: OFF -> ON and ON -> ULP and ULP -> OFF. The DSS.DSI\_COMPLEXIO\_CFG1[26:25] PWR\_STATUS bit field gives a status on the current state of the DSI complex I/O.

#### CAUTION

- In automatic mode, the software should ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, users should ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot\_ALL0\_IRQ interrupt can be used by software users to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP status exit sequence (refer to [Section 15.4.3.7.1](#) for details).

### 15.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

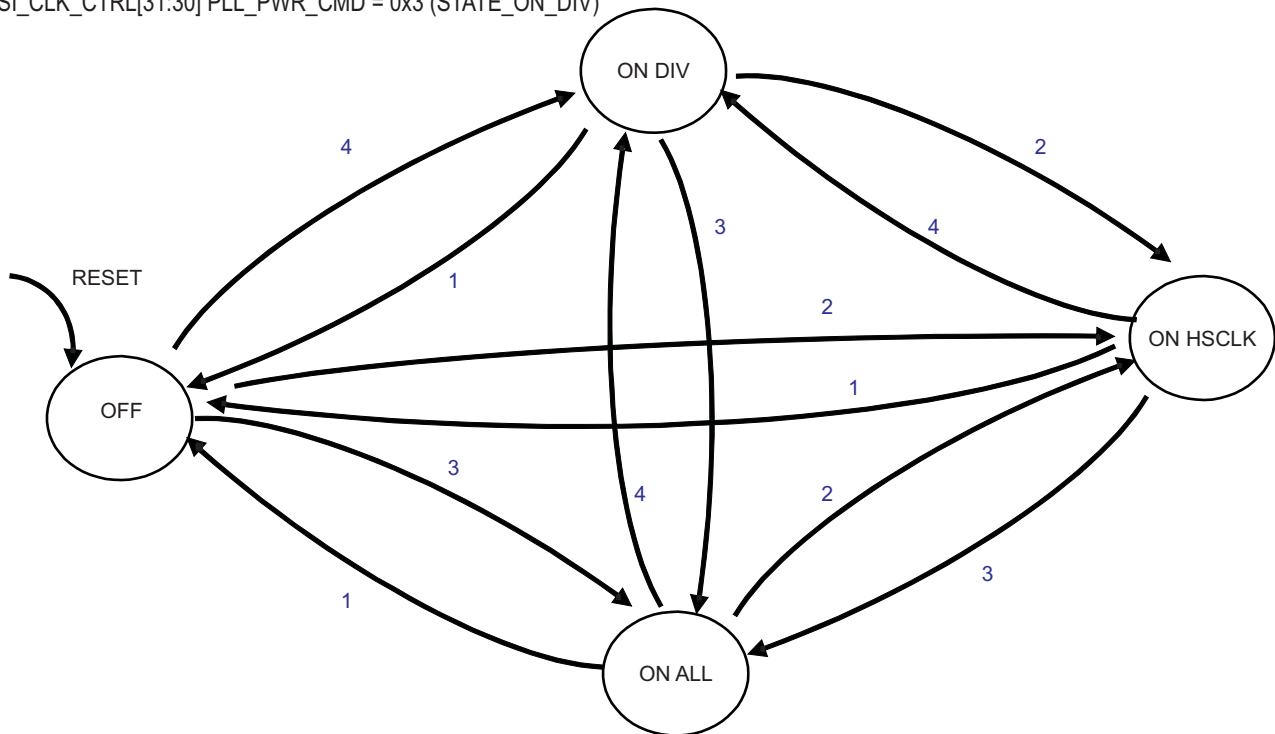

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS\_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS\_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS\_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

#### 15.4.3.6.2.1 DSI-PLL Power FSM

Figure 15-96 shows the DSI PLL power FSM.

Figure 15-96. DSI PLL Power FSM

- 1 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x0 (STATE\_OFF)
- 2 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x1 (STATE\_ON\_HSCLK)
- 3 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x2 (STATE\_ON\_ALL)
- 4 = DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD = 0x3 (STATE\_ON\_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSCLK controls the state transition of the DSI PLL control module. Software users should set the DSS.DSI\_CLK\_CTRL[31:30] PLL\_PWR\_CMD bit field to ask for a state change. The DSS.DSI\_CLK\_CTRL[29:28] PLL\_PWR\_STATUS bit field gives a status on the current state of the DSI PLL controller.

**Note:** In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL

SYSRESET signals can be forced by the DSI PLL controller module by setting DSS.DSI\_PLL\_CONTROL[4] DSI\_HSDIV\_SYSRESET and DSS.DSI\_PLL\_CONTROL[3] DSI\_PLL\_SYSRESET bits, respectively. By setting these bits to 1, the SYSRESET signal is forced active (module is forced to reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

#### 15.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI Protocol engine does not need to use the high-speed transfer mode (HS mode) and PLL HS output (HS\_CLK clock) can be stopped. The following conditions must also be met when DISPC\_UPDATE\_SYNC may be generated by the display controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI\_CTRL[0] IF\_EN bit set to 0), the signal DSIStopClk is asserted.

The assertion of the DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
  - The DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit must be reset to 0 and no HS data transfer should be on going or already scheduled
  - No VC active in video mode. No VC using the video mode is enabled; if the VC is enabled, the mode is command mode only (that is, DSS.DSI\_VCn\_CTRL[0] VC\_EN bit set to 1 and DSS.DSI\_VCn\_CTRL[4] MODE bit set to 0)
  - No command mode requiring high-speed transfer (one or more VCs using command mode can be active)
  - Or DSS.DSI\_CTRL[0] IF\_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI\_CTRL[0] IF\_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required anymore).
- One video mode VC active
- At least one VC in command mode requiring high-speed transfer
- The DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit is set to 1 by software users (the DSS.DSI\_CTRL[0] IF\_EN bit should be reset to 0 for updating the DDR\_CLK\_ALWAYS\_ON bit value)

The automatic assertion/deassertion is enabled by using the DSS.DSI\_CLK\_CTRL[18] HS\_AUTO\_STOP\_ENABLE bit.

The manual mode can be used by setting/resetting the DSS.DSI\_CLK\_CTRL[19] HS\_MANUAL\_STOP\_CTRL bit to assert/deassert the DSIStopClk signal.

### 15.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 15-97 shows the DSI PLL HS clock FSM.

Figure 15-97. DSI PLL HS Clock FSM

dss-171

When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI\_PHY) before TxByteClkHS is stopped. This latency must be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI\_STOPCLK\_TIMING[7:0] DSI\_STOPCLK\_LATENCY bit field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI\_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

#### CAUTION

The programmed value in the DSS.DSI\_STOPCLK\_TIMING[7:0] DSI\_STOPCLK\_LATENCY bit field must be greater than  $((3 \times L3\_ICLK \text{ period}) + (5 \times CLKIN4DDR \text{ period})) / (\text{DSI\_FCLK period})$ .

### 15.4.3.7 Timers

**Note:** Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

#### 15.4.3.7.1 Twakeup Timer

The  $T_{WakeUp}$  timer is not implemented in the DSI protocol engine. The software must use a general-purpose (GP) timer to handle this. This timer is used for existing ULP status mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI\_COMPLEXIO\_IRQSTATUS ULPSACTIVENOT\_ALLi\_IRQ bit fields ( $i = 0, 1$ ).

3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

---

**Note:** The minimum time for the wake-up period is 1 ms.

---

To enter ULPS mode for clock lane, TxUlpsClk state should be change to active state. To enter ULPS mode for data lane, TxRequestEsc state should be changed to active state (TxUlpsEsc as well if it is not in active state already).

#### 15.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). [Figure 15-98](#) describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

dss-172

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO bit to 1. Asserting the FORCE\_TX\_STOP\_MODE\_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP\_STATE\_COUNTER\_IO, Stop\_State\_x4\_IO, Stop\_State\_x16\_IO field DSI\_TIMING1[15:0]. The FORCE\_TX\_STOP\_MODE\_IO bit is reset by hardware when the time is reached.

This bit can be reset by software.

The calculation of the number of DSI\_FCLK cycles assertion period is defined by:

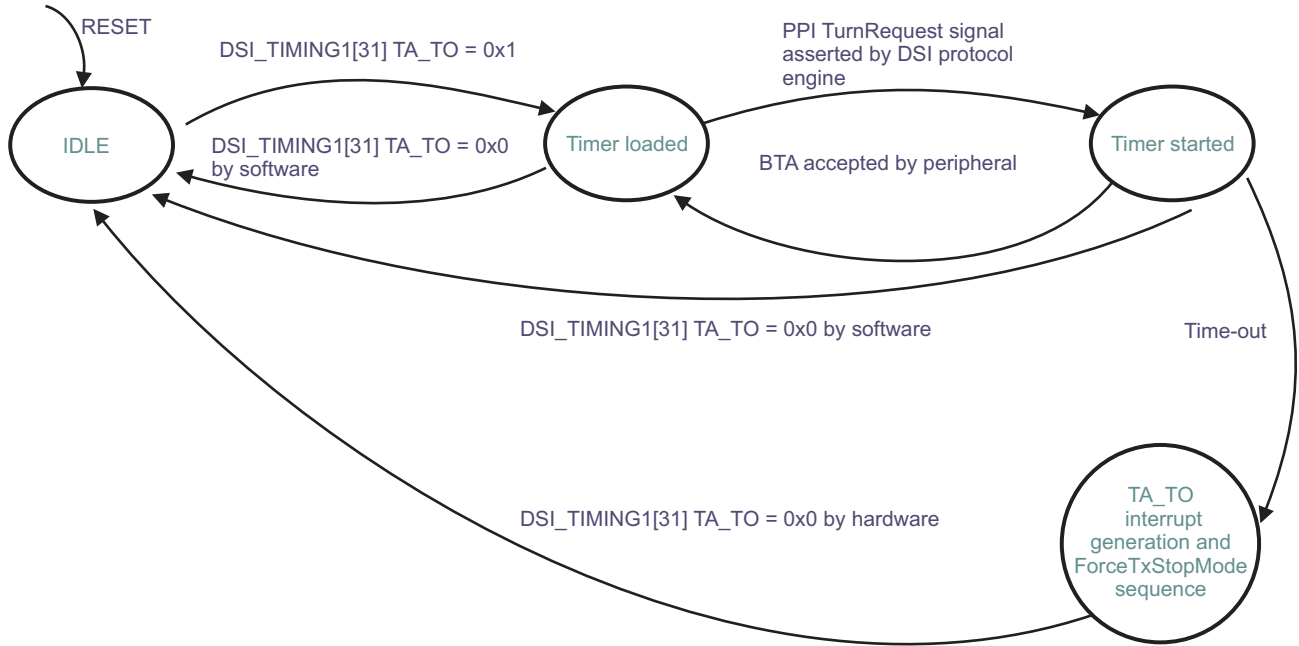

$$\text{Total period in DSI\_FCLK cycles} = \text{DSI\_TIMING1}[12:0] \text{ STOP\_STATE\_COUNTER\_IO} \times ((\text{DSI\_TIMING1}[14] \text{ STOP\_STATE\_X16\_IO} \times 15) + 1) \times ((\text{DSI\_TIMING1}[13] \text{ STOP\_STATE\_X4\_IO} \times 3) + 1)$$

#### 15.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes can not be used in the reverse direction to receive data from the DSI receiver. [Figure 15-99](#) describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 15-99. TurnRequest FSM

dss-173

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled. The DSS.DSI\_TIMING1[31] TA\_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI\_FCLK cycles:

$$\text{DSI\_TIMING1}[28:16] \text{ TA\_TO\_COUNTER} \times ((\text{DSI\_TIMING1}[30] \text{ TA\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING1}[29] \text{ TA\_TO\_X8} \times 7) + 1).$$

When the interrupt is generated, the hardware should automatically assert ForceTXStopMode in order for the DSI\_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI\_CTRL[0] IF\_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO and DSS.DSI\_CTRL[0] IF\_EN bits to be reset to 0 before starting the recovery sequence.

#### 15.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer) should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

#### 15.4.3.7.5 HS TX Timer

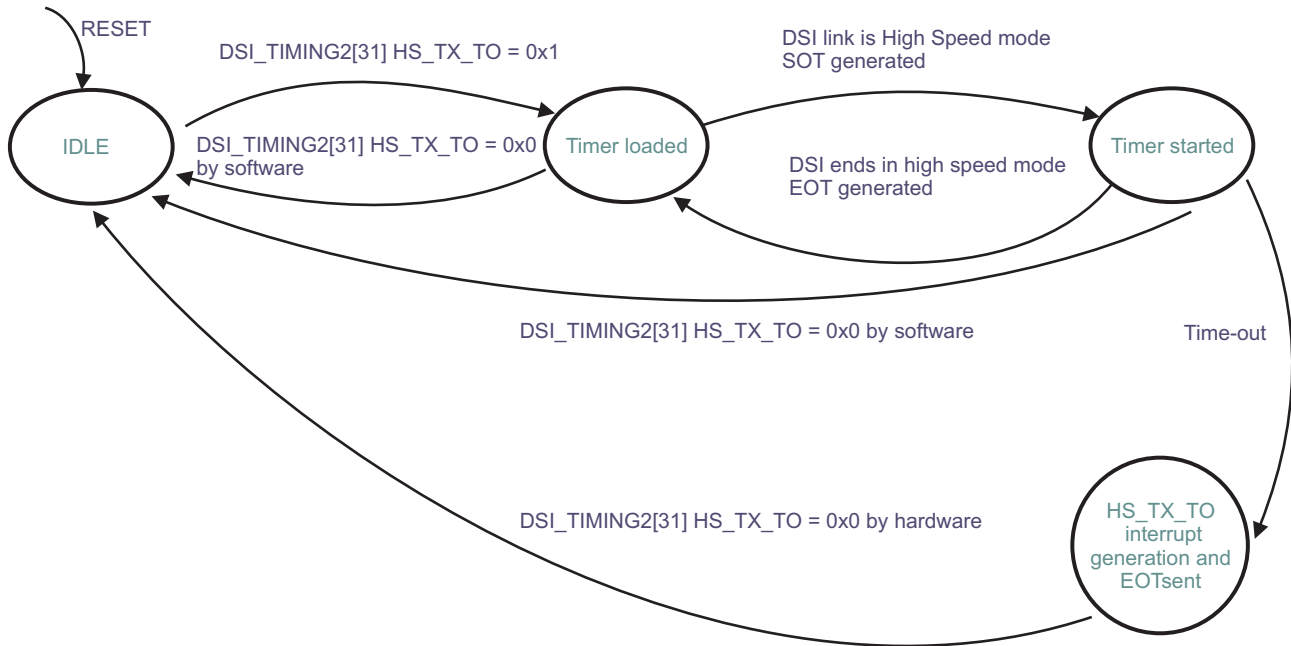

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI\_TIMING2[31] HS\_TX\_TO bit. The interrupt HS\_TX\_TO\_IRQ is generated when the timer expires. The DSS.DSI\_IRQSTATUS[14] HS\_TX\_TO\_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

$$\text{DSI\_TIMING2[28:16] HS\_TX\_TO\_COUNTER} \times ((\text{DSI\_TIMING2[30] HS\_TX\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING2[29] HS\_TX\_TO\_X8} \times 7) + 1)$$

**Figure 15-100. High-Speed TX Timer FSM**

dss-174

When the time-out occurs, the hardware should send EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI\_CTRL[0] IF\_EN bit.

The software should wait for the DSS.DSI\_CTRL[0] IF\_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

#### 15.4.3.7.6 LP RX Timer

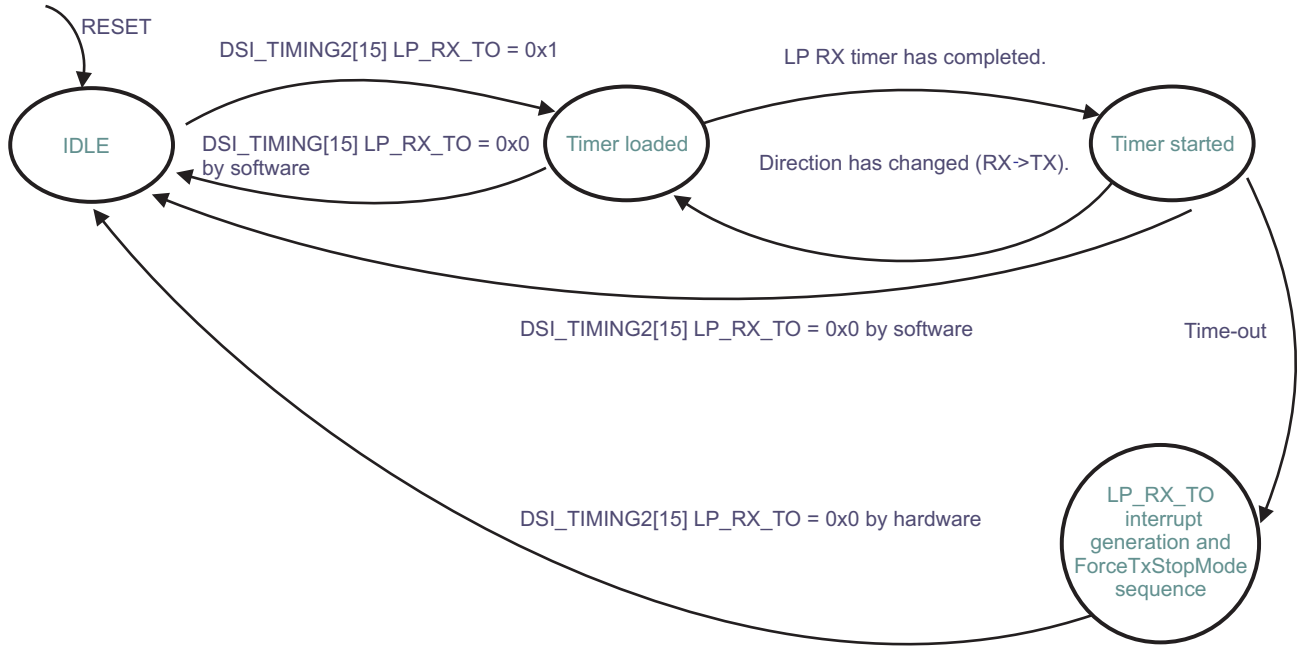

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP\_RX\_TO\_IRQ is generated when the timer expires. The DSS.DSI\_IRQSTATUS[15] LP\_RX\_TO\_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI\_TIMING2[15] LP\_RX\_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI\_FCLK cycles:

$$\text{DSI\_TIMING2[12:0] LP\_RX\_TO\_COUNTER} \times ((\text{DSI\_TIMING2[14] LP\_RX\_TO\_X16} \times 15) + 1) \times ((\text{DSI\_TIMING2[13] LP\_RX\_TO\_X4} \times 3) + 1)$$

Figure 15-101. Low-Power RX Timer FSM

dss-175

When the interrupt is generated, the hardware should automatically reset the DSS.DSI\_TIMING2[15] LP\_RX\_TO bit and then assert ForceTXStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI\_CTRL[0] IF\_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI\_TIMING1[15] FORCE\_TX\_STOP\_MODE\_IO and DSS.DSI\_CTRL[0] IF\_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI\_VcN\_CTRL[0] VC\_EN is set to 1).

### 15.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each VC ID. The VC can be enabled when DSS.DSI\_VcN\_CTRL[6] BTA\_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. When setting the DSS.DSI\_VcN\_CTRL[6] BTA\_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

#### CAUTION

The BTA should not be sent when the RX FIFO is not empty. Users should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.DSI\_VcN\_CTRL[2] BTA\_SHORT\_EN or the DSS.DSI\_VcN\_CTRL[3] BTA\_LONG\_EN bits are set to 1.

**Note:** If the DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN bit is enabled, users can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

If the DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bit is enabled, users can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

If the DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN and DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bits are both enabled, users can still set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit to send a BTA. Only one BTA is sent and the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset by hardware.

As explained previously, two modes can be used for each VC ID:

- **Automatic:** After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register).
- **Manual:** In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, users can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.DSI\_VCn\_CTRL[6] BTA\_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.DSI\_VCn\_CTRL[6] BTA\_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) users can not determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a VC in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET\_SENT\_IRQ) is provided to indicate users when the packet has been completely sent by the DSI complex I/O. The PACKET\_SENT\_IRQ can be monitored in DSI\_VCn\_IRQSTATUS[2] PACKET\_SENT\_IRQ status bit. Users can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turnaround is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent, that is, when one of the following bits is set to 1:

- DSS.DSI\_CTRL[20] BLANKING\_MODE
- DSS.DSI\_CTRL[21] HFP\_BLANKING\_MODE
- DSS.DSI\_CTRL[22] HBP\_BLANKING\_MODE
- DSS.DSI\_CTRL[23] HSA\_BLANKING\_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

#### TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA\_TO timer is started. If the direction signal is no changed according to the turn-around request, the TA\_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). Refer to [Section 15.4.3.7.3](#) for more details on the TA\_TO timer.

#### 15.4.3.9 PHY Triggers

The DSI protocol engine uses three triggers:

- Reset from host to display
- TE from display to host

- Acknowledge

These triggers are supported only for data lane #1. The reset trigger is associated with the signal TxTriggerEsc1[3]. The TE trigger is associated with the signal RxTriggerEsc1[2]. The acknowledge trigger is associated with the signal RxTriggerEsc1[1].

---

**Note:** The TX signals - TxTriggerEsc1[2], TxTriggerEsc1[1], and TxTriggerEsc1[0] - and the RX signals - RxTriggerEsc1[3], and RxTriggerEsc1[0] - are not used by DSI protocol engine.

---

#### 15.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI\_PHY to send a reset to the display. The DSS.DSI\_CTRL[5] TRIGGER\_RESET bit is set to 1 to send the trigger reset. When the software requires the trigger reset to be sent to the peripheral, the DSI protocol engine should reset its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is VC using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.DSI\_CTRL[14] TRIGGER\_RESET\_MODE.

#### CAUTION

For both reset modes, the hardware should flush the FIFOs, synchronization buffers, and line buffers before resetting the DSS.DSI\_CTRL[0] IF\_EN bit.

#### 15.4.3.9.2 Tearing Effect

The TE on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. Users are responsible for selecting the command mode for the VC using the TE feature.

The software must set and send the appropriate sequence to receive the TE trigger from the peripheral. When receiving the TE trigger, the DSI protocol engine should generate the TE\_TRIGGER\_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.DSI\_IRQENABLE[16] TE\_TRIGGER\_IRQ\_EN bit. The DSS.DSI\_IRQSTATUS[16] TE\_TRIGGER\_IRQ status bit indicates if the interrupt event has been generated.

One or multiple VCs can be synchronized using the same TE trigger. The DSS.DSI\_VCn\_TE[30] TE\_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related VC. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI\_VCn\_TE[31] TE\_START bit should be used when the automatic mode enabled by setting the DSS.DSI\_VCn\_TE[30] TE\_EN bit is not used. It allows users to start the transfer manually based on application events or based on the TE trigger interrupt (TE\_TRIGGER\_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field. The TE\_SIZE bit field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field should be set first to indicate that the following accesses to DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register should be used for TE transfer.

The data can be provided from two sources (selection by setting the DSS.DSI\_VCn\_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI\_DMA\_REQ<sub>i</sub> (where  $i = 0$  to 3) to should be asserted only when TE trigger is received or when the DSS.DSI\_VCn\_TE[31] TE\_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field have been sent on the DSI link. The VC is associated with a DMA request (from DSI\_DMA\_REQ0 to DSI\_DMA\_REQ3) by programming the number in the DSS.DSI\_VCn\_CTRL[23:21] DMA\_TX\_REQ\_NB bit field. The DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field (the check-sum value is not provided in the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI\_CTRL[13:12] LINE\_BUFFER bit field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI\_VCn\_TE[31] TE\_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field is not a multiple of the word count defined in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field).

When the transfer is completed, the value of the DSS.DSI\_VCn\_TE[15:0] TE\_SIZE bit field is equal to 0. The software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSS.DSI\_VCn\_CTRL[5] TX\_FIFO\_NOT\_EMPTY status bit.

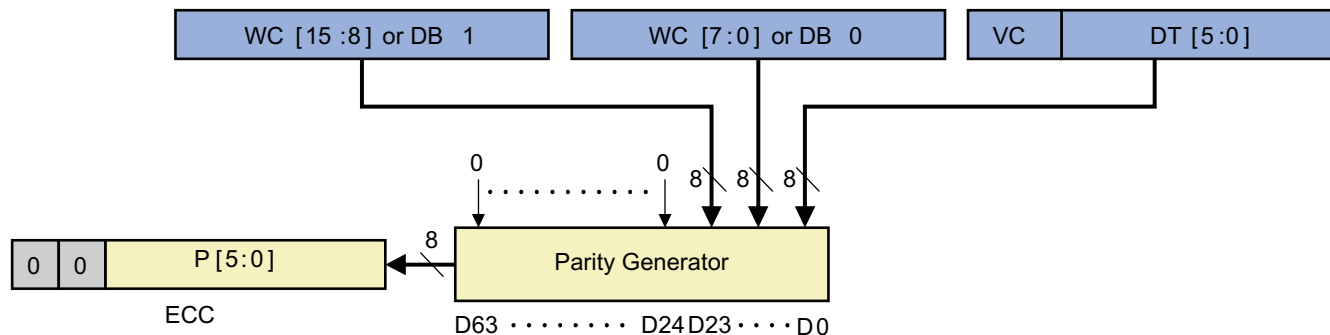

#### 15.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK\_TRIGGER\_IRQ) should be generated upon reception of the acknowledge trigger. To enable the acknowledge interrupt, set the DSS.DSI\_IRQENABLE[17] ACK\_TRIGGER\_IRQ\_EN bit to 1. When the interrupt is generated, the DSS.DSI\_IRQSTATUS[17] ACK\_TRIGGER\_IRQ status bit is set to 1.

#### 15.4.3.10 ECC Generation

Note that the DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in [Figure 15-102](#).

Figure 15-102. 64-Bit ECC Generation on TX Side

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI\_CTRL[2] ECC\_RX\_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI\_VcN\_CTRL[8] ECC\_TX\_EN bit enables/disables the ECC generation in the transmit direction

### 15.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to  $2^{16} - 1$  bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals. It is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor should disable checksum checking for received long packets from peripherals that do not support checksum generation.

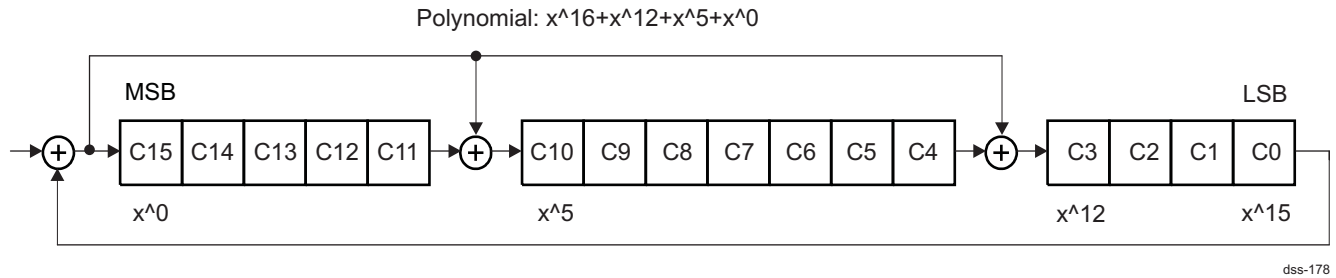

The checksum should be realized as a 16-bit CRC with a generator polynomial of  $x^{16} + x^{12} + x^5 + x^0$ . The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

Figure 15-103. Checksum Transmission

dss-177

The CRC implementation is presented in Figure 15-104. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

**Figure 15-104. 16 Bit CRC Generation Using a Shift Register**

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI\_CTRL[1] CS\_RX\_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI\_VcN\_CTRL[7] CS\_TX\_EN bit enables/disables the check-sum generation in the transmit direction

#### 15.4.3.12 End of Transfer Packet

To allow the DSI protocol (rather than the DSI\_PHY) at the display to detect the HS End Of Transfer (EOT), an EOT packet type is added. It is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the DSI\_CTRL[19] EOT\_ENABLE bit.

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more than one data lane is used, the bytes in the EOT packet are distributed across multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through the same as any other packet, but no internal decode or use is made of the EOT information.

### 15.4.4 DSI PLL Controller Functionalities

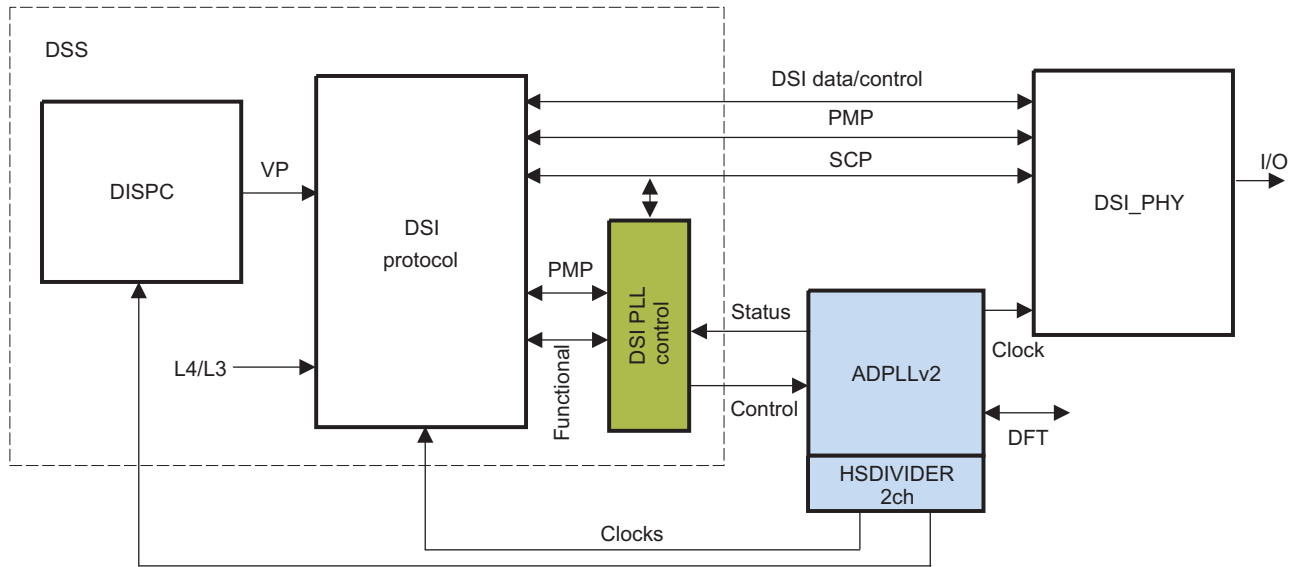

#### 15.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the display sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPPLL and HSDIVIDER modules. [Figure 15-105](#) provides an overview of the DSI PLL controller module inside the display subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

Figure 15-105. DSI PLL Controller Overview

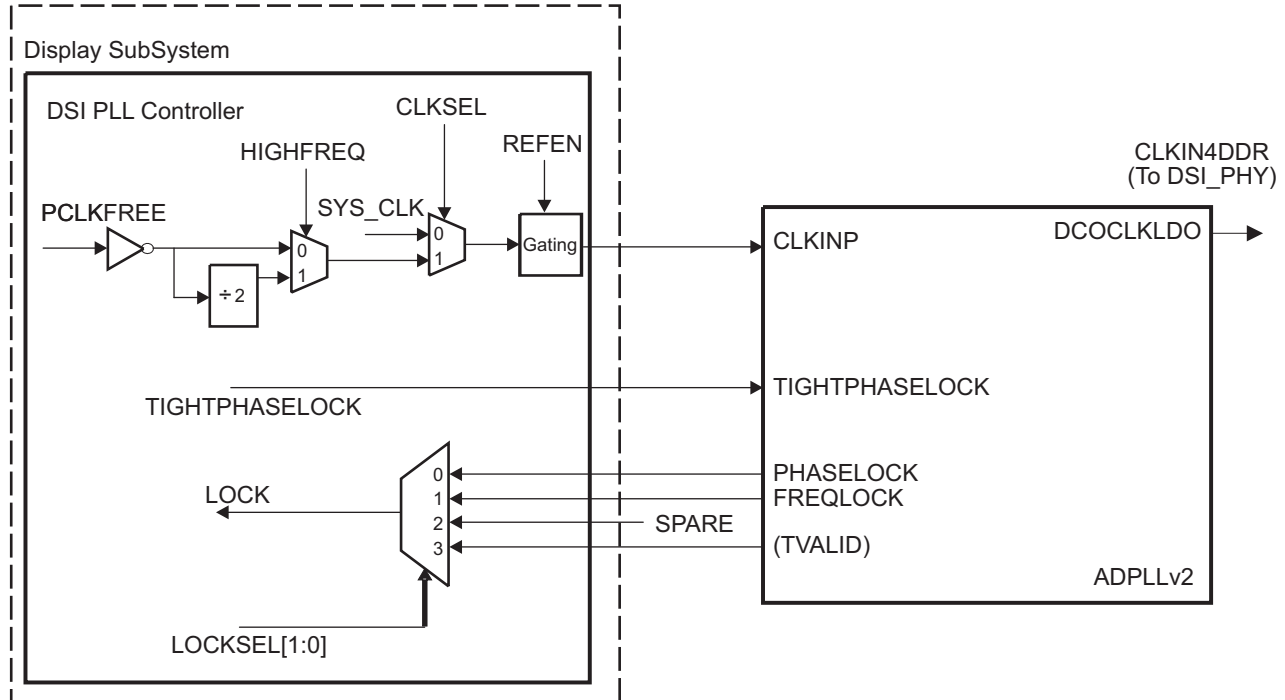

dss-179

**Note:** The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

#### 15.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLLv2 module. The pixel clock (PCLK) frequency range is 2 to 65 MHz. This may be divided by 2. This is performed by setting the DSS.DSI\_PLL\_CONFIGURATION2[12] DSI\_PLL\_HIGHFREQ bit to 1.

Figure 15-106 shows the internal DSI PLL reference diagram.

**Figure 15-106. DSI PLL Reference Diagram**

Note: PCLK is inverted as the falling edge is the reference edge and ADPLLv2 uses positive edge as reference (F/F should be positive edge clock also)

dss-180

The DSI PLL clock output corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI\_PLL\_REFCLK clock. Depending on the setting in `DSS.DSI_PLL_CONFIGURATION2[11]` `DSI_PLL_CLKSEL` bit, the reference clock can be either the `DSS2_ALWON_FCLK` provided by the PRCM or the `PCLKFREE` provided by the DISPC module.

### 15.4.4.3 DSI PLL Operations

The DSI PLL configuration signals operate according to [Table 15-35](#). [Table 15-35](#) indicates the operation when the PLL is not locked.

**Table 15-35. DSI PLL Operation Modes When Not Locked**

DSI PLL Operation Mode	Stop mode Low power <sup>(1)</sup>	Stop mode Fast Relock <sup>(1)</sup>	Idle bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
<code>DSS.DSI_PLL_CONFIGURATION2[0]</code> <code>DSI_PLL_IDLE</code>	0	0	1
<code>DSS.DSI_PLL_CONFIGURATION2[6]</code> <code>DSI_PLL_LOWCURRSTBY</code>	1	0	1
<code>DSS.DSI_PLL_CONFIGURATION1[0]</code> <code>DSI_PLL_STOPMODE</code>	1	1	X

<sup>(1)</sup> Recommended

When locked, the PLL output frequency is: Input frequency x M / (N+1) / HIGHFREQ where:

- M multiplier is programmed in `DSS.DSI_PLL_CONFIGURATION1[18:8]` `DSI_PLL_REGM` bit field.
- N divider is programmed in `DSS.DSI_PLL_CONFIGURATION1[7:1]` `DSI_PLL_REGN` bit field.
- HIGHFREQ divider by 2 is enabled by setting the `DSS.DSI_PLL_CONFIGURATION2[12]` `DSI_PLL_HIGHFREQ` bit to 1.

#### 15.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

#### **CAUTION**

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the display controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. Refer to [Section 15.4.3.5.1](#) for more details.

#### 15.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI\_PLL\_STATUS[1] DSI\_PLL\_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI\_PLL\_STATUS[2] DSI\_PLL\_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL\_LOCK\_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[7] PLL\_LOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_UNLOCK\_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[8] PLL\_UNLOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_RECAL\_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI\_IRQSTATUS[9] PLL\_RECAL\_IRQ bit. Set this bit to 1 to clear the status bit.

### 15.4.5 DSI Complex I/O Functionalities

#### 15.4.5.1 DSI Complex I/O Overview

DSI\_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support high-speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things.

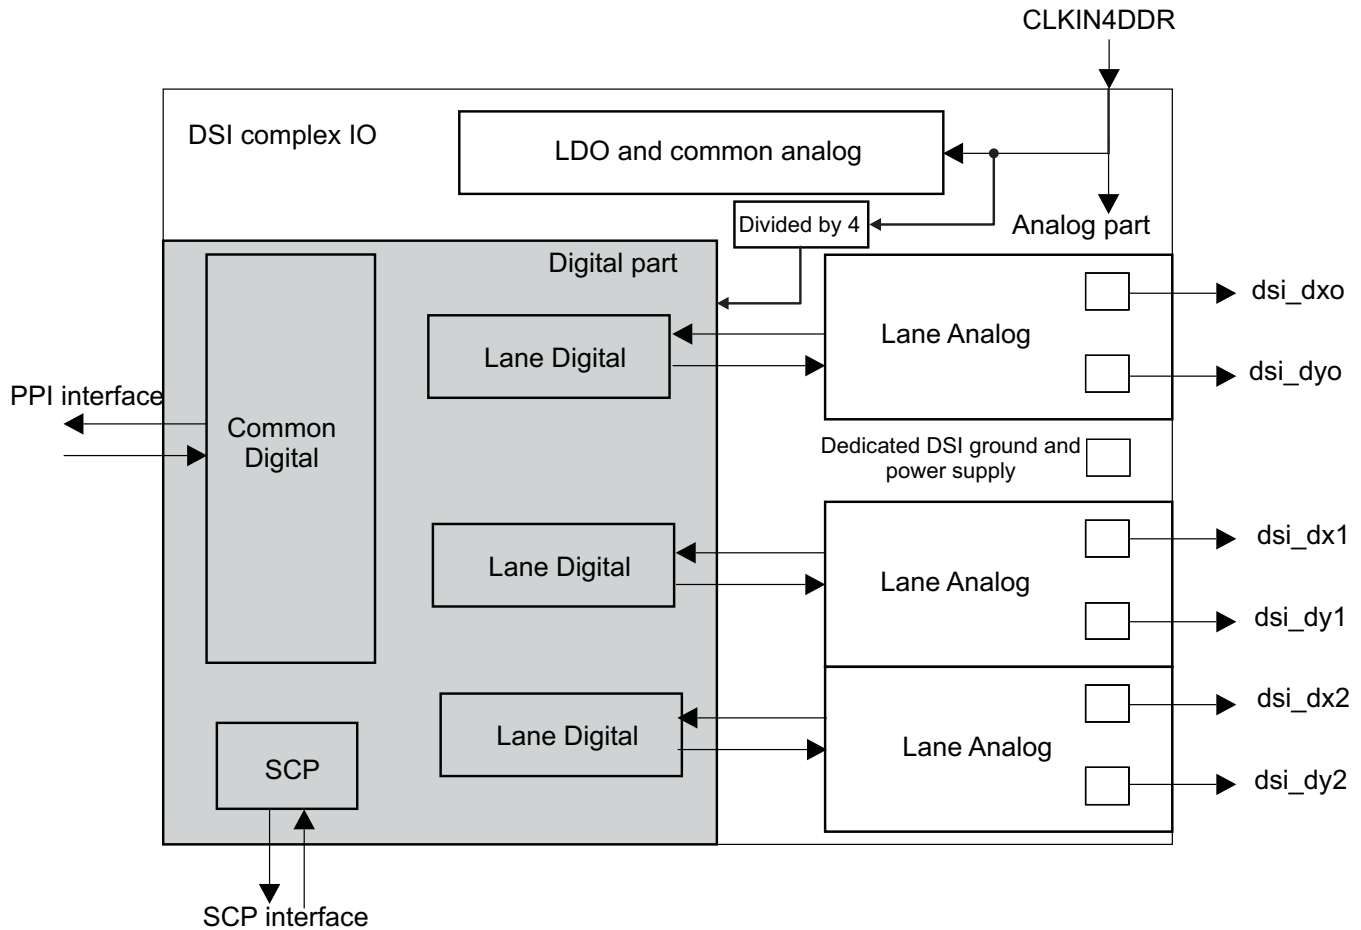

The maximum data rate supported in high-speed Mode is 800Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI\_PHY spec.

DSI\_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI\_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI\_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI\_PHY supports GPIO operation on each of the six data pins.

### 15.4.5.2 DSI Complex I/O Architecture

Figure 15-107 shows the top-level block diagram of DSI\_PHY. It has 3 lane module functions, and some common analog and digital functions. Each lane module has an analog and a digital part. The digital lane circuitry implements the protocol interface of MIPI DSI\_PHY. It interacts with the DSI protocol engine.

**Figure 15-107. DSI Complex I/O Architecture**

dss-189

The lane module analog circuit converts the digital levels to the LP and HS level signals for the link. It also converts the analog state of the link into digital levels.

For high-speed signals, the lane module analog also does the last stage untiming of HS data to obtain optimum quadrature with the HS clock.

DSI\_PHY has an internal LDO to generate 1.2V supply. This LDO requires an off-chip decoupling capacitor and hence a dedicated pin. DSI\_PHY expects a high frequency clock input in HS mode.

The clock input is required to have four times the frequency of the DDR clock, that is, twice the HS data rate. GPIO functions are supported on each dsi\_dxi and dsi\_dyi.

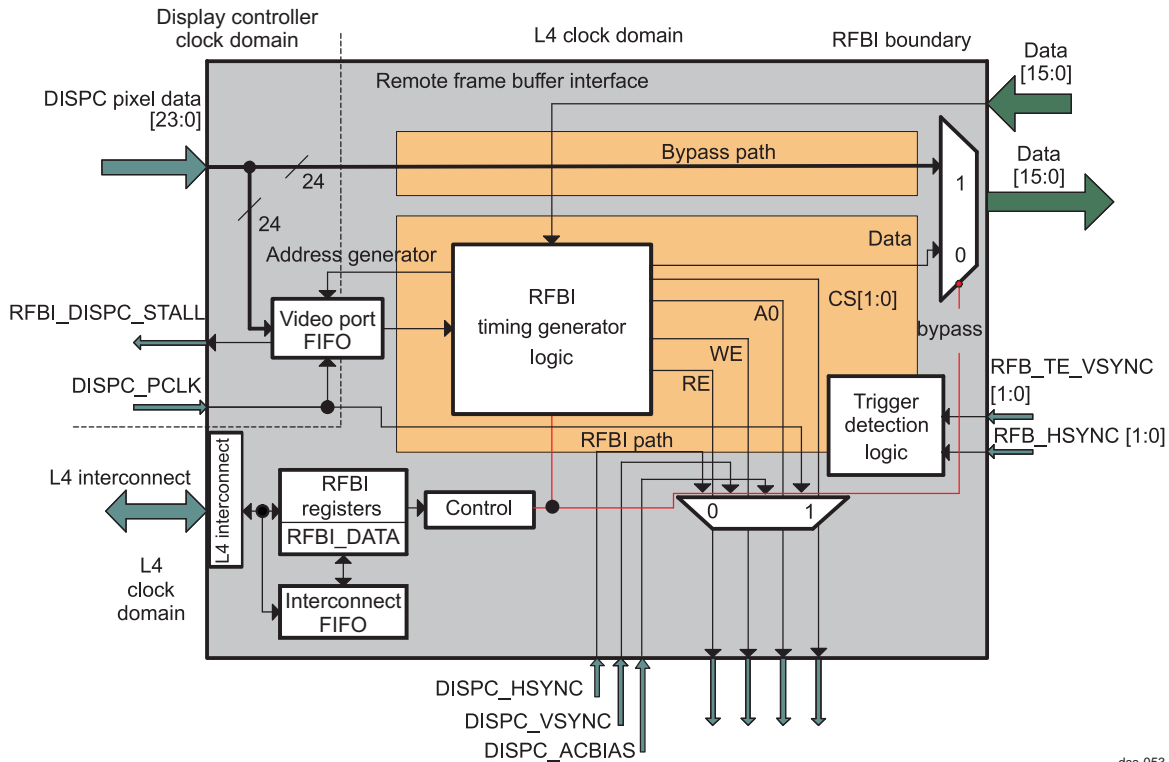

### 15.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

Figure 15-108 shows an overview of the RFBI architecture.

**Figure 15-108. RFBI Architecture Overview**

dss-053

#### 15.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 15.4.6.4, *Output Parallel Modes*, shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

#### 15.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI\_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI\_DATA).

#### 15.4.6.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

#### 15.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ( $i = 0$  or  $1$ ) (see also Table 15-36):

- The DSS.RFBI\_CONFIGi[10:9] CYCLEFORMAT bit field is set to 0x3 (three cycles for two pixels).
- The DSS.RFBI\_DATA\_CYCLE1\_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI\_DATA\_CYCLE2\_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI\_DATA\_CYCLE3\_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

**Table 15-36. 16-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle

#### 15.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

#### 15.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

#### 15.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI\_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

#### 15.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI\_A0 signal), WE (RFBI\_WE signal), RE (RFBI\_RE signal), and CSx (RFBI\_CSx signal, with x = 0, 1) is programmable.

Table 15-37 describes the read/write function.

**Table 15-37. Read/Write Function Description**

A0 (RFBI_A0)	WE (RFBI_WE)	RE (RFBI_RE)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI\_Cs cycle time, as defined in [Table 15-38](#), is required to keep the RFBI\_CSx signal asserted between write transfers of multiple pixels.

[Table 15-38](#) indicates the minimum cycle time for RFBI\_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1 pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

**Table 15-38. Minimum Cycle Time for CSx/WE Always Asserted**

RFBI Performance	RFBI_CONFIGi[10:9] CYCLEFORMAT	RFBI_CONFIGi[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

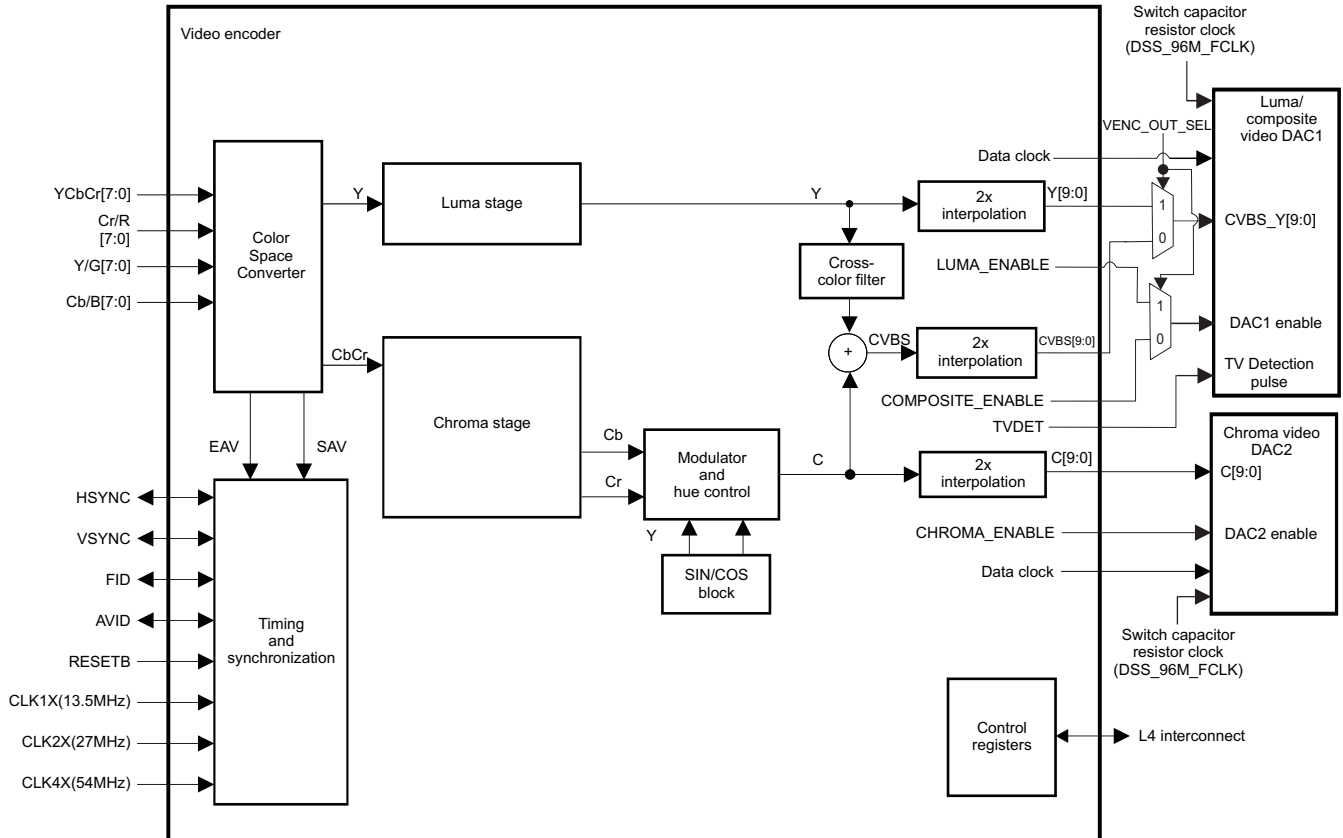

### 15.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC (for more information, see [Section 15.2, Display Subsystem Environment](#)). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

[Figure 15-109](#) shows an overview of the video encoder architecture.

Figure 15-109. Video Encoder Architecture Overview

dss-079

**Note:** Output video mode can be either composite video (CVBS output) or Separate video (s-video: Luma and chroma outputs):

- Composite video: DAC1 is used
  - Separate video (luma/chroma): Both DAC1 (luma) and DAC2 (chroma) are used
- The selection is programmed with DSS.DSS\_CONTROL[6] VENC\_OUT\_SEL bit. Composite video is the default selection.

### 15.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field VENC\_F\_CONTROL[7:6] register to 0x1.

Table 15-39. 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16
Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

### 15.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC\_GAIN\_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC\_BLACK\_LEVEL and DSS.VENC\_BLANK\_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

### 15.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC\_GAIN\_U and DSS.VENC\_GAIN\_V register bits.

### 15.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S\_CARR = \text{ROUND} ([F_{sc}/F_{clkenc}] \times 2^{32})$$

where:

$F_{sc}$  = Frequency of the subcarrier

$F_{clkenc}$  = Frequency of the internal video encoder

The DSS.VENC\_S\_CARR register controls the subcarrier frequency. The DSS.VENC\_C\_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC\_C\_PHASE. Table 15-40 presents the VENC\_S\_CARR register values depending the standard and pixel type used.

**Table 15-40. VENC\_S\_CARR Register Recommended Values**

Standard	Pixel Type	Subcarrier Frequency (F <sub>sc</sub> ) (MHz)	F <sub>clkenc</sub> (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I	ITU-R601	4.43361875	27	0x2A098ACB
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I	Square pixel	4.43361875	29.50	0x26798C0C

#### CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset
- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC\_C\_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC\_BSTAMP\_WSS\_DATA[6:0] BSTAP bit field sets the amplitude of the color burst. The DSS.VENC\_M\_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC\_M\_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC\_M\_CONTROL[5] PALPHS bit selects one of these sequences.

#### 15.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see [Table 15-41](#)).

**Table 15-41. Closed-Caption Data Format**

MSB							LSB
Odd parity	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC\_L21\_WC\_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC\_L21\_WC\_CTL L21EN[1] bit enables closed-caption encoding in even fields.

There is a 4-line offset between the value programmed in the DSS.VENC\_LN\_SEL[4:0] SLINE bit field and the scan line where closed caption is to be encoded. Program the value 0x11 to activate the closed caption on line 21. The DSS.VENC\_LN\_SEL[25:16] LN21\_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC\_LINE21[7:0] L21O and DSS.VENC\_LINE21[15:8] L21O bit fields contain the first and the second bytes of closed-caption data to be encoded in the odd field. The DSS.VENC\_LINE21[23:16] L21E and DSS.VENC\_LINE21[31:24] L21E bit fields contain the first and the second bytes of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC\_STATUS[4] CCE or DSS.VENC\_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC\_STATUS[4] CCE bit or the DSS.VENC\_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in [Figure 15-110](#), a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.VENC\_CC\_CARR\_WSS\_CARR[15:0] FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xflines) for NTSC-601. The closed-caption running clock common frequencies are detailed in [Table 15-42](#).

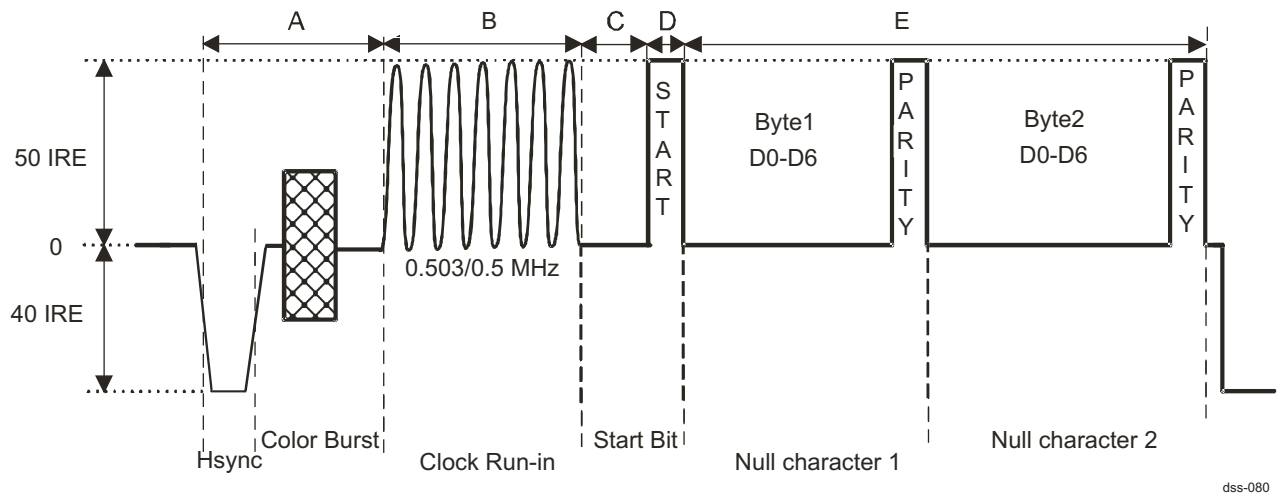

**Table 15-42. Closed-Caption Run Clock Frequency Settings**

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

Figure 15-110 shows the parameters of closed-caption line data implemented in different standards.

**Figure 15-110. Closed Captioning Timing**

**Notes:**

- The interval A is controlled by the DSS.VENC\_LN\_SEL[25:16] LN21\_RUNIN bit field.
- The interval B is controlled by DSS.VENC\_CC\_CARR\_WSS\_CARR[15:0] FCC bit field.

**Table 15-43. Closed-Caption Standard Timing Values**

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 μs	10.500 μs	10.750 μs	10.000 μs	10.500 μs	11.000 μs
B	Clock running		12.910 μs			12.910 μs	
C	Clock running to third start bit		3.972 μs			3.972 μs	
D	Start bit		1.986 μs			1.986 μs	
E	Data characters		31.778 μs			31.778 μs	

**Note:** All timing values listed in Table 15-43 are measured from the mid-point (half amplitude) on all edges.

For a complete description of copy protection including CGMS-A, please refer to CEA-608-x standard

### 15.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC\_L21\_WC\_CTL[14:13] EVEN\_ODD\_EN bit and by programming the VENC\_BSTAMP\_WSS\_DATA[27:8] WSS\_DATA bit field.

The running clock frequency is controlled by the DSS.VENC\_CC\_CARR\_WSS\_CARR[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in [Table 15-44](#)

**Table 15-44. Wide-Screen Signaling Run Clock Frequency Settings**

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.VENC\_L21\_WC\_CTL[12:8] LINE bit field.

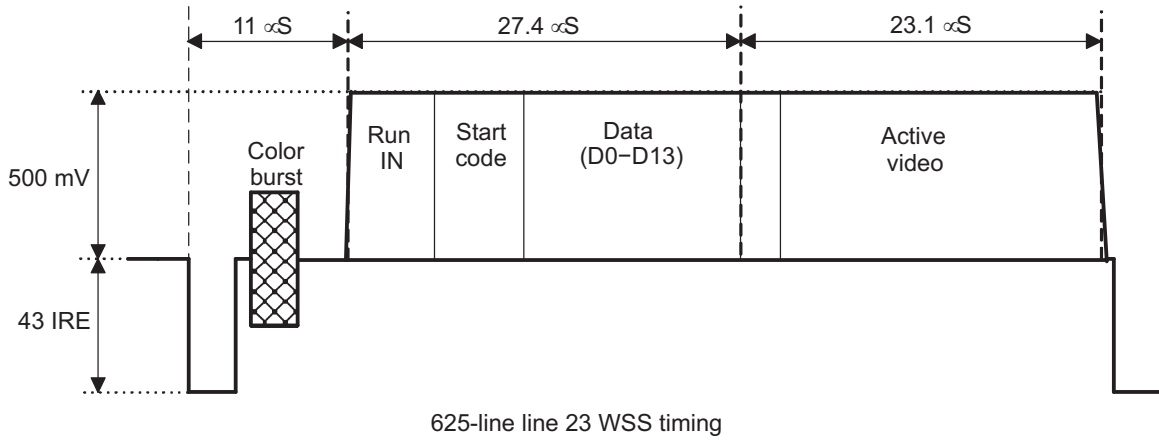

#### CAUTION

The setting of the LINE[4:0] bit field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line  $0x16 + 1 = 0x17$  (23rd line). Note that the default value is  $0x14 + 1 = 0x15$  (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line  $0x10 + 4 = 0x14$  (20th line). Note that the default value is  $0x14 + 4 = 0x18$  (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 15-111](#).

Figure 15-111. WSS Timing

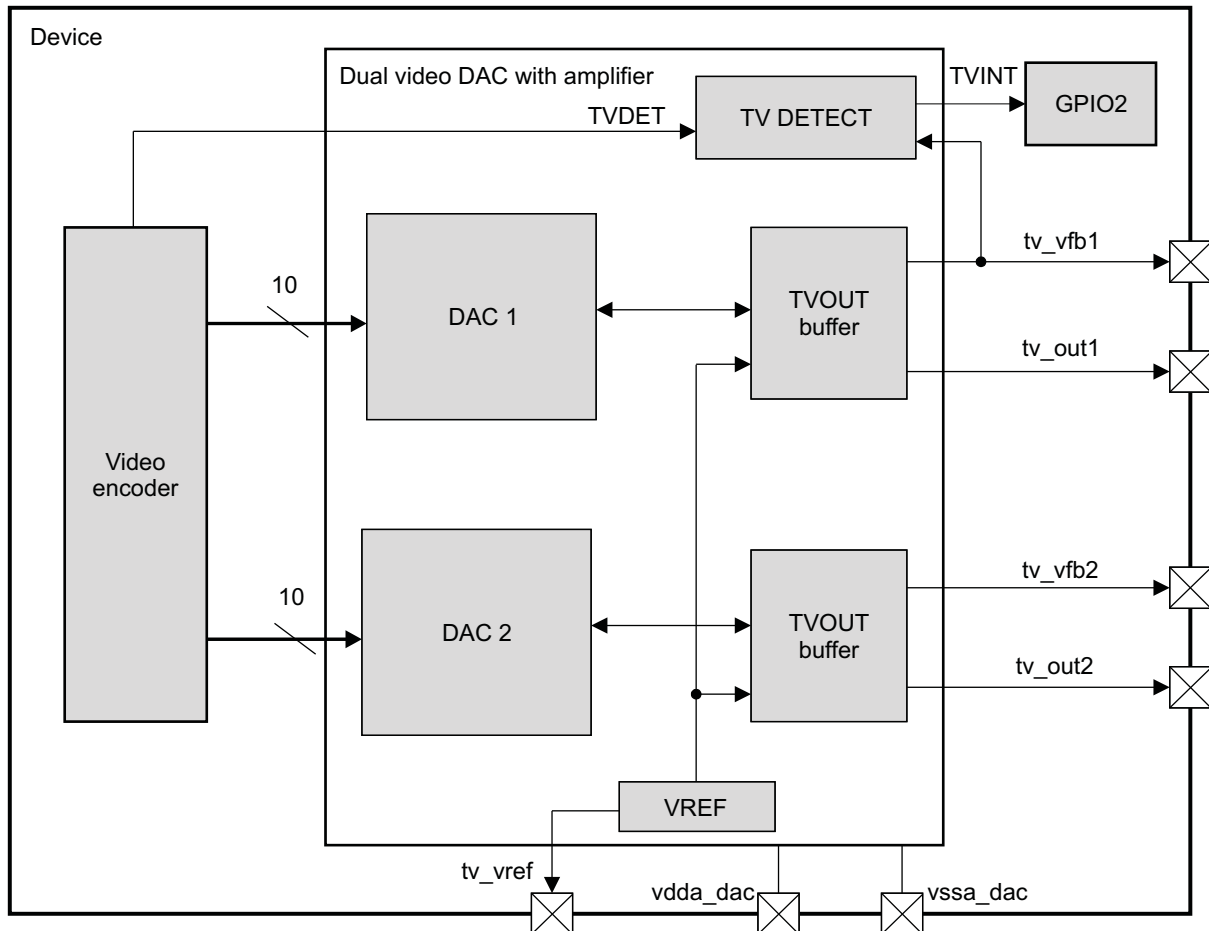

dss-081

### 15.4.7.7 Video DAC Architecture

Figure 15-112 shows the architecture of the dual 10-bit video DAC.

**Figure 15-112. Dual 10-Bit Video DAC Architecture**

dss-082

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering DAC is used to generate the video analog signal. The video mode DAC 1 (luma/composite) also includes the TV detection/disconnection and power-down mode features.

### 15.4.7.8 Video DC/AC Coupled TV Load

The dual 10-bit video DAC supports both dc-coupled and ac-coupled TV loads. The CONTROL.CONTROL\_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: Dc coupling; 1: Ac coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

---

**Note:** When dc coupling is used, note that there is a 385-mV dc offset at the TVOUT output (tv\_out1 for DAC1 and tv\_out2 for DAC2).

---

### 15.4.7.9 TV Detection/Disconnection Pulse Generation and Usage

### 15.4.7.9.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the dual video DAC module.

---

**Notes:**

- The TV detection/disconnection feature is supported only for VDAC1.
  - The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.
- 

This block compares the output (tv\_out1) to reference (tv\_vref) voltages, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is ac or dc coupling to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC\_GEN\_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC\_GEN\_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

### 15.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
  - Program the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
  - Set the DSS.VENC\_GEN\_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
  - Set the DSS.VENC\_GEN\_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
3. Set the VENC\_OUTPUT\_CONTROL[0] LUMA\_ENABLE bit (in s-video mode) or the VENC\_OUTPUT\_CONTROL[1] COMPOSITE\_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the vdda\_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I<sup>2</sup>C interface connected to the power IC (TWL4030 device).
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

**CAUTION**

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

**15.4.7.9.3 TV Disconnection Procedure**

The TV disconnection procedure is the following:

1. Initial setup:
  - Program the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
  - Set the DSS.VENC\_GEN\_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
  - Set the DSS.VENC\_GEN\_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC\_TVDETGP\_INT\_START\_STOP\_X and DSS.VENC\_TVDETGP\_INT\_START\_STOP\_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC\_OUTPUT\_CONTROL[0] LUMA\_ENABLE bit (in s-video mode) or the VENC\_OUTPUT\_CONTROL[1] COMPOSITE\_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the vdda\_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I<sup>2</sup>C interface connected to the power IC (TWL4030 device).

**CAUTION**

- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

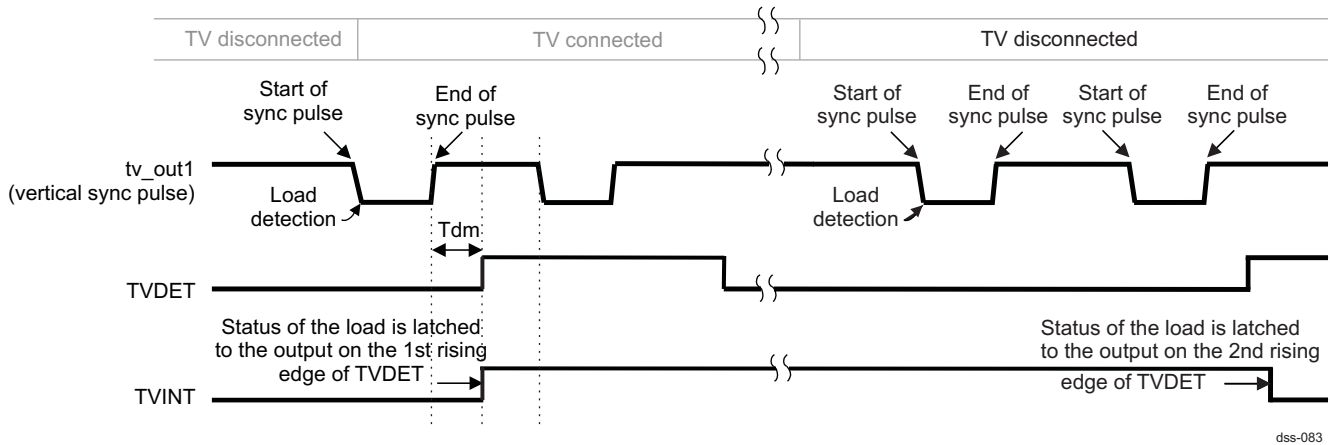

**15.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform**

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 15.4.7.9.2, TV Detection Procedure](#), and in [Section 15.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is T<sub>d</sub>, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

If dc-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 15-113](#) shows the waveforms for the dc-coupling TV detect pulse (TVDET) when load is connected and disconnected.

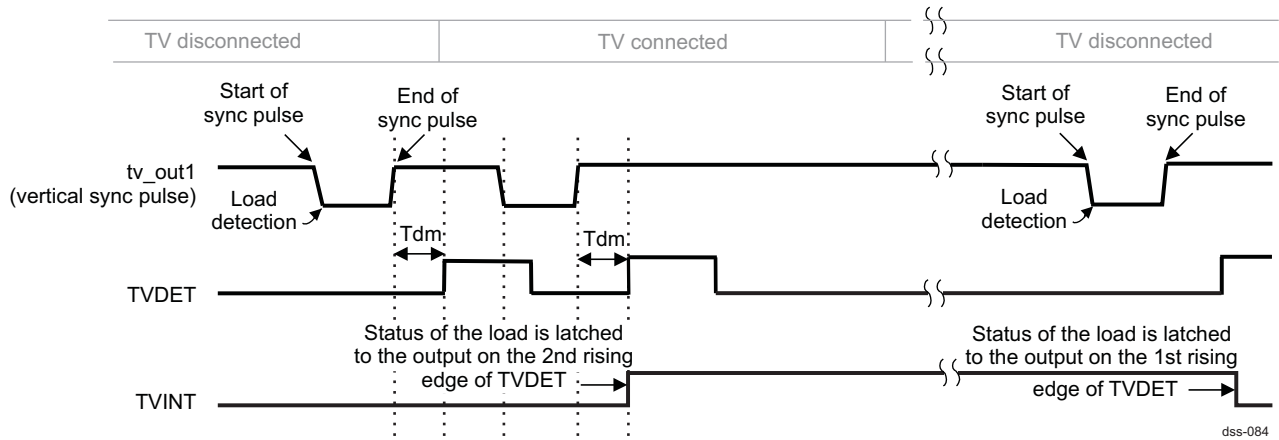

**Figure 15-113. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected**

If ac-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 15-114 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

**Figure 15-114. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected**

**Notes:**

- When setting the DSS.VENC\_TVDEBTGP\_INT\_START\_STOP\_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the tv\_out1 output signal.

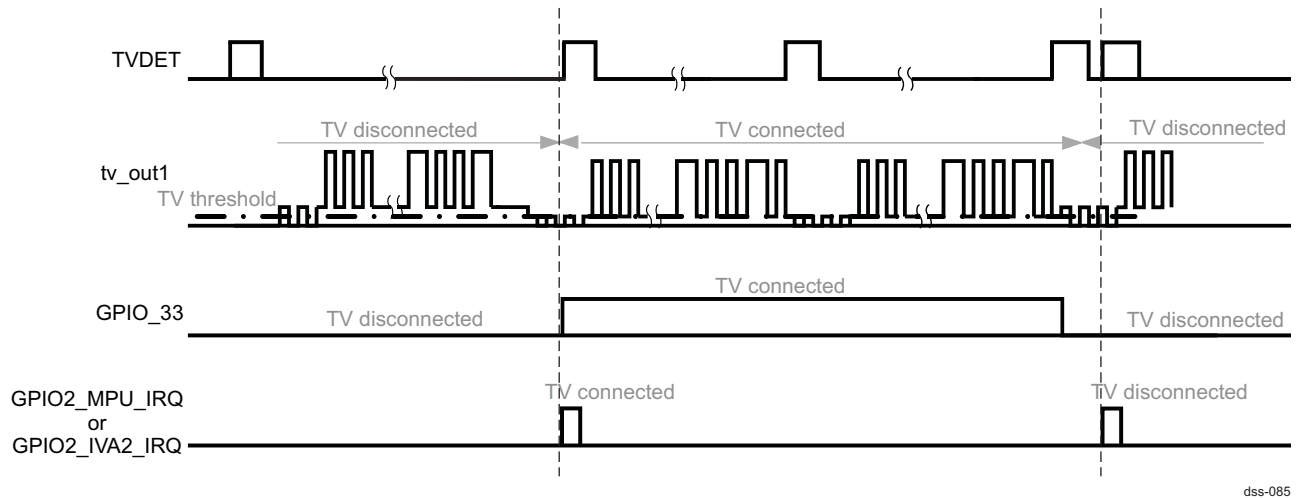

**15.4.7.9.5 TV Detection/Disconnection Usage**

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For dc operation, the tv\_out1 voltage is compared against a voltage reference (tv\_vref) that makes the comparator trigger in each sync pulse while the load is connected. For ac operation, the tv\_out1 voltage is compared against a voltage reference (tv\_vref) that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

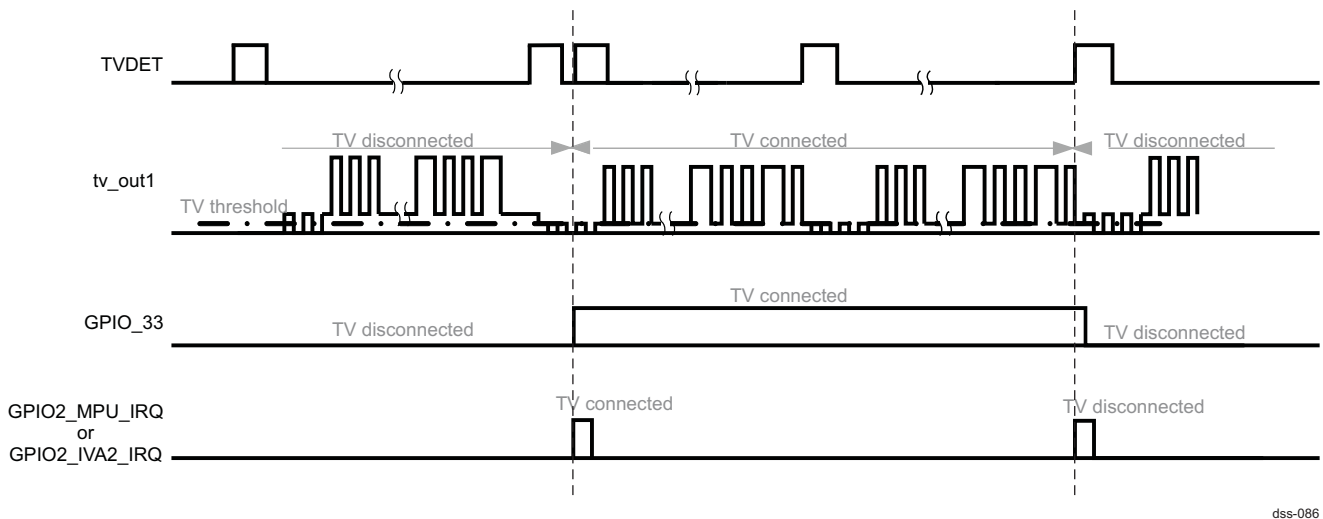

For dc-coupling mode, see Figure 15-115 and for ac-coupling mode, see Figure 15-116

**Note:** Because the video DAC and the video encoder must be awake for connection detection, consider that the video DAC can take up to 10  $\mu$ s to wake up.

**Figure 15-115. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode**

**Figure 15-116. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode**

#### 15.4.7.10 Video DAC Bypass Mode

The dual 10-bit video DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the VFB pins (tv\_vfb1 for DAC1 and tv\_vfb2 for DAC2).

This bypass mode is activated by setting the CONTROL.CONTROL\_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL\_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

**Note:** In bypass mode:

- the tv\_out1 pin requires a RSET resistor connected to the ground. The typical value of the RSET resistor is 3.92 K.
- both tv\_vfb1 and tv\_vfb2 pins require a RLOAD resistor connected to the ground. The typical value of the RLOAD resistor is 976.

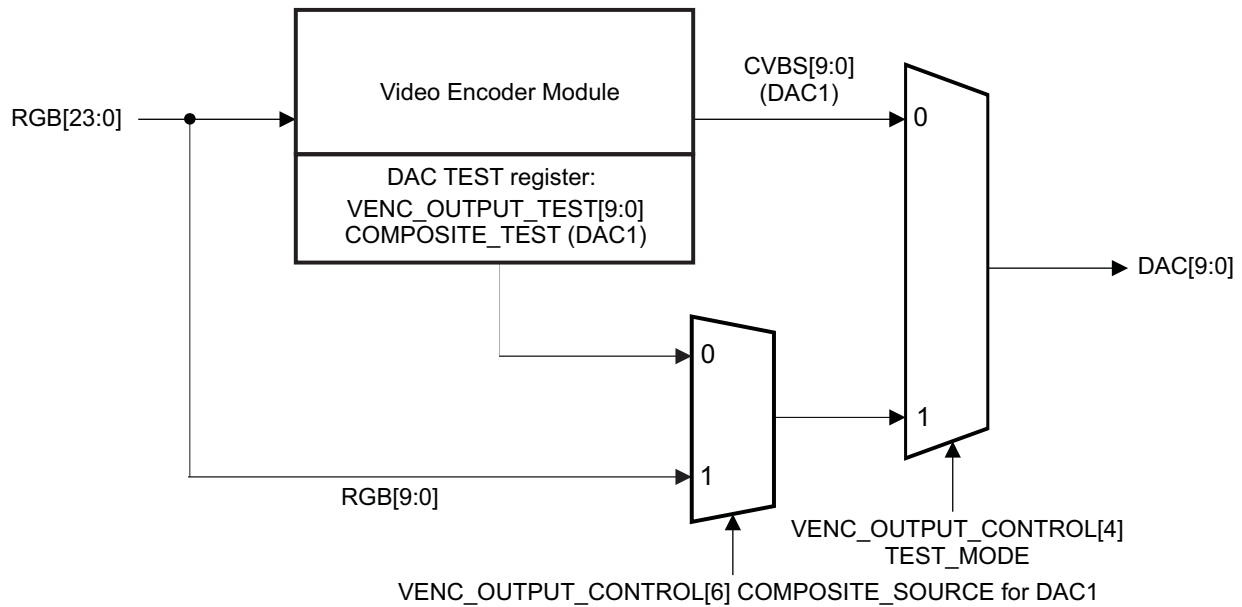

**CAUTION**

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external amplifier is needed on the tv\_vfb1 and tv\_vfb2 pins.

**15.4.7.11 Video Dual-DAC Test Mode**

The DAC can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DAC. See [Figure 15-117](#) for video DAC test in composite video mode, and see [Figure 15-118](#) for video DAC test in separate video mode.

**Figure 15-117. DAC Test Mode in Composite Video Mode**

dss-087

**Figure 15-118. DAC Test Mode in Separate video Mode**

dss-088

- Use the DSS.VENC\_OUTPUT\_CONTROL[4] TEST\_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC\_OUTPUT\_CONTROL[7] CHROMA\_SOURCE bit for DAC2 and either the DSS.VENC\_OUTPUT\_CONTROL[6] COMPOSITE\_SOURCE bit (in composite video mode) or the DSS.VENC\_OUTPUT\_CONTROL[5] LUMA\_SOURCE bit (in s-video mode) for DAC1 to select the test mode:
  - 0x0: From the internal register DSS.VENC\_OUTPUT\_TEST[25:16] CHROMA\_TEST bit field for DAC2 and either DSS.VENC\_OUTPUT\_TEST[9:0] COMPOSITE\_TEST bit field (composite video) or DSS.VENC\_OUTPUT\_CONTROL[25:16] LUMA\_TEST (s-video mode) for DAC1
  - 0x1: From the video port G[1:0], B[7:0]

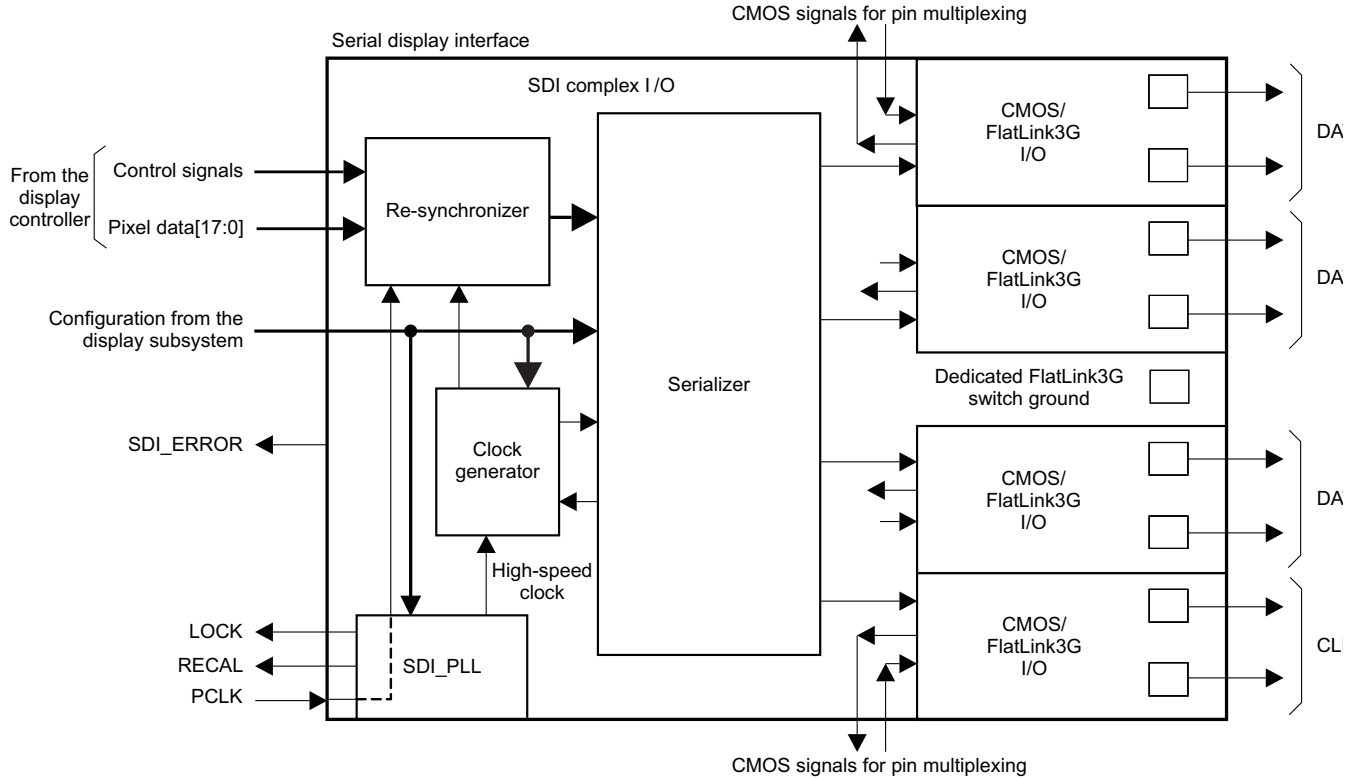

**Note:** In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

### 15.4.8 SDI Functionalities

The SDI interface has three main functions:

- A PLL (SDI\_PLL) to multiply or divide the pixel clock frequency (PCLK) up to the required data rate. The pixel clock frequency range is 4-65 MHz. This clock may be divided by 2 above 32 MHz to meet the PLL input reference timing requirements.
  - A specific IP block to output the data in the chosen serial format
  - Output buffers to transmit the small swing differential signals
- The last two functions are combined in the complex I/O module. [Figure 15-119](#) shows the SDI architecture.

Figure 15-119. SDI Architecture Overview

**Notes:**

- The RECAL status indicates when the SDI\_PLL must be recalibrated (0: No recalibration is required; 1: Recalibration is required).  
This status is connected to the GPIO\_80 internal signal of the GPIO3 module. For additional information, see [Chapter 25, General-Purpose Interface](#).
- The LOCK status indicates when the SDI\_PLL is locked (0: PLL not locked; 1: PLL locked). This status is connected to the GPIO\_81 internal signal of the GPIO3 module. For additional information, see [Chapter 25, General-Purpose Interface](#).  
For more information about lock and recalibration, see [Chapter 4, Power, Reset, and Clock Management](#).
- The SDI\_ERROR status is indicated when the SDI module is in error mode (0: No error; 1: SDI in error). This status allows monitoring error conditions, such as inconsistent configuration or internal loss of synchronization. It is connected to the GPIO\_82 internal signal of the GPIO3 module. For additional information, see [Chapter 25, General-Purpose Interface](#).

## 15.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI, the SDI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)  
Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support  
Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support  
Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.
- TI FlatLink 3G-compliant LCD panel support  
Configure the SDI, configure the video encoder, and then configure the display controller.

### 15.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC\_CONTROL[0] LCDENABLE bit to 0.
  - a. Reset the frame done status bit by writing 1 in the DSS.DISPC\_IRQSTATUS[0] FRAMEDONE bit.
  - b. Wait until the DSS.DISPC\_IRQSTATUS[0] FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
  - PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit set to 1
  - PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit set to 1
 Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS\_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

### 15.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS\_CONTROL[0] DSS\_CLK\_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS\_CONTROL[2] VENC\_CLOCK\_MODE bit and the DSS.DSS\_CONTROL[3] VENC\_CLOCK\_X4 bit for TV set support.
3. To configure the top level of the DAC, set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit for TV set support (if required).
4. Configure the TI FlatLink 3G-compliant LCD panel through the SPI interface to use the serial interface display.
5. Configure the RFBI module and/or the SDI module and/or the video encoder as needed.
6. Configure the display controller.

### 15.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC\_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC\_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC\_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC\_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC\_CONTROL[5] GOLCD or DSS.DISPC\_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 15-45 lists the shadow registers.

**Table 15-45. Shadow Registers**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CONTROL	X <sup>(1)</sup>	X <sup>(1)</sup>
DSS.DISPC_CONFIG	X	X
DSS.DISPC_DEFAULT_COLOR_m (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR_m (m = 1)		X
DSS.DISPC_TRANS_COLOR_m (m = 0)	X	
DSS.DISPC_TRANS_COLOR_m (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X	
DSS.DISPC_SIZE_DIG		X
DSS.DISPC_SIZE_LCD	X	
DSS.DISPC_GFX_BA <sub>j</sub> (j = 0,1)	X	X
DSS.DISPC_GFX_POSITION	X	X
DSS.DISPC_GFX_SIZE	X	X
DSS.DISPC_GFX_ATTRIBUTES	X	X
DSS.DISPC_GFX_FIFO_THRESHOLD	X	X
DSS.DISPC_GFX_ROW_INC	X	X
DSS.DISPC_GFX_PIXEL_INC	X	X
DSS.DISPC_GFX_WINDOW_SKIP	X	X
DSS.DISPC_GFX_TABLE_BA	X	X
DSS.DISPC_GFX_PRELOAD	X	X
DSS.DISPC_CPR_COEF_R	X	
DSS.DISPC_CPR_COEF_G	X	
DSS.DISPC_CPR_COEF_B	X	
DSS.DISPC_VID <sub>n</sub> _BA <sub>j</sub> (j= 0,1)	X	X
DSS.DISPC_VID <sub>n</sub> _POSITION	X	X
DSS.DISPC_VID <sub>n</sub> _SIZE	X	X

<sup>(1)</sup> Some of the register bit fields are shadow bits. For more information, see [Section 15.7, Display Subsystem Register Manual](#).

**Table 15-45. Shadow Registers (continued)**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_VIDn_ATTRIBUTES	X	X
DSS.DISPC_VIDn_FIFO_THRESHOLD	X	X
DSS.DISPC_VIDn_ROW_INC	X	X
DSS.DISPC_VIDn_PIXEL_INC	X	X
DSS.DISPC_VIDn_FIR	X	X
DSS.DISPC_VIDn_PICTURE_SIZE	X	X
DSS.DISPC_VIDn_ACCUI (l = 0,1)	X	X
DSS.DISPC_VIDn_FIR_COEF_Hi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_HVi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_Vi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_CONV_COEFi (i = 0 to 4)	X	X
DSS.DISPC_VIDn_PRELOAD	X	X
DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

### 15.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC\_SYSCONFIG
- DSS.DISPC\_SYSSTATUS
- DSS.DISPC\_IRQSTATUS
- DSS.DISPC\_IRQENABLE

### 15.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

#### 15.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC\_CONTROL
- DSS.DISPC\_GFX\_BAj
- DSS.DISPC\_GFX\_ATTRIBUTES
- DSS.DISPC\_GFX\_ROW\_INC
- DSS.DISPC\_GFX\_PIXEL\_INC
- DSS.DISPC\_GFX\_FIFO\_THRESHOLD
- DSS.DISPC\_GFX\_TABLE\_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC\_GFX\_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC\_GFX\_ATTRIBUTES[7:6] GFXBURSTSIZ field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC\_GFX\_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default

preload configuration uses the DSS.DISPC\_GFX\_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC\_GFX\_ATTRIBUTES[11] GFXFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC\_GFX\_BA<sub>j</sub> registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC\_GFX\_BA0 defines the base address of the even field; and DSS.DISPC\_GFX\_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC\_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD register): The low threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC\_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD bit field) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC\_CONFIG[14] FIFOMERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC\_CONFIG[3] PALETTEGAMMATABLE bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC\_GFX\_TABLE\_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

---

**Note:** In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

---

- Graphics Priority (DSS.DISPC\_GFX\_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC\_GFX\_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

### 15.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- [DSS.DISPC\\_CONFIG](#)
- [DSS.DISPC\\_GFX\\_POSITION](#)
- [DSS.DISPC\\_GFX\\_SIZE](#)
- [DSS.DISPC\\_GFX\\_ATTRIBUTES](#)

The graphics layer is enabled/disabled by setting/resetting the [DSS.DISPC\\_GFX\\_ATTRIBUTES\[0\]](#) GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the [DSS.DISPC\\_CONTROL\[6\]](#) GODIGITAL or [DSS.DISPC\\_CONTROL\[5\]](#) GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

### 15.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format ([DSS.DISPC\\_GFX\\_ATTRIBUTES\[4:1\]](#) GFXFORMAT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position ([DSS.DISPC\\_GFX\\_POSITION\[10:0\]](#) GFXPOSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position ([DSS.DISPC\\_GFX\\_POSITION\[26:16\]](#) GFXPOSY bit field): The default value of this bit field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width ([DSS.DISPC\\_GFX\\_SIZE\[10:0\]](#) GFXSIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the [DSS.DISPC\\_GFX\\_ATTRIBUTES\[7:6\]](#) GFXBURSTSIZE bit field (in bytes).

---

**Note:** When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the [DSS.DISPC\\_GFX\\_ROW\\_INC](#) register is not 1. When [DSS.DISPC\\_GFX\\_ROW\\_INC](#) register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

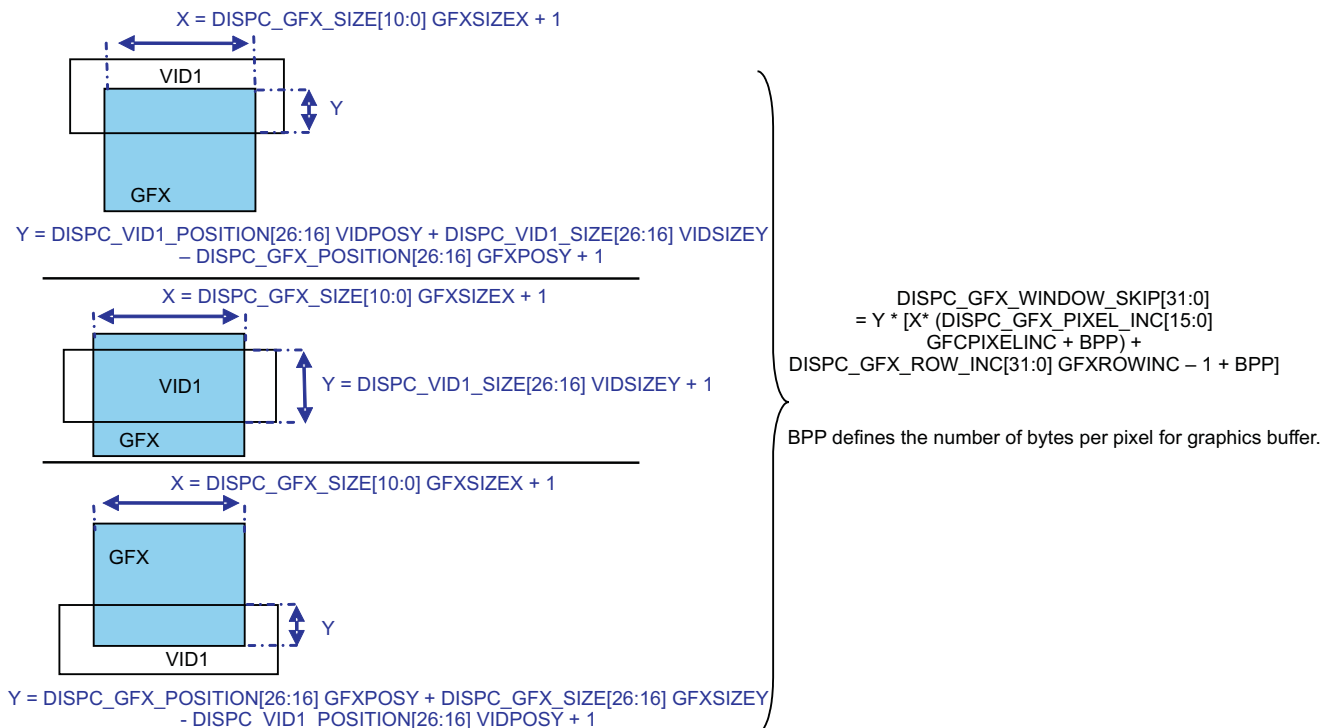

---

- Graphics window height ([DSS.DISPC\\_GFX\\_SIZE\[26:16\]](#) GFXSIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the graphics layer and the position, the height

- should be adjusted by software to limit the bottom edge of the window inside the screen
- Graphics data endianness (DSS.DISPC\_GFX\_ATTRIBUTES[10] GFXENDIANNESS bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
  - Graphics data nibble mode (DSS.DISPC\_GFX\_ATTRIBUTES[9] GFXNIBBLEMODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
  - Graphics replication logic enable (DSS.DISPC\_GFX\_ATTRIBUTES[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
  - Graphics window skip enable (DSS.DISPC\_CONTROL[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field should be reset. When the color key is used, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field should be reset.
  - Graphics window skip (DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFXWINDOWSKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

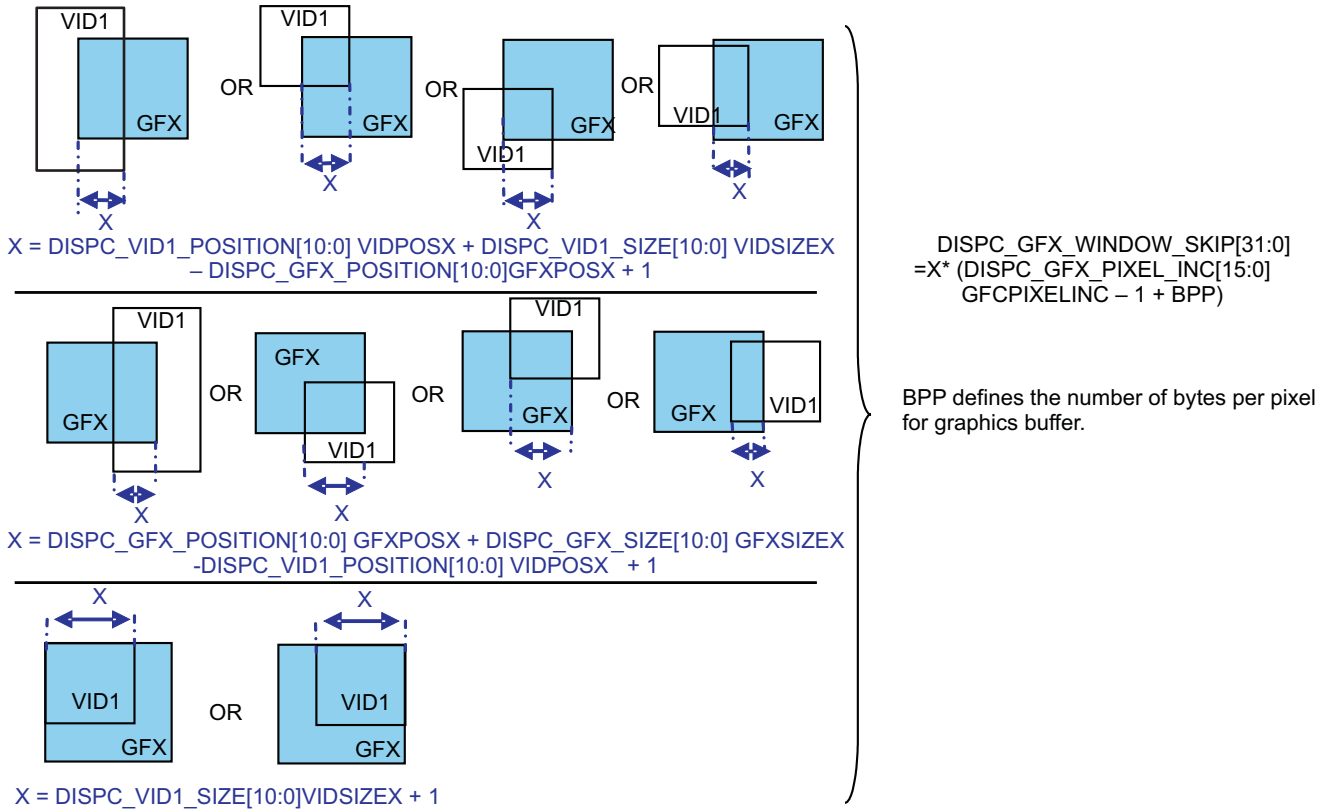

Figure 15-120 through Figure 15-122 give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

Figure 15-120. Overlay Optimization: Case 1

### 15.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

#### 15.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC\_CONTROL
- DSS.DISPC\_VIDn\_BA0

- [DSS.DISPC\\_VIDn\\_ATTRIBUTES](#)
- [DSS.DISPC\\_VIDn\\_ROW\\_INC](#)
- [DSS.DISPC\\_VIDn\\_PIXEL\\_INC](#)
- [DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#)
- [DSS.DISPC\\_VIDn\\_PICTURE\\_SIZE](#)

The following fields define the attributes of the graphics DMA engine:

- Video layer enable ([DSS.DISPC\\_VIDn\\_ATTRIBUTES](#)[0] VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size ([DSS.DISPC\\_VIDn\\_ATTRIBUTES](#)[15:14] VIDBURSTSIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration ([DSS.DISPC\\_VIDn\\_ATTRIBUTES](#)[19] VIDFIFOPRELOAD bit): The default preload configuration uses the [DSS.DISPC\\_VIDn\\_PRELOAD](#) register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the [DSS.DISPC\\_VIDn\\_ATTRIBUTES](#)[19] VIDFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
  - Active matrix (TFT) display: [DSS.DISPC\\_VIDn\\_PRELOAD](#)[11:0] PRELOAD = 0xB0 (value is 176)
  - Color passive matrix (STN) display: [DSS.DISPC\\_VIDn\\_PRELOAD](#)[11:0] PRELOAD = 0x110 (value is 272)
  - Monochrome passive matrix (STN) display: [DSS.DISPC\\_VIDn\\_PRELOAD](#)[11:0] PRELOAD = 0x1B0 (value is 432)
- Base address of the video buffer in system memory ([DSS.DISPC\\_VIDn\\_BA](#)<sub>j</sub> registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register [DSS.DISPC\\_VIDn\\_BA0](#) defines the base address of the even field, and [DSS.DISPC\\_VIDn\\_BA1](#) defines the base of the odd field in the case of an external synchronization and based on the value of the input signal [DISPC\\_FID](#) and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold ([DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#) register): The low threshold ([DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#)[11:0] VIDFIFOWHRESHOLD) and the high threshold ([DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#)[27:16] VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the [DSS.DISPC\\_CONFIG](#)[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the [DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#)[11:0] VIDFIFOWHRESHOLD bit field with n corresponding to the active video channel 1 or 2) and the high threshold ([DSS.DISPC\\_VIDn\\_FIFO\\_THRESHOLD](#)[27:16] VIDFIFOHIGHTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the [DSS.DISPC\\_CONFIG](#)[14] FIFOMERGE bit reset value is 0).
- Video buffer width ([DSS.DISPC\\_PICTURE\\_SIZE](#)[10:0] VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.

- Video buffer height (DSS.DISPC\_PICTURE\_SIZE[26:16] VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC\_VIDn\_ATTRIBUTES[17] VIDENDIANNESS bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

### 15.5.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC\_CONFIG
- DSS.DISPC\_VIDn\_POSITION
- DSS.DISPC\_VIDn\_SIZE
- DSS.DISPC\_VIDn\_ATTRIBUTES
- DSS.DISPC\_VIDn\_FIR
- DSS.DISPC\_VIDn\_PICTURE\_SIZE
- DSS.DISPC\_VIDn\_FIR\_COEF\_Hi (with i = 0 to 7)
- DSS.DISPC\_VIDn\_FIR\_COEF\_HVi (with i = 0 to 7)
- DSS.DISPC\_VIDn\_CONV\_COEFi (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRIBUTES[0] VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC\_CONTROL[6] GODIGITAL or DSS.DISPC\_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

### 15.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC\_VIDn\_ATTRIBUTES[4:1] VIDFORMAT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC\_VIDn\_POSITION[10:0] VIDPOSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC\_VIDn\_POSITION[26:16] VIDPOSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC\_VIDn\_SIZE[10:0] VIDSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC\_VIDn\_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).

---

**Note:** When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC\_VIDn\_ROW\_INC register is not 1. When the DSS.DISPC\_VIDn\_ROW\_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

---

- Video window height (DSS.DISPC\_VIDn\_SIZE[26:16] VIDSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen.

Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.

- Video picture width in system memory (DSS.DISPC\_VIDn\_PICTURE\_SIZE[10:0] VIDORGSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC\_VIDn\_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC\_VIDn\_PICTURE\_SIZE[26:16] VIDORGSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC\_VIDn\_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC\_VIDn\_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

#### 15.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up-/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRIBUTES[5] VIDRESIZEENABLE bit.

The video vertical up-/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRIBUTES[6] VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up-/downsampling block.

---

**Note:** Vertical and horizontal downsampling are limited to a 1/4 resize factor.

---

After a register change, either the DSS.DISPC\_CONTROL[6] GODIGITAL or DSS.DISPC\_CONTROL[5] GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC\_VIDn\_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[12:0] = 1024 \times \left( \frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \right)$$

dss-E093

(15-4)

**Notes:**

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 0x1, VIDSIZEX[10:0] is replaced by 0x2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.

- Horizontal up-/downsampling increment value (DSS.DISPC\_VIDn\_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[12:0] = 1024 \times \left( \frac{VIDORGSIZEX[10:0]}{VIDSIZEX[10:0]} \right) \tag{15-5}$$

dss-E094

**Notes:**

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.

- Vertical up-/downsampling accumulator value (DSS.DISPC\_VIDn\_ACCUI[25:16] VIDVERTICALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 15-46).
- Vertical up-/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
- Vertical up-/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRIBUTES[21] VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the DSS.DISPC\_VIDn\_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit must be set to 1.
- Vertical up-/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRIBUTES[20] VIDDMAOPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit field is reset, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. If the bit field is set, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization.
- Horizontal up-/downsampling accumulator value (DSS.DISPC\_VIDn\_ACCUI[9:0] VIDHORIZONTALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 15-46).

**Table 15-46. Vertical/Horizontal Accumulator Phase**

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up-/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_HVi registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up-/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC\_VIDn\_FIR\_COEF\_HVi and DSS.DISPC\_VIDn\_FIR\_COEF\_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC\_VIDn\_FIR\_COEF\_HVi is used.

- Horizontal up-/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_Hi and DISPC\_VIDn\_FIR\_COEF\_HVi registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC\_VIDn\_FIR\_COEF\_Hi register and the DSS.DISPC\_VIDn\_FIR\_COEF\_HVi register define the 5-tap horizontal up-/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up-/downsampling block.

Each DSS.DISPC\_VIDn\_FIR\_COEF\_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC\_VIDn\_FIR\_COEF\_HVi register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up-/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see Section 15.6.1.

### 15.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC\_VIDn\_CONV\_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

#### YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \tag{15-6}$$

dssE095

#### YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \tag{15-7}$$

dss-E096

Table 15-47 lists the color space conversion register values.

**Table 15-47. Color Space Conversion Register Values**

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]
RY	298	256	298	256
RCr	409	351	459	394
RCb	0	0	0	0

**Table 15-47. Color Space Conversion Register Values (continued)**

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]
GY	298	256	298	256
GCr	-208	-179	-137	-118

VidFullRange	0	1	0	1

#### 15.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

##### 15.5.3.4.1 Image Data Formats

To understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2-, 4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to [Section 15.4.2.2, Graphics Pipeline](#).

For more information on the video data formats, please refer to [Section 15.4.2.3, Video Pipeline](#).

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to [Section 15.4.2.3.2, Color Space Conversion](#).

##### 15.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. [Figure 15-123](#) illustrates the principle steps for a 90-degree rotation.

Figure 15-123. 90° DMA Rotation Example

Table 15-48. 90-degree DMA Rotation Example Description

Parameter	Description	Additional parameters for formulas
ba	Buffer Base Address in Memory	
IW	Image Width in pixels	$iw = IW - 1$
IH	Image Height in pixels	$ih = IH - 1$
ps	Pixel Size (in bytes)	

Figure 15-123 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). To proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

#### 15.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
  - DSS.DISPC\_GFX\_BAj
  - DSS.DISPC\_GFX\_PIXEL\_INC
  - DSS.DISPC\_GFX\_ROW\_INC
  - DSS.DISPC\_GFX\_ATTRIBUTES
  - DSS.DISPC\_GFX\_POSITION
  - DSS.DISPC\_GFX\_SIZE
  - DSS.DISPC\_GFX\_FIFO\_THRESHOLD
- Video pipelines (VID) 1 and 2:
  - DSS.DISPC\_VIDn\_BAj
  - DSS.DISPC\_VIDn\_PIXEL\_INC
  - DSS.DISPC\_VIDn\_ROW\_INC

- DSS.DISPC\_VIDn\_ATTRIBUTES
- DSS.DISPC\_VIDn\_POSITION
- DSS.DISPC\_VIDn\_SIZE
- DSS.DISPC\_VIDn\_CONV\_COEF0 to DSS.DISPC\_VIDn\_CONV\_COEF4
- DSS.DISPC\_VIDn\_FIFO\_THRESHOLD
- DSS.DISPC\_xxx\_BA<sub>j</sub>: These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see [Table 15-49](#) for the formulas). When using the LCD interface, the registers DISPC\_xxx\_BA0 are used. The registers DISPC\_xxx\_BA1 are only used for the TV output.
- DSS.DISPC\_xxx\_PIXEL\_INC[15:0]: This bit field contains the DMA addressing increment after each pixel. This bit field is used to perform the DSS DMA rotation (see [Table 15-49](#) for the formula).

---

**Note:** When the RGB24 packet format is selected, the only valid value is 1.

---

- DSS.DISPC\_xxx\_ROW\_INC[31:0]: This bit field contains the DMA addressing increment after each row (line) of pixels. This bit field is used to perform the DSS DMA rotation (see [Table 15-49](#) for the formula).

---

**Note:** When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

---

- DSS.DISPC\_xxx\_ATTRIBUTES: These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
  - The following bit fields are used by the graphics pipeline to set up the image format:
    - GFXENABLE: Set this field to activate the hardware path in use.
    - GFXFORMAT: Use this field to specify the format of the graphic frame.
    - GFXROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
    - GFXREPLICATIONENABLE: Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the MSB to fill the LSBs of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
    - GFXCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
  - The following bit fields for the two video pipelines:
    - VIDENABLE: Set this field to activate the hardware path in use.
    - VIDFORMAT: Use this field to specify the format of the video frame (RGB16 or YUV422).
    - VIDCOLORCONVENABLE: If the video is in YUV422 format, set this field to enabled.
    - VIDROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See [Section 15.5.3.4.4](#) for more information.
    - VIDROWREPEATENABLE: Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See [Section 15.5.3.4.4](#) for more information.
    - VIDCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
- DSS.DISPC\_xxx\_POSITION: Use this register to configure the position of the window.
- DSS.DISPC\_xxx\_SIZE: Use this register to configure the size of the window.
- DSS.DISPC\_VIDn\_CONV\_COEF0, DSS.DISPC\_VIDn\_CONV\_COEF1, DSS.DISPC\_VIDn\_CONV\_COEF2, DSS.DISPC\_VIDn\_CONV\_COEF3, and DSS.DISPC\_VIDn\_CONV\_COEF4: These registers contain the conversion coefficients required for YUV-to-RGB color conversion.

- DSS.DISPC\_xxx\_FIFO\_THRESHOLD: Set the low threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

#### 15.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring, use the following settings:

**Figure 15-124. Rotation/Mirroring Settings**

dss-098

**Note:** These registers are shadow registers. To take into account the new values, software users must set the DSS.DISPC\_CONTROL[5] GOLCD bit to 1.

Table 15-49 details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. Table 15-50 lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

**Table 15-49. DMA Rotation Register Settings**

Rotation	Registers	GFX/VIDx <sup>(1)</sup>
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba 1 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x (ih-1) x ps) -(iw x ps) - 1 (iw x (ih-1)) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih-1) x ps -2 x ps -2 x ps
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw - 1) x ps (iw - 1) x ps + 1 -(iw x (ih-1)) x ps - ps + 1

(1)

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See [Table 15-48](#) for more information of these parameters.

---

**Note:** In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

---

**Table 15-50. Video Rotation Register Settings (With RGB24 Packet Format)**

Rotation	Registers (with n = 1 or 2)	SDRAM Direct Access <sup>(1)</sup>
0 degree	DSS.DISPC_VIDn_BAj DSS.DISPC_VIDn_PIXEL_INC DSS.DISPC_VIDn_ROW_INC	ba 1 1
180 degrees	DSS.DISPC_VIDn_BAj DSS.DISPC_VIDn_PIXEL_INC DSS.DISPC_VIDn_ROW_INC	ba+(iw*ih*3)-4 -7 -7

(1)

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
- iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
- h = number of lines - 1 (original picture in system memory)
- ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV422: 4 bytes)

See [Table 15-48](#) for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see [Figure 15-125](#)). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC\_xxx\_BAj, DISPC\_xxx\_PIXEL\_INC, and DISPC\_xxx\_ROW\_INC. [Table 15-51](#) provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 15-125. 90° Rotation With Mirroring

Table 15-51. Register Settings for DMA Rotation With Mirroring

Rotation	Registers	GFX/VIDx <sup>(1)</sup>
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw-1) x ps -2 x ps + 1 2 x (iw-1) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba (iw-1) x ps (-iw x (ih-1)) x ps
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + iw x (ih-1) x ps 1 -2 x iw x ps
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih - 1) x ps (iw - 1) x ps + 1 - (iw x (ih-1)) x ps - ps + 1

(1)

- ba = start address of image buffer in memory
  - iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
  - ih = image height - 1 (number of rows)
  - ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)
- See [Table 15-48](#) for more information of these parameters.

### 15.5.3.4.3 Image Data from External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. To use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see [Section 15.5.3.4.2, Image Data from On-Chip SRAM](#)). The differences are in the setup of the following registers:

- DISPC\_xxx\_ROW\_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, to reach the 2048-pixel line size of the VRFB (see [Table 15-52](#) for the formula).
- DISPC\_xxx\_PIXEL\_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see [Table 15-52](#)).

**Table 15-52. VRFB Rotation - DMA Settings**

Rotation	Registers	GFX/VIDx <sup>(1)</sup>
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 1 (2048 - iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + offset 1 (2048 - ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + offset 1 (2048 - iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + offset 1 (2048 - ih) x ps + 1

(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 15-126 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 15-126 illustrates why this occurs and how the offset is calculated.

Figure 15-126. Offset for VRFB Rotation

dss-099

$\Delta iw$  = Image width delta between the actual image width and the programmed image width because of the page width

$\Delta ih$  = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree:  $\Delta ih$  pixels =  $\Delta ih \times ps$  bytes
- Offset 180-degree:  $2048 \times \Delta ih + \Delta iw$  pixels =  $2048 \times \Delta ih \times ps + \Delta iw \times ps$  bytes
- Offset 270-degree:  $2048 \times \Delta iw$  pixels =  $2048 \times \Delta iw \times ps$  bytes

In the example given above, the delta in the image height is  $256 - 240 = 16$  lines ( $\Delta ih = 16$ ), whereas the exact value of the width can be programmed ( $\Delta iw = 0$ ). In that case, the resulting offset values are:

- YUV:
  - Offset 90-degree:  $16 \times 4$  bytes
  - Offset 180-degree:  $2048 \times 16 \times 4$  bytes
  - Offset 270-degree: 0 bytes
- RGB:
  - Offset 90-degree:  $16 \times 2$  bytes
  - Offset 180-degree:  $2048 \times 16 \times 2$  bytes
  - Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. [Table 15-53](#) provides the DMA settings for VRFB rotation with mirroring.

**Table 15-53. VRFB Rotation With Mirroring - DMA Settings**

Rotation	Registers	GFX/VIDx <sup>(1)</sup>
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + 2048 x (ih - 1) x ps + offset 1 -(2048 + iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 + 2048 x (ih - 1) x ps 1 -(2048 + iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1

(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in [Figure 15-127](#), this applies to 0-degree rotation with mirroring (using VBA 180°), 90° rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): 2048 x  $\Delta ih$  +  $\Delta iw$  pixels = 2048 x  $\Delta ih$  x ps +  $\Delta iw$  x ps bytes
- Offset 90-degree (mirroring): 2048 x  $\Delta iw$  pixels = 2048 x  $\Delta iw$  x ps bytes
- Offset 270-degree (mirroring):  $\Delta ih$  pixels =  $\Delta ih$  x ps bytes

Figure 15-127. Offset for VRFB Rotation With Mirroring

dss-101

15.5.3.4.4 Additional configuration when using YUV format

The rotation flag (DSS.DISPC\_VIDn\_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC\_VIDn\_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 15-54 and Table 15-55 describe the configuration of these registers.

Table 15-54. Video Rotation Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

**Table 15-54. Video Rotation Register Settings (YUV Only) (continued)**

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

**Table 15-55. Video Rotation With Mirroring Register Settings (YUV only)**

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

**Note:** For YUV 4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV 4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

### 15.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC\_CONTROL
- DSS.DISPC\_CONFIG
- DSS.DISPC\_DEFAULT\_COLOR\_m (m=0)
- DSS.DISPC\_TRANS\_COLOR\_m (m=0)
- DSS.DISPC\_TIMING\_H
- DSS.DISPC\_TIMING\_V
- DSS.DISPC\_POL\_FREQ
- DSS.DISPC\_DIVISOR
- DSS.DISPC\_SIZE\_LCD
- DSS.DISPC\_DATA\_CYCLEK
- DSS.DISPC\_CPR\_COEF\_R, DSS.DISPC\_CPR\_COEF\_G, DSS.DISPC\_CPR\_COEF\_B

Setting/resetting the DSS.DISPC\_CONTROL[0] LCDENABLE bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

#### 15.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC\_CONTROL[2]MONOCOLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC\_CONTROL[3] STNTFT bit)

- Color depth (the DSS.DISPC\_CONTROL[9:8] TFTDATALINES bit field)
- Number of lines per panel (the DSS.DISPC\_SIZE\_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE\_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC\_CONTROL[4] M8B bit)

**15.5.3.5.2 LCD Timings**

The following bit fields define the timing generation of HSYNC/VSYNC:

- Horizontal front porch (the DSS.DISPC\_TIMING\_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC\_TIMING\_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC\_TIMING\_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC\_TIMING\_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC\_TIMING\_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC\_TIMING\_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSYNC pixel clock (the DSS.DISPC\_POL\_FREQ[17] ONOFF bit)
- Program HSYNC/VSYNC rise or fall (the DSS.DISPC\_POL\_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC\_POL\_FREQ[13] IHS bit)
- Invert VSYNC (the DSS.DISPC\_POL\_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC\_CONFIG[6] HSYNCGATED bit)
- VSYNC gated (the DSS.DISPC\_CONFIG[7] VSYNCGATED bit)

Table 15-56 describes the programming rules for LCD timing.

**Table 15-56. Programming Rules**

	No Downsampling	Downsampling H or V	Downsampling H + V
$(HBP + HSW + HFP) * PCD$	> 8	> 10	> 20

Figure 15-128 shows the timing values description in the case of an active matrix display.

**Figure 15-128. Timing Values Description (Active Matrix Display)**

dss-102

The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC\_POL\_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC\_POL\_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC\_POL\_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC\_CONFIG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC\_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC\_POL\_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC\_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC\_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC\_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock}/\text{LCD}[7:0])/\text{PCD}[7:0]$$

Table 15-57 through Table 15-60 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

**Table 15-57. Pixel Clock Frequency Limitations - RGB16 and YUV422 Active Matrix Display**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	2 (1) <sup>(1)</sup>	2 (1) <sup>(1)</sup>	2	3	4
	Up	2 (1) <sup>(1)</sup>	2 (1) <sup>(1)</sup>	2	3	4
1:1 - 1:2	3-tap	2	2	4	6	8
	5-tap	PCDmin	PCDmin	PCDmin	PCDmin	PCDmin
1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin	PCDmin

<sup>(1)</sup> The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

**Table 15-58. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono4**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	4	4	8	12	16
	Up	4	4	8	12	16
1:1 - 1:2	3-tap	8	8	16	24	32
	5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

**Table 15-59. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono8**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	8	8	16	24	32
	Up	8	8	16	24	32
1:1 - 1:2	3-tap	16	16	32	48	64
	5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin
1:2 - 1:4		8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin

**Table 15-60. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Color**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	3	3	6	9	12
	Up	3	3	6	9	12
1:1 - 1:2	3-tap	6	6	12	18	24
	5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

**Note:** In case of RGB24 format, [Figure 15-129](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

**Figure 15-129. PCDmin Formulas (V Down-Sampling Only)**

$$h\_ratio = \frac{DISPC\_PPL\_SIZE\_LCD[10:0]PLL}{DISPC\_VIDn\_SIZE[10:0]VIDZSIZE}$$

$$v\_ratio = \frac{DISPC\_VIDn\_PICTURE\_SIZE[10:0]VIDORGSIZE}{DISPC\_VIDn\_SIZE[10:0]VIDSIZE}$$

$$PCDmin = \frac{v\_ratio}{2 \times h\_ratio} \quad 1 < v\_ratio \leq 2$$

$$PCDmin = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad 2 < v\_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by  $n$ ,  $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCDmin\ H\ only, PCDmin\ V\ only)$  as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC\_TIMING\_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC\_TIMING\_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC\_TIMING\_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC\_TIMING\_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC\_TIMING\_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC\_TIMING\_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC\_SIZE[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC\_CONTROL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC\_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC\_CONTROL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC\_CONFIG[0] PIXELGATED bit).

### 15.5.3.5.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC\_TRANS\_COLOR0i register (i = 0))
- Transparency color key enable (the DSS.DISPC\_CONFIG[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC\_CONFIG[11] TCKLCDSELECTION bit)
- The default solid background color is defined in the DSS.DISPC\_DEFAULT\_COLOR\_m[23:0] DEFAULTCOLOR bit field (i=0).
- Alpha blender Enable (DSS.DISPC\_CONFIG[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC\_GLOBAL\_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC\_GLOBAL\_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

---

**Note:** The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

---

---

**Note:** When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

---

When all of these fields are set to the appropriate values, set the DSS.DISPC\_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CONTROL[0] LCDENABLE bit will be set to 1.

### 15.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC\_DATA\_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC\_DATA\_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC\_DATA\_CYCLEk (k=2) register)
- Enable (the DSS.DISPC\_CONTROL[20] TDMENABLE bit)
- Parallel mode (the DSS.DISPC\_CONTROL[22:21] TDMPARALLEMODE field)
- Cycle format (the DSS.DISPC\_CONTROL[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.DISPC\_CONTROL[26:25] TDMUNUSEDBITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CONTROL[0] LCDENABLE bit will be set to 1.

### 15.5.3.5.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC\_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field) with:
  - 0x0 Spatial only (default value)
  - 0x1 Spatial + Temporal over two frames

- 0x2 Spatial + Temporal over four frames
- 0x3 Reserved
- Enable (the DSS.DISPC\_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CONTROL[0] LCDENABLE bit will be set to 1.

#### 15.5.3.5.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC\_CONFIG[15] CPR bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC\_CPR\_COEF\_R, DSS.DISPC\_CPR\_COEF\_G, and DSS.DISPC\_CPR\_COEF\_B, as described in Figure 15-130 through Figure 15-133.

**Figure 15-130. Color Phase Rotation Matrix**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E105

**Figure 15-131. Color Phase Rotation Matrix (R Component Only)**

$$R_{iout} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

**Figure 15-132. Color Phase Rotation Matrix (G Component Only)**

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

**Figure 15-133. Color Phase Rotation Matrix (B Component Only)**

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CONTROL[0] LCDENABLE bit will be set to 1.

### 15.5.3.5.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. [Figure 15-134](#) gives the example of a diagonal matrix and the corresponding equation of the output components.

**Figure 15-134. Diagonal Matrix Configuration**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (RR * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (GG * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (BB * B_{in})$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. [Figure 15-135](#) gives the corresponding matrix and equations for each component.

**Figure 15-135. Example - Diagonal Matrix Configuration**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in}) \Rightarrow R_{out} = R_{in}$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in}) \Rightarrow G_{out} = G_{in}$$

$$\rightarrow B_{out} = \frac{1}{256} * (128 * B_{in}) \Rightarrow B_{out} = 0.5 * B_{in}$$

dss-201

[Figure 15-136](#) shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 15-136. Image With and Without CPR (Diagonal Matrix)

dss-202

A drawback of this diagonal matrix is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

#### 15.5.3.5.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B\_offset) to the Blue component. [Figure 15-137](#) shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

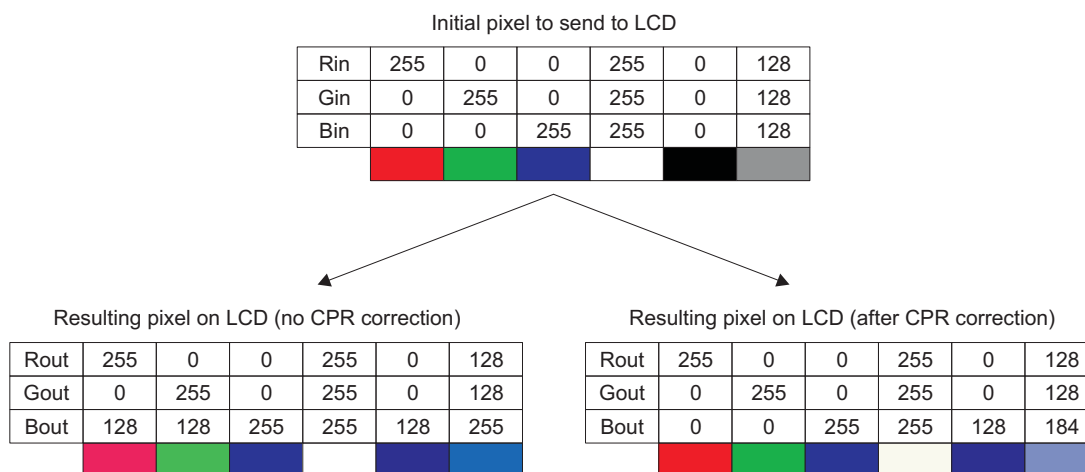

**Figure 15-137. Example - Image With and Without CPR (Standard Matrix)**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (-129 * R_{in} + -129 * G_{in} + 370 * B_{in}) + B_{offset}$$

dss-203

This CPR matrix gives inputs and outputs very close. However, black can not be corrected because of it's zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

### 15.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC\_CONTROL
- DSS.DISPC\_CONFIG
- DSS.DISPC\_DEFAULT\_COLOR\_m (m=1)
- DSS.DISPC\_TRANS\_COLOR\_m (m=1)
- DSS.DISPC\_SIZE\_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC\_CONTROL[1] DIGITALENABLE bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC\_CONTROL[6] GODIGITAL bit and the DSS.DISPC\_CONTROL[1] DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC\_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC\_IRQENABLE[15]

SYNCLOSTDIGITAL bit to 1.

#### 15.5.3.6.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC\_CONTROL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC\_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC\_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

#### 15.5.3.6.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC\_SIZE\_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE\_DIG[10:0] PPL bit field)

#### 15.5.3.6.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC\_TRANS\_COLOR\_m register (m=1))
- Transparency color key enable (the DSS.DISPC\_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC\_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC\_DEFAULT\_COLOR\_m[23:0] DEFAULTCOLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC\_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC\_GLOBAL\_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC\_GLOBAL\_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

---

**Note:** The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

---

---

**Note:** When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

---

When this bit field is set to the appropriate values, set the DSS.DISPC\_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC\_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC\_CONTROL[1] DIGITALENABLE bit will be set to 1.

### 15.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

#### 15.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI\_SYSCONFIG[1] SOFT\_RESET bit to 1. The software can monitor the DSS.DSI\_SYSSTATUS[0] RESET\_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI\_SYSSTATUS[0] RESET\_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

---

**Note:** This software reset is optional as an hardware reset is always performed on the DSI protocol engine at device reset.

---

#### 15.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI\_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI\_SYSCONFIG[0] AUTO\_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

#### 15.5.4.3 Interrupts

There is a single interrupt request: DSI\_IRQ. This interrupt line is merged with another interrupt line from the DISPC\_IRQ in a single interrupt request DSS\_IRQ. The DSI\_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI\_IRQENABLE register: This register indicates the enabled/disabled event for the VCs. Each event for the VC is configured in the DSS.DSI\_VcN\_IRQENABLE register dedicated to the VC number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).
- DSS.DSI\_IRQSTATUS register : The register DSI\_IRQSTATUS flags which VC(s) is/have generated an interrupt. Based on the VC number, the register DSI\_VcN\_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

#### 15.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSI\_PHY\_SCP registers in the DSI complex I/O must be configured. Refer to [Section 15.5.6](#) for more details. [Table 15-61](#) details the register access width limitations for all the DSI modules.

**Table 15-61. Register Access Width Limitations**

Register Name	Register Access Width
All DSI complex I/O register (DSI_PHY_SCP)	32-bit only
All DSI PLL control module registers	32-bit only
<a href="#">DSI_VcN_LONG_PACKET_HEADER</a>	32-bit only
<a href="#">DSI_VcN_SHORT_PACKET_HEADER</a>	32-bit only
<a href="#">DSI_VcN_LONG_PACKET_PAYLOAD</a>	16-bit, 32-bit
All others DSI protocol engine registers	8-bit, 16-bit and 32-bit

### CAUTION

In case of different access width detailed in [Table 15-61](#), an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI\_CTRL register. The interface to the complex I/O is enabled by setting the DSS.DSI\_CTRL[0] IF\_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.DSI\_CTRL[0] IF\_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.DSI\_CTRL[0] IF\_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.DSI\_CTRL[0] IF\_EN bit. When using the video mode, the VC associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.DSI\_CTRL[0] IF\_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.DSI\_VCn\_CTRL[0] VC\_EN
- Set the DSS.DSI\_CTRL[0] IF\_EN bit to 1

#### 15.5.4.5 Virtual Channels

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSS.DSI\_VCn\_CTRL[4] MODE bit):
  - Video mode
  - Command mode
- Data type
- Source (DSS.DSI\_VCn\_CTRL[1] SOURCE bit)
  - Video port
  - L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
  - Short packets (DSS.DSI\_VCn\_CTRL[2] BTA\_SHORT\_EN bit)
  - Long packets (DSS.DSI\_VCn\_CTRL[3] BTA\_LONG\_EN bit)
- DMA request configurations for RX and TX
  - DMA request number (DSS.DSI\_VCn\_CTRL[29:27] DMA\_RX\_REQ\_NB bit field for RX FIFO and DSS.DSI\_VCn\_CTRL[23:21] DMA\_TX\_REQ\_NB bit field for TX FIFO)
  - DMA threshold (DSS.DSI\_VCn\_CTRL[26:24] DMA\_RX\_THRESHOLD bit field for RX FIFO and DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD bit field for TX FIFO)
- Mode speed (DSS.DSI\_VCn\_CTRL[9] MODE\_SPEED bit)
- ECC transmission (DSS.DSI\_VCn\_CTRL[8] ECC\_TX\_EN bit)
- CS transmission (DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN bit)

The VC ID not calculated by the DSI module but provided while writing into the registers [DSI\\_VCn\\_SHORT\\_PACKET\\_HEADER](#) and [DSI\\_VCn\\_LONG\\_PACKET\\_HEADER](#).

#### 15.5.4.6 Packets

The DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)

- DSS.DSI\_CTRL[18] VP\_HSYNC\_END
- DSS.DSI\_CTRL[17] VP\_HSYNC\_START
- DSS.DSI\_CTRL[16] VP\_VSYNC\_END
- DSS.DSI\_CTRL[15] VP\_VSYNC\_START
- DSS.DSI\_CTRL[10] VP\_HSYNC\_POL
- DSS.DSI\_CTRL[11] VP\_VSYNC\_POL
- DSS.DSI\_VCn\_CTRL[1] SOURCE

The DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the VC, it is not possible to transfer concurrently (interleaved in a frame) data using long packets received on the video port and on the L4 interconnect port since the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register is used by the video mode. The register can be unprogrammed by users to send long packets received on the L4 interconnect port only when software users know that there is no expected data on the video port. The software should correctly program the register to send sequentially long packets in video and command modes.

The DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI\_VCn\_CTRL[7] CS\_TX\_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI\_VCn\_LONG\_PACKET\_HEADER and DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD, respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register can be followed by any access.
- A long packet header value with WC>0 written in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register should be followed by one or more writes to the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register.

#### CAUTION

If this sequence is not followed, no error is generated. The access to other DSI registers during this sequence is allowed.

#### 15.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. See [Section 15.5.6, DSI Complex I/O Basic Programming Model](#).

#### 15.5.4.8 Video Mode

The DSS.DSI\_VM\_TIMING1, DSS.DSI\_VM\_TIMING2, DSS.DSI\_VM\_TIMING3, DSS.DSI\_VM\_TIMING4, DSS.DSI\_VM\_TIMING5, DSS.DSI\_VM\_TIMING6, and DSS.DSI\_VM\_TIMING7 registers define the timings of the video mode.

The DSS.DSI\_CTRL[20] BLANKING\_MODE bit defines if the long blanking packets or LPS state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.DSI\_VCn\_CTRL[9] MODE\_SPEED bit is set to 1 (High-Speed mode) to keep the video mode transfer is HS mode during blanking periods (except for the last blanking period since it is required to go LPS at least once per frame).

The DSS.DSI\_CTRL[21] HFP\_BLANKING\_MODE, DSS.DSI\_CTRL[22] HBP\_BLANKING\_MODE and DSS.DSI\_CTRL[23] HSA\_BLANKING\_MODE define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register `DSS.DSI_VCn_LONG_PACKET_HEADER` are correctly handled as header information for video mode long packets, the following registers should be programmed:

- `DSS.DSI_VCn_CTRL[0]` VC\_EN bit set to 1
- `DSS.DSI_VCn_CTRL[4]` MODE bit set to 1
- `DSS.DSI_VCn_LONG_PACKET_HEADER` register access
- `DSS.DSI_VCn_CTRL[0]` VC\_EN bit set to 1

---

**Note:** The `DSS.DSI_VCn_CTRL[1]` SOURCE and `DSS.DSI_VCn_CTRL[9]` MODE\_SPEED bits are ignored by hardware when the video mode is selected (`DSS.DSI_VCn_CTRL[4]` MODE bit set to 1)

---

The interrupt events `SYNC_LOST_IRQ` and `RESYNCHRONIZATION_IRQ` indicates if the DSI protocol engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The `RESYNCHRONIZATION_IRQ` indicates software users that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The `SYNC_LOST_IRQ` and `RESYNCHRONIZATION_IRQ` events can be respectively monitored in `DSS.DSI_IRQSTATUS[18]` `SYNC_LOST_IRQ` and `DSS.DSI_IRQSTATUS[5]` `RESYNCHRONIZATION_IRQ` status bits.

The `DSS.DSI_VM_TIMING2[27:24]` WINDOW\_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

#### 15.5.4.9 Video Port Data Bus

The `DSS.DSI_CTRL[7:6]` VP\_DATA\_BUS\_WIDTH bit field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

#### 15.5.4.10 Command Mode

##### 15.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific VC should be done only when the VC is disabled.

Users should not enable the VC if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated `DSS.DSI_VCn_LONG_PACKET_HEADER` and `DSS.DSI_VCn_LONG_PACKET_PAYLOAD` registers are used to provide data for long packets. The register `DSS.DSI_VCn_SHORT_PACKET_HEADER` is used to provide data for short packets (32-bit long).

For each long packet, the `DSS.DSI_VCn_LONG_PACKET_HEADER` register should be written first and then the `DSS.DSI_VCn_LONG_PACKET_PAYLOAD` register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the `DSS.DSI_VCn_LONG_PACKET_HEADER` register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests only for each VC to the TX FIFO should be kept in order while sending the data to the DSI\_PHY inside the VC requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register is not a multiple of the request threshold value defined in DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD bit field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the DT field. When the bytes are written into the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER, DSS.DSI\_VCn\_LONG\_PACKET\_HEADER, and DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD registers, the hardware should store the information concerning long or short packet. A 1-bit flag should be used for each entry of the TX FIFO.

When the VC is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (threshold value bigger than space left in the TX FIFO for the VC).

---

**Note:** In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

---

When consecutive packets should be sent in HS mode, to ensure that there is no LP transition between them at least one of the following condition should be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chunk FIFO by:

- First disabling the VC resetting DSS.DSI\_VCn\_CTRL[0] VC\_EN bit to 0
- Second change the size of the space of FIFO to 0 by writing the DSS.DSI\_TX\_FIFO\_VC\_SIZE VCn\_FIFO\_SIZE (n is the VC value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI\_PHY, the flush of the FIFO should stop immediately the transfer. Because the FIFO is accessible to users, it must ensure that there are no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

Users can check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant DSS.DSI\_VCn\_CTRL[15] VC\_BUSY bit or by using the interrupt PACKET\_SENT\_IRQ: All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the DSS.DSI\_VCn\_IRQSTATUS[2] PACKET\_SENT\_IRQ status bit.

The DSS.DSI\_CTRL[3] TX\_FIFO\_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled VCs with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC which has the least VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

If users want to use sequential arbitration for all requests for all channels, a single VC should be used. (the VC ID defined in the header provided to the hardware using either the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER or DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register is not used and not modified by the DSI protocol engine).

The register DSS.DSI\_TX\_FIFO\_VC\_SIZE defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO defined by DSS.DSI\_TX\_FIFO\_VC\_SIZE VCn\_FIFO\_SIZE (n corresponds to the VC number n) bit fields should be a multiple of the threshold defined in DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD bit field. Only the

enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by setting the DSS.DSI\_VCn\_CTRL[0] VC\_EN bit to 0. The whole FIFO may not be used by all the VCs at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 15-62 indicates the corresponding values for the size of the space allocated in the FIFO.

**Table 15-62. Virtual Channel TX FIFO Size Values**

DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3]	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of TX FIFO is 128\*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128\*33 bits.

Table 15-63 indicates the start address of the space in the FIFO.

**Table 15-63. Virtual Channel TX FIFO Start Address**

DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]	Start Address
0	0
1	32
2	64
3	96
4	128

**CAUTION**

There must be no overlap of different VCs spaces.

When the TX FIFO is full:

- the overflow interrupt (FIFO\_TX\_OVF\_IRQ) is generated. To monitor this interrupt request, users can read the DSS.DSI\_VCn\_IRQSTATUS[3] FIFO\_TX\_OVF\_IRQ status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software must read the room in the space allocated for the VC in the TX FIFO by reading the DSS.DSI\_TX\_FIFO\_VC\_EMPTINESS register. In case there is no space allocated in the TX FIFO for the VC, the DSS.DSI\_TX\_FIFO\_VC\_EMPTINESS register indicates a value of 0 for the VC space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

### 15.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding VC locations to transfer data for a specific VC. The logic managing the FIFO must be able to extract 32-bit values in-order for a specific VC upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the VC information to provide the rest of the data during the next read request(s).

The register `DSS.DSI_RX_FIFO_VC_SIZE` defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs should be taken into account. to change the size of the space of the memory allocated for a specific VC, the VC should be disabled by resetting the `DSS.DSI_VCn_CTRL[0]` VC\_EN bit to 0. The whole FIFO may not be used by the entire VC at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 15-64 indicates the corresponding values for the size of the space allocated in the FIFO:

**Table 15-64. Virtual Channel RX FIFO Size Values**

<code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_SIZE[x = 0, 3]</code>	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of RX FIFO is 128\*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128\*33 bits.

Table 15-65 indicates the start address of the space in the FIFO.

**Table 15-65. Virtual Channel RX FIFO Start Address**

<code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]</code>	Start Address
0	0
1	32
2	64
3	96
4	128

#### CAUTION

There must be no overlap of different VCs spaces.

While reading the received bytes in the RX FIFO, only the `DSS.DSI_VCn_SHORT_PACKET_HEADER` register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The `DSS.DSI_VCn_LONG_PACKET_HEADER` and `DSS.DSI_VCn_LONG_PACKET_PAYLOAD` registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and can not check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

### **15.5.4.10.3 Command Mode DMA Requests**

The DMA requests (DSI\_DMA\_REQ) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock (DSS\_L4\_ICLK) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. Users program the DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD and DSS.DSI\_VCn\_CTRL[26:24] DMA\_RX\_THRESHOLD bit fields for TX FIFO and RX FIFO respectively. The hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each VC should be a multiple of DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD bit field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request should be asserted. So the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER header register have been received, the DMA request is not asserted anymore even during the last transfer less than DMA\_TX\_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA\_TX\_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA should be programmed to read the exact number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register is performed until the DSS.DSI\_VCn\_CTRL[20] RX\_FIFO\_NOT\_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.DSI\_VCn\_CTRL[23:21] DMA\_TX\_REQ\_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.DSI\_VCn\_CTRL[29:27] DMA\_RX\_REQ\_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the VC ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the VC. Software users are responsible for parsing the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.DSI\_RX\_FIFO\_VC\_FULLNESS register. Then the system DMA can be programmed to read the exact number of bytes from the RX FIFO. The BTA interrupt (BTA\_IRQ) should be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user should read the DSS.DSI\_VCn\_IRQSTATUS[5] BTA\_IRQ status bit. The DMA request should not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the VC is expected to be overflow because the number of data to be received is greater than the space allocated for the VC, the previous programming model should be used. In place, the DMA request should be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

---

**Note:** To obtain best efficiency of the transfer the size of the request (read or write, single or burst) should be aligned with the threshold value.

---

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

#### 15.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultralow-power state (ULPS).

---

**Note:** The DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3 and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is to take latency at low TxClkEsc frequencies into account.

---

##### 15.5.4.11.1 Entering ULPS

To enter into ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.DSI\_COMPLEXIO\_CFG2[16] HS\_BUSY and DSS.DSI\_COMPLEXIO\_CFG2[17] LP\_BUSY bits to be reset to 0 and ensure that the DSS.DSI\_CLK\_CTRL[13] DDR\_CLK\_ALWAYS\_ON bit is 0.
2. TxUlpsClk state should change from inactive to active by setting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait for all TX\_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.DSI\_COMPLEXIO\_CFG2[16] HS\_BUSY bit is reset to 0 (in addition, for data lane #1, DSS.DSI\_COMPLEXIO\_CFG2[17] LP\_BUSY bit is reset to 0)
2. TxRequestEsc state should change from inactive to active by setting the DSS.DSI\_COMPLEXIO\_CFG2.LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

---

**Note:** When the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 and DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 bits are written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

---

##### 15.5.4.11.2 Exiting ULPS

To exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

2. Wait for the ULPSACTIVENOT\_ALL1\_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI\_COMPLEXIO\_IRQSTATUS[31] ULPSACTIVENOT\_ALL1\_IRQ status bit.
3. Start the wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

---

**Note:** When the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 and DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

---

To exit from ULPS for a clock lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO to OFF state by setting DSS.DSI\_COMPLEXIO\_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit for clock lane to INACTIVE state by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

---

**Note:** When the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 and DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

---

To exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT\_ALL1\_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI\_COMPLEXIO\_IRQSTATUS[31] ULPSACTIVENOT\_ALL1\_IRQ status bit.
3. Start the application wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxRequestEsc signals to INACTIVE state for the data lane by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

---

**Note:** When the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 and DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

---

To exit from ULPS for a data lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO into OFF state by setting DSS.DSI\_COMPLEXIO\_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxRequestEsc signals to INACTIVE state by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit to INACTIVE state by resetting the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

---

**Note:** When the DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG2 and DSS.DSI\_COMPLEXIO\_CFG2 LANEx\_ULPS\_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

---

When the sequence for entering/exiting into/from ULP state is started for specific lanes, users should wait for the completion of the sequence before changing the state of the same or other lanes.

#### 15.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

---

**Note:** When the VC is used to send video mode data from the video port, the DSS.DSI\_VCn\_CTRL[9] MODE\_SPEED and the DSS.DSI\_VCn\_CTRL[1] SOURCE bits are ignored.

---

##### 15.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the display controller with the timing parameters.
2. Configure the DSS.DSI\_VCn\_CTRL register as follows:
  - SOURCE bit is ignored by hardware
  - BTA\_LONG\_EN bit is set to 0: No BTA on long packet
  - BTA\_SHORT\_EN bit is set to 0: No BTA on short packet
  - MODE bit set to 1: The video mode is selected
  - MODE\_SPEED bit is ignored by hardware
3. Configure the DSS.DSI\_VM\_TIMING1 to DSS.DSI\_VM\_TIMING7 registers.
4. Set the ForceTxStopMode bit to 1 in the DSS.DSI\_TIMING1 register.
5. Enable the channel by setting the DSS.DSI\_VCn\_CTRL[0] VC\_EN bit to 1
6. Enable the module by setting the DSS.DSI\_CTRL[0] IF\_EN bit to 1.
7. Poll the ForceTxStopMode bit to 0 in the DSS.DSI\_TIMING1 register.
8. Enable the LCD video output by setting the DSS.DISPC\_CONTROL[0] LCDENABLE bit to 1

#### CAUTION

The restriction for stopping the video mode is that no frame should be sent by the display controller (DISPC) after disabling video mode in DSI.

##### 15.5.4.12.2 Command Mode Transfer Example 1

#### CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI\_VCn\_CTRL register as follows:
  - SOURCE bit set to 0: The source is the L4 interconnect port
  - BTA\_LONG\_EN bit is set to 0: No automatic BTA on long packet
  - BTA\_SHORT\_EN bit is set to 0: No automatic BTA on short packet
  - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI\_VCn\_IRQENABLE[2] PACKET\_SENT\_IRQ\_EN bit to 1
3. Set the ForceTxStopMode bit to 1 in the DSS.DSI\_TIMING1 register.
4. Enable the channel by setting the DSS.DSI\_VCn\_CTRL[0] VC\_EN bit to 1
5. Enable the module by setting the DSS.DSI\_CTRL[0] IF\_EN bit to 1
6. Poll the ForceTxStopMode bit to 0 in the DSS.DSI\_TIMING1 register.
7. For long packet:
  - Write the header value into the DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register
  - Write the data into the DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register for the full payload. Repeat step until WC is reached (see DSI\_VCn\_LONG\_PACKET\_HEADER)
 For the short packet:
  - Send short packets through the L4 interconnect: Write the header value into the DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register. Repeat step for each short packet.
8. Send one or more packets through L4 interconnect:
  - Write the header value into DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register
  - Write the data into DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register for the full payload.
  - Repeat step 5 for all the long packets
9. Send short packets through L4 interconnect:
  - Write the header value into DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER register
  - Repeat step 6 for all the short packets
10. Interrupt routine: Wait for PACKET\_SENT\_IRQ interrupt generation by polling the DSS.DSI\_VCn\_IRQSTATUS[2] PACKET\_SENT\_IRQ status bit and notify the application software when received.
11. The applicative software forces the bus turn-around:
  - Wait until the PACKET\_SENT\_IRQ has happened as many times as the number of sent packets
  - Set the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit to 1 to send manually a BTA
  - Wait until the DSS.DSI\_VCn\_CTRL[6] BTA\_EN bit is reset to 0 by hardware
12. Receive the packets from the peripheral
  - Start polling the DSS.DSI\_VCn\_CTRL[20] RX\_FIFO\_NOT\_EMPTY status bit
  - Whenever the RX\_FIFO\_NOT\_EMPTY bit equals to 1, read one word in the RX FIFO

### 15.5.4.12.3 Command Mode Transfer Example 2

#### CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.DSI\_VCn\_CTRL register as follows:
  - SOURCE bit set to 0: The source is the L4 interconnect port
  - BTA\_LONG\_EN bit is set to 1: Automatic BTA on long packet
  - BTA\_SHORT\_EN bit is set to 1: Automatic BTA on short packet
  - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI\_VCn\_IRQENABLE[2] PACKET\_SENT\_IRQ\_EN bit to 1

3. Set the ForceTxStopMode bit to 1 in DSS.DSI\_TIMING1 register.
4. Enable the channel by setting the DSS.DSI\_VCn\_CTRL[0] VC\_EN bit to 1
5. Configure the TX FIFO threshold and DMA requests parameters:
  - Program the DSS.DSI\_VCn\_CTRL[19:17] DMA\_TX\_THRESHOLD bit field
  - Program the DSS.DSI\_VCn\_CTRL[23:21] DMA\_TX\_REQ\_NB bit field
6. Program the system DMA to be ready to send data to the L4 interconnect port
7. Enable the module by setting the DSS.DSI\_CTRL[0] IF\_EN bit to 1
8. Poll the ForceTxStopMode bit to 0 in DSS.DSI\_TIMING1 register.
9. Write the header value into DSS.DSI\_VCn\_LONG\_PACKET\_HEADER register
10. Interrupt routine: Wait for PACKET\_SENT\_IRQ interrupt generation by polling the DSS.DSI\_VCn\_IRQSTATUS[2] PACKET\_SENT\_IRQ status bit and notify the application software when received.
11. Receive the packets from the peripheral
  - Start polling the DSS.DSI\_VCn\_CTRL[20] RX\_FIFO\_NOT\_EMPTY status bit
  - Whenever the RX\_FIFO\_NOT\_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO
12. Repeat the steps 7 for all long packets.

### **15.5.5 DSI PLL Controller Basic Programming Model**

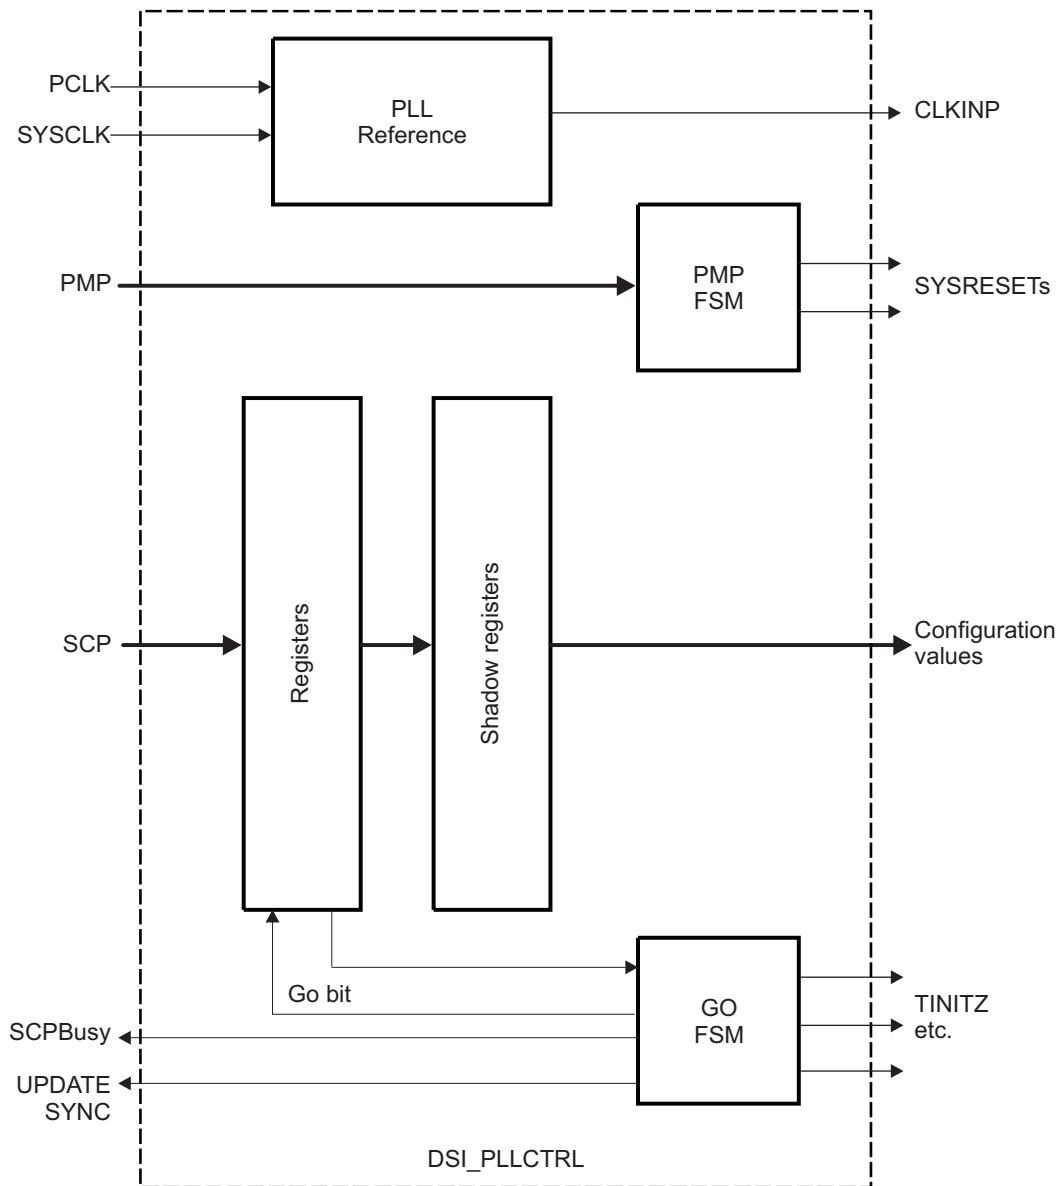

#### **15.5.5.1 Software Reset**

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, software users can monitor the reset status of the DSI PLL control module by reading the DSS.DSI\_PLL\_STATUS[0] DSI\_PLLCTRL\_RESET\_DONE status bit.

### 15.5.5.2 DSI PLL Programming Blocks

Figure 15-138 shows the DSI PLL programming blocks.

Figure 15-138. DSI PLL Programming Blocks

dss-181

### 15.5.5.3 DSI PLL Go Sequence

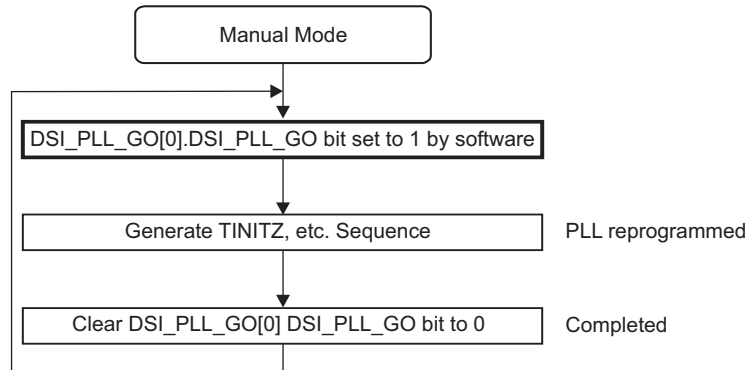

In Manual Mode (DSS.DSI\_PLL\_CONTROL[0] DSI\_PLL\_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit should be set. The appropriate sequence should then be sent on the TINITZ, TENABLE & TENABLEDIV pins, respecting the timing requirements of the ADPLLV2. The DSS.DSI\_PLL\_GO[0] DSI\_PLL\_GO bit will be cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module, so that will be programmed at the same time. In this mode, the software should deassert CLKINEN by unsetting the DSS.DSI\_PLL\_CONFIGURATION2[14] DSI\_PHY\_CLKINEN to 0 and to assert HSDIVBYPASS correctly by setting the DSS.DSI\_PLL\_CONFIGURATION2[20] DSI\_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DSI\_PHY and display subsystem during PLL locking. In manual mode the shadow register should be updated anyway so that valid values are present when later selecting automatic mode.

Figure 15-139 shows the DSI PLL Go flowchart in manual mode (DSS.DSI\_PLL\_CONTROL[0] DSI\_PLL\_AUTOMODE bit set to 0).

**Figure 15-139. DSI PLL Go Sequence (Manual Mode)**

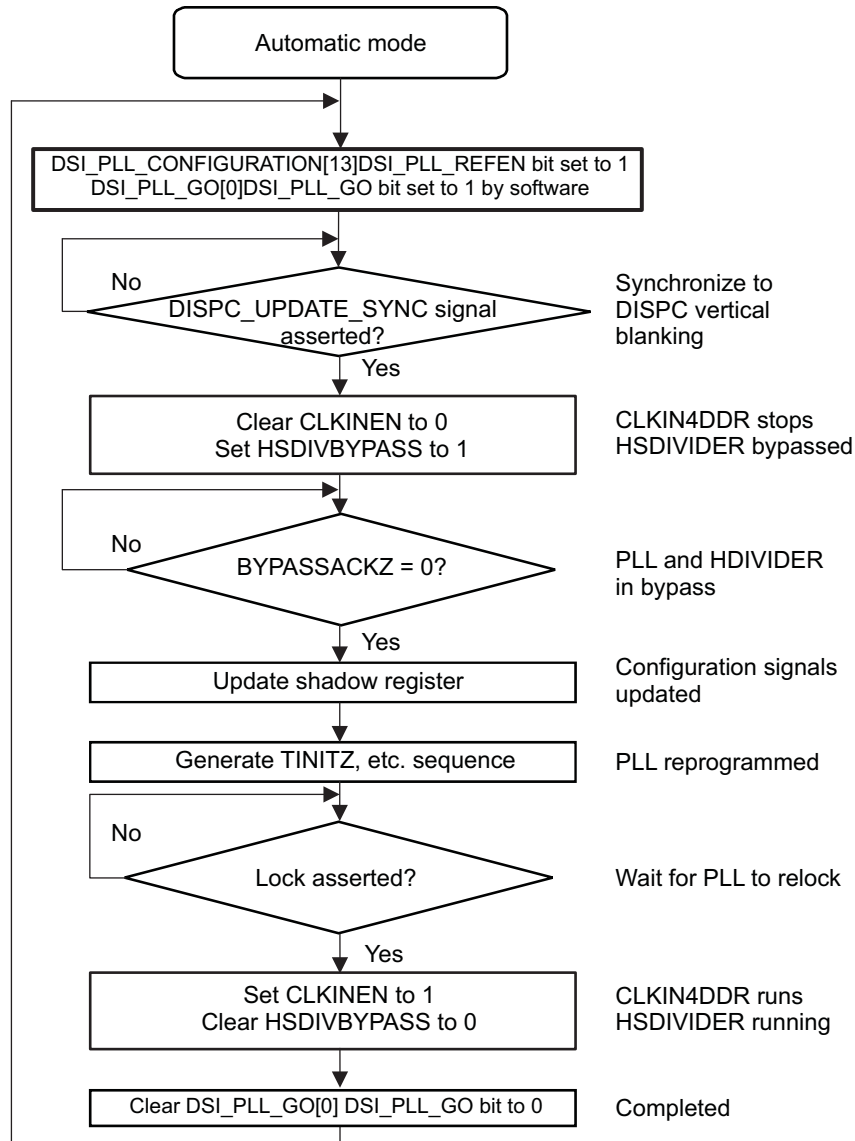

dss-182

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic Mode (DSS.DSI\_PLL\_CONTROL[0] DSI\_PLL\_AUTOMODE bit set to 1), the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DSI\_PLL\_CONFIGURATION2 register will be deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN will be controlled automatically and the register value is overridden.

Figure 15-140 shows the DSI PLL Go flowchart in automatic mode (DSS.DSI\_PLL\_CONTROL[0] DSI\_PLL\_AUTOMODE bit set to 1).

Figure 15-140. DSI PLL Go Sequence (Automatic Mode)

dss-183

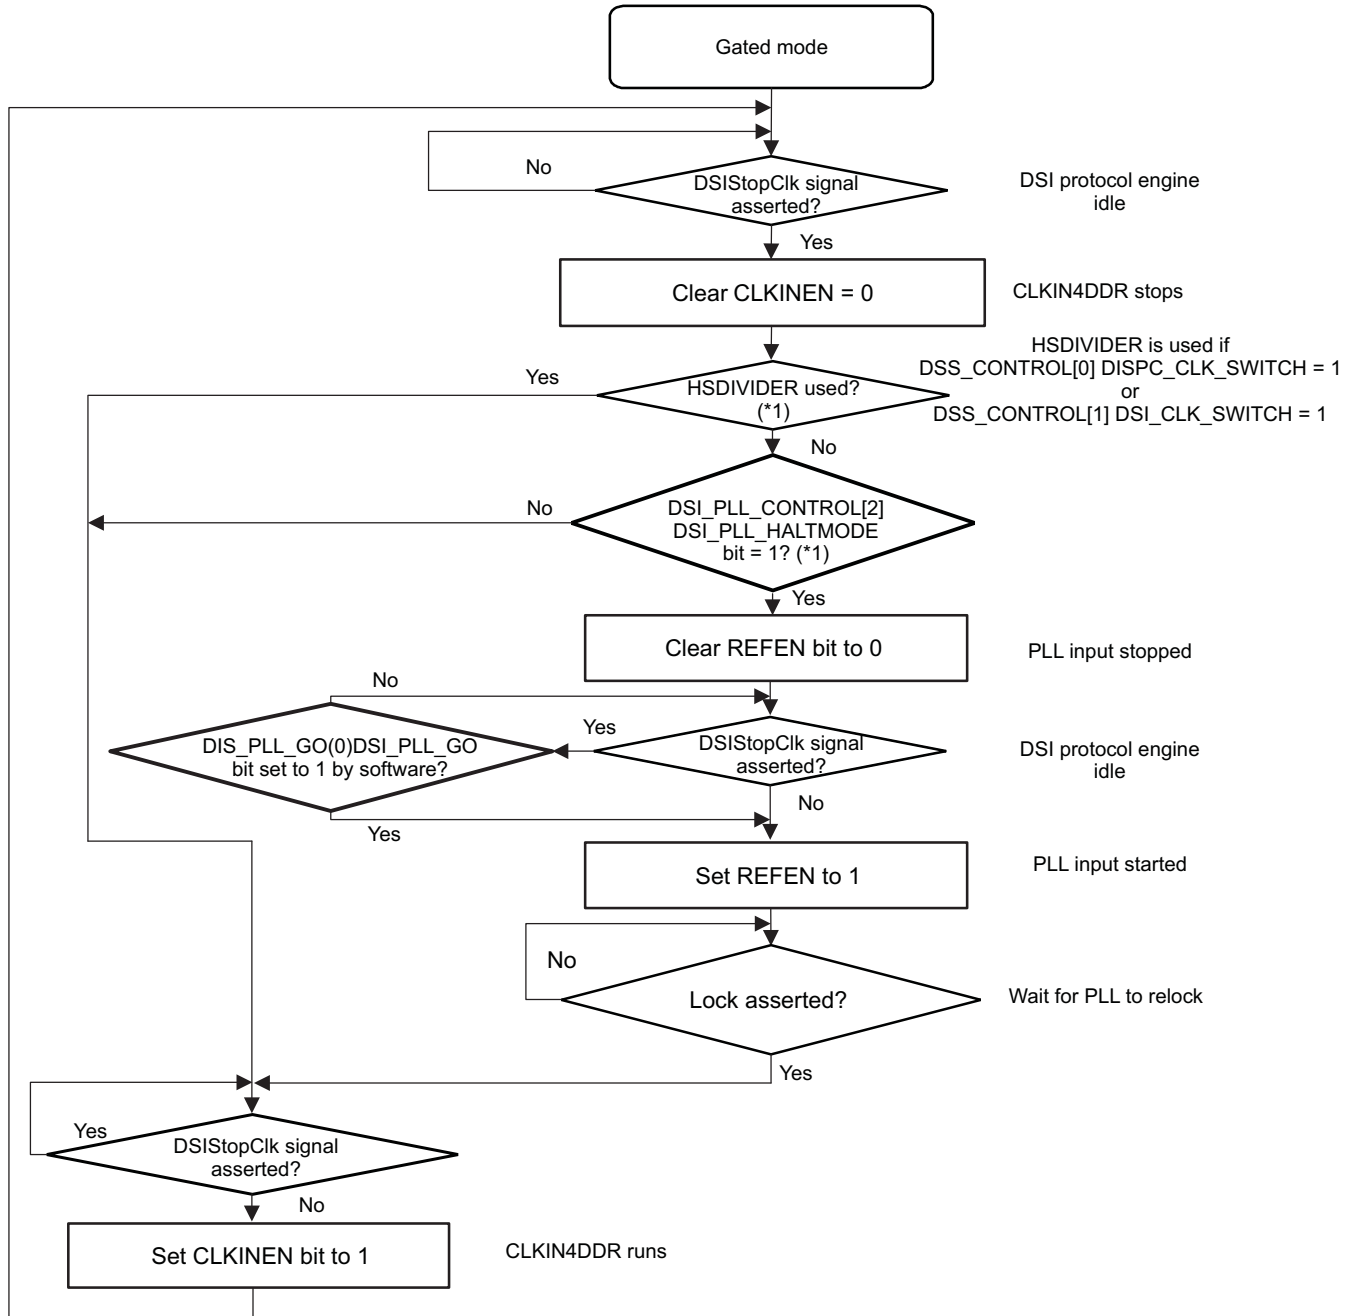

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

#### 15.5.5.4 DSI PLL Clock Gating Sequence

Clock gating may be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, then the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstarted by inspecting the LOCK signal (DSS.DSI\_PLL\_STATUS[1] DSI\_PLL\_LOCK status bit). Since TxByteClkHS is stopped when CLKIN4DDR is stopped, this should obviate the need for any explicit feedback that the clock has been unstarted in the other case. This flow chart should run even if the DSS.DSI\_PLL\_GO[0] DSI\_PLL\_GO bit has not been set.

Figure 15-141 shows the DSI PLL gated mode sequence.

**Figure 15-141. Gated Mode Sequence**

NOTE: All thick-outlined blocks show operations performed by software.

dss-184

### 15.5.5.5 DSI PLL Lock Sequence

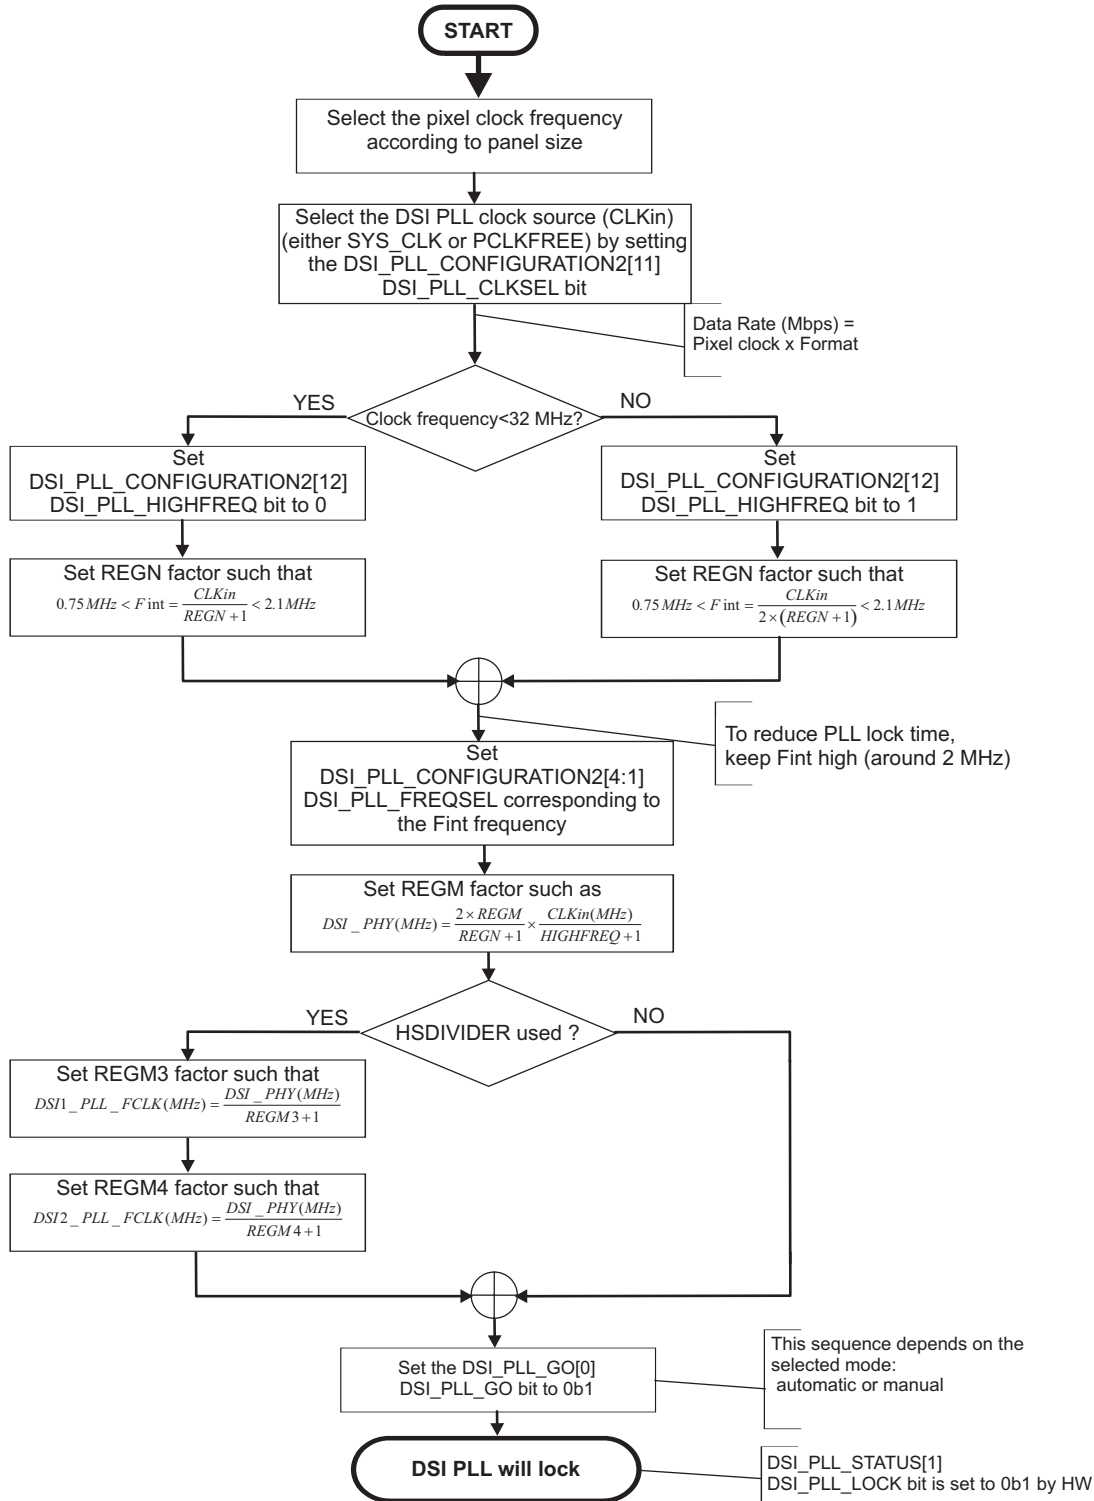

The DSI PLL (ADPLLv2) generates CLKIN4DDR. The HSDIVIDER generates two clocks: DSI1\_PLL\_FCLK connected to the display controller (DISPC) and the DSI2\_PLL\_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

CLKIN4DDR is twice the data rate and four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by DSS.DSI\_PLL\_CONFIGURATION1[18:8] DSI\_PLL\_REGM bit field
- REGN factor is programmed by DSS.DSI\_PLL\_CONFIGURATION1[7:1] DSI\_PLL\_REGN bit field
- REGM3 factor is programmed by DSS.DSI\_PLL\_CONFIGURATION1[22:19] DSI\_CLOCK\_DIV bit field
- REGM4 factor is programmed by DSS.DSI\_PLL\_CONFIGURATION1[26:23] DSIPROTO\_CLOCK\_DIV bit field

Figure 15-142 shows the programming sequence.

Figure 15-142. DSI PLL Programming Sequence

dss-190

**Notes:**

- The REGM3 and REGM4 factors must according with the following conditions:
  - The DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK frequencies must be a multiple of the PCLK frequency (for proper settings of PCD and LCD factors in the DISPC)
  - The DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK frequencies must be lower than 173 MHz
- Most of the other DSI PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See [Section 15.5.5.7](#) for details on DSI PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is  $30 \times 18 = 540$  Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS\_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL to 0b0.

Set the DSS.DSI\_PLL\_CONFIGURATION2[12] DSI\_PLL\_HIGHFREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI\_PLL\_CONFIGURATION1[7:1] DSI\_PLL\_REGN bit field to 0xC and set DSI\_PLL\_CONFIGURATION2[4:1] DSI\_PLL\_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

To get CLKIN4DDR to 1080 MHz, set the REGM factor to 270 by setting the DSS.DSI\_PLL\_CONFIGURATION1[18:8] DSI\_PLL\_REGM to 0x10E.

$CLKIN4DDR = 2 \times 270/13 \times 26/1 = 1080$  MHz

Since DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.DSI\_PLL\_CONFIGURATION1[22:19] DSS\_CLOCK\_DIV bit field and DSS.DSI\_PLL\_CONFIGURATION1[26:23] DSIPROTO\_CLOCK\_DIV to 0xB:

$DSI1\_PLL\_FCLK = DSI2\_PLL\_FCLK = 1080/12 = 90$  MHz

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format  
The data rate is  $(60 \times 16)/2 = 480$  Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

The frequency on the clock lane is 240 MHz (960 divided by 4).

The SYS\_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI\_PLL\_CONFIGURATION2[11] DSI\_PLL\_CLKSEL bit to 0b0.

Set the DSS.DSI\_PLL\_CONFIGURATION2[12] DSI\_PLL\_HIGHFREQ bit to 0b0 as the source clock frequency (SYS\_CLK in this example) is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI\_PLL\_CONFIGURATION1[7:1] DSI\_PLL\_REGN bit field to 0xC and set DSI\_PLL\_CONFIGURATION2[4:1] DSI\_PLL\_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

To get CLKIN4DDR to 960 MHz, set the REGM factor to 240 by setting the DSS.DSI\_PLL\_CONFIGURATION1[18:8] DSI\_PLL\_REGM to 0x0F0.

$CLKIN4DDR = 2 \times 240/13 \times 26/1 = 960$  MHz

Since DSI1\_PLL\_FCLK and DSI2\_PLL\_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.DSI\_PLL\_CONFIGURATION1[22:19] DSS\_CLOCK\_DIV bit field and DSS.DSI\_PLL\_CONFIGURATION1[26:23] DSIPROTO\_CLOCK\_DIV to 0x7:

$DSI1\_PLL\_FCLK = DSI2\_PLL\_FCLK = 960/8 = 120$  MHz

### 15.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI\_PLL\_STATUS[1] DSI\_PLL\_LOCK status bit gives the DSI PLL lock state.
  - The DSS.DSI\_PLL\_STATUS[2] DSI\_PLL\_RECAL status bit informs if the PLL must be uncalibrated
- These signals can also generate interrupts at DSI protocol engine level:

- - DSS.DSI\_IRQSTATUS[9], PLL\_RECAL\_IRQ bit
  - DSS.DSI\_IRQSTATUS[8] PLL\_UNLOCK\_IRQ
  - DSS.DSI\_IRQSTATUS[7] PLL\_LOCK\_IRQ
- The PLL\_LOCK\_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.DSI\_IRQSTATUS[7] PLL\_LOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_UNLOCK\_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.DSI\_IRQSTATUS[8] PLL\_UNLOCK\_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL\_RECAL\_IRQ interrupt indicates that the DSI PLL must be recalibrated. To monitor this event, read the DSS.DSI\_IRQSTATUS[9] PLL\_RECAL\_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored :

- The DSS.DSI\_PLL\_STATUS[3] DSI\_PLL\_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.DSI\_PLL\_STATUS[4] DSI\_PLL\_LIMP status bit informs about the DSI PLL limp status.

### 15.5.5.7 DSI PLL Recommended Values

Table 15-66 shows the DSI PLL recommended values.

**Table 15-66. Recommended Programming Values**

Field Name	Value	Description
DSI_HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_HALTMODE	-	See Section 15.5.5.4 for details
DSI_PLL_GATEMODE	-	See Section 15.5.5.4 for details
DSI_PLL_AUTOMODE	-	See Section 15.5.5.4 for details
DSI_PLL_GO	1->0	Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed
DSIPROTO_CLOCK_DIV	See <sup>(1)</sup>	DSI protocol engine clock divider
DSS_CLOCK_DIV	See <sup>(1)</sup>	DSS clock divider
DSI_PLL_REGM	See <sup>(1)</sup>	Feedback clock divider
DSI_PLL_REGN	See <sup>(1)</sup>	Reference clock divider
DSI_PLL_STOPMODE	1	Required to use GATEMODE bit
DSI_HSDIVBYPASS	0	PLL is controlling HSDIVIDER bypass
DSI_PROTO_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PROTO_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSS_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSS clock source
DSS_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSS clock source

<sup>(1)</sup> The bit field value should be set according to the desired clock frequency.

**Table 15-66. Recommended Programming Values (continued)**

Field Name	Value	Description
DSI_BYPASSEN	0	To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit should be set to 1
DSI_PHY_CLKINEN	1	Enable CLKIN4DDR
DSI_PLL_REFEN	1	Enable PLL reference
DSI_PLL_HIGHFREQ	0/1	Set to 1 if the clock reference is higher than 32 MHz (21 MHz if <a href="#">DSS.DSI_PLL_CONFIGURATION1[7:1]</a> DSI_PLL_REGN = 0)
DSI_PLL_CLKSEL	0/1	Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK.
DSI_PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt should be used to decide when to perform a PLL uncalibration No automatic uncalibration will be performed
DSI_PLL_TIGHTPHASELOCK	0	Normal criteria
DSI_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time
DSI_PLL_PLLLPMODE	0	Normal operation For smaller display sizes may be possible to set to 1
DSI_PLL_FREQSEL	See <sup>(1)</sup>	Must be set according to the PLL internal reference frequency (after N divider) See register descriptions for values
DSI_PLL_IDLE	0	PLL active

## 15.5.6 DSI Complex I/O Basic Programming Model

### 15.5.6.1 Software Reset

The clock domain using the TxByteClkHS from the DSI complex I/O has dedicated reset done information in the [DSS.DSI\\_COMPLEXIO\\_CFG1\[29\]](#) RESET\_DONE bit. The [DSS.DSI\\_SYSCONFIG\[1\]](#) SOFT\_RESET bit is used to reset the TxByteClkHS power domain. A dummy read using the SCP interface to any DSI\_PHY register is required after DSI\_PHY reset to complete the reset of the DSI complex I/O.

### 15.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in [DSS.DSI\\_PHY\\_CFG5](#) register:

- [DSS.DSI\\_PHY\\_CFG5\[31\]](#) RESETDONETXBYTECLK bit : Reset done for the TXBYTECLK domain.
- [DSS.DSI\\_PHY\\_CFG5\[28:26\]](#) RESETDONETXCLKESC<sub>i</sub> bits: Reset done for the TXCLKESC domain for lane *i* (*i* between 0 and 2).
- [DSS.DSI\\_PHY\\_CFG5\[30\]](#) RESETDONESCPCCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the RESETDONESCPCCLK signal goes high and software users can read again the [DSS.DSI\\_PHY\\_CFG5\[30\]](#) RESETDONESCPCCLK bit to ensure that

the value is now 1.

**Note:** The software should not write in the DSI\_PHY\_SCP registers before the DSS.DSI\_PHY\_CFG5[30] RESETDONESCPCCLK bit is set to 1.

- DSS.DSI\_PHY\_CFG5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state machine is complete when the RESETDONEPWRCLK signal goes high.

### 15.5.6.3 Pad Configuration

The number of lanes is configurable through the DSS.DSI\_COMPLEXIO\_CFG1 register.

It is not allowed to change on the fly the position (by modifying the DATA<sub>i</sub>\_POSITION with  $i=1$  or  $2$  and CLOCK\_POSITION bit fields), P/N order (Positive/Negative order of the differential pair by modifying the DATA<sub>i</sub>\_POL with  $i=1$  or  $2$  and CLOCK\_POL) or number of active data lanes (by modifying the DSS.DSI\_COMPLEXIO\_CFG1[10:8] DATA2\_POSITION bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the DSS.DSI\_COMPLEXIO\_CFG1[10:8] DATA2\_POSITION bit reset value is 0).

### 15.5.6.4 Display Timing Configuration

Depending on the CLKIN4DDR frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI complex I/O registers.

#### 15.5.6.4.1 High-Speed Clock Transmission

Figure 15-143 shows an example of high-speed Clock Transmission.

**Figure 15-143. High-Speed Clock Transmission**

dss-185

TXByteClkHS is an output clock which is derived by dividing the CLKIN4DDR clock by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI\_PHY\_CFG1[22:16] TLPX\_HALF bit field.
  - THS-PREPARE timing is programmed by the DSS.DSI\_PHY\_CFG0[31:24] THS\_PREPARE bit field.
  - TCLK-ZERO timing is programmed by the DSS.DSI\_PHY\_CFG1[7:0] TCLK\_ZERO bit field.
- . TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSI\_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSI\_PHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.DSI\_PHY\_CFG1[15:8] TCLK\_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI\_PHY\_CFG0[7:0] THS\_EXIT bit field.

The DSI\_PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

It is requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

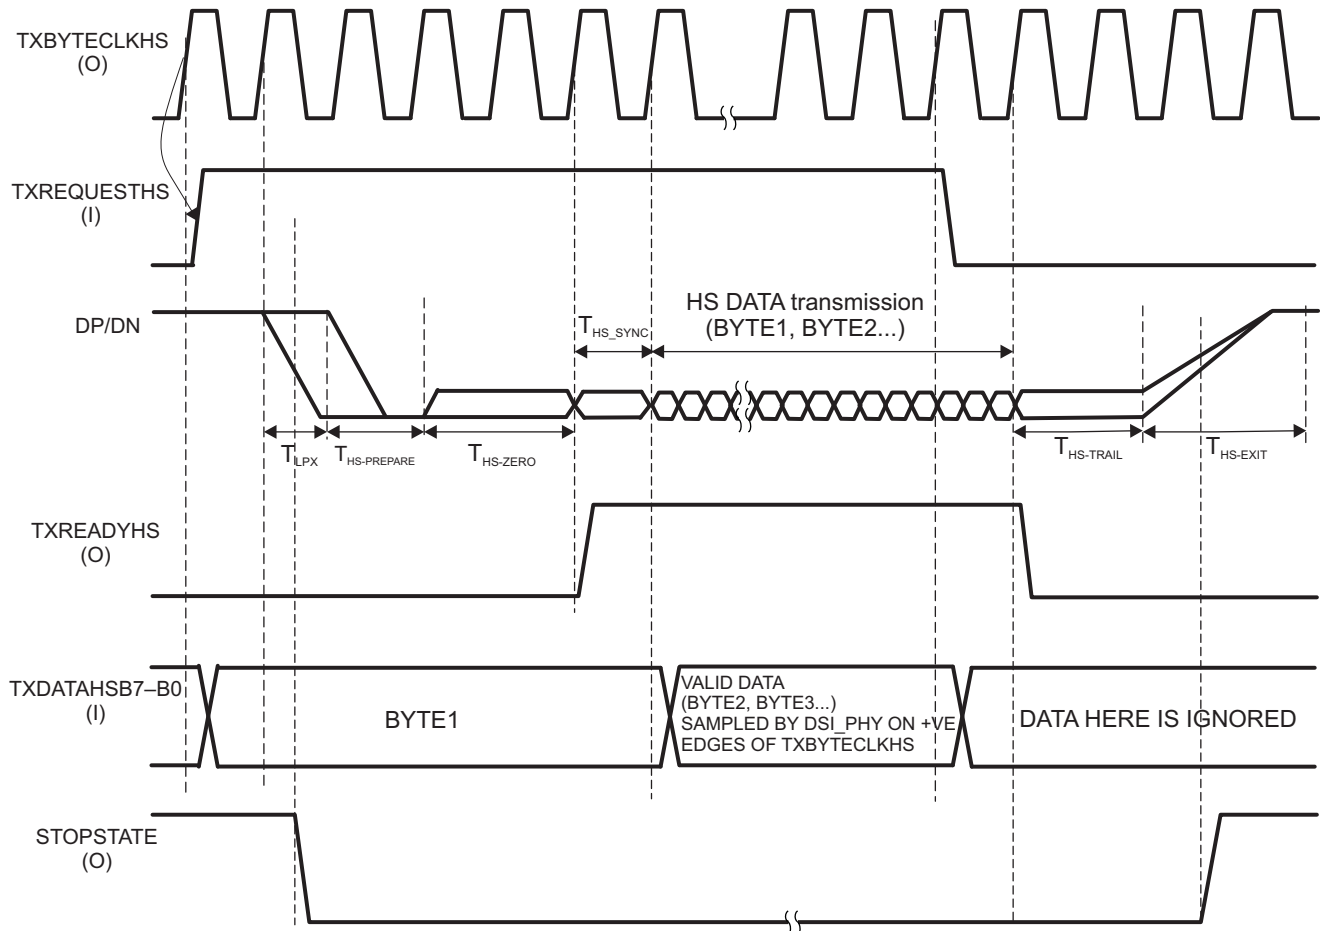

CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Tbyteclk periods after TxRequestHS falling edge is received by DSI\_PHY.

The DSI protocol engine should ensure that TXREQUESTESC, TXULPSCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

### 15.5.6.4.2 High-Speed Data Transmission

Figure 15-144 shows an example of high-speed Data Transmission.

**Figure 15-144. High-Speed Data Transmission**

dss-186

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI\_PHY\_CFG1[22:16] TLPX\_HALF bit field.
  - THS-PREPARE + THS-ZERO timing is programmed by the DSS.DSI\_PHY\_CFG0[23:16] THS\_PREPARE\_THS\_ZERO bit field.
- . THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is eight high-speed bits.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and programmed by the following register bit fields:

- THS-TRAIL timing is programmed by the DSS.DSI\_PHY\_CFG0[15:8] THS\_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI\_PHY\_CFG0[7:0] THS\_EXIT bit field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

The Protocol should ensure that TXREQUESTESC, TXULPCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

#### **15.5.6.4.3 Other DSI\_PHY Transmission and Reception**

The timing of the following sequences defined in the DSI\_PHY protocol cannot be programed by users:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP state command transmission on data lanes
- ULP state transmission on clock lane
- Turn-around request in transmit mode
- Turn-around request in receive mode
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP state command on clock lane in receive mode
- ULP state command on data lane in receive mode

#### **15.5.6.5 Error Handling**

A dedicated register for the DSI complex I/O, DSS.DSI\_COMPLEXIO\_IRQSTATUS, indicates the state of each error provided by the DSI complex I/O error signals. The DSI\_PHY reports the following errors:

- DSS.DSI\_COMPLEXIO\_IRQSTATUS[7:5] ERR\_ESCi\_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSS.DSI\_COMPLEXIO\_IRQSTATUS[2:0] ERRSYNCESCi\_IRQ: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESC is made high and remains high until the next change in line state.
- DSS.DSI\_COMPLEXIO\_IRQSTATUS[12:10] ERRCONTROLi\_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSS.DSI\_COMPLEXIO\_IRQSTATUS ERRCONTENTIONLP0\_i\_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- DSS.DSI\_COMPLEXIO\_IRQSTATUS ERRCONTENTIONLP1\_i\_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the DSS.DSI\_COMPLEXIO\_IRQSTATUS[30] ULPSACTIVENOT\_ALL0\_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSS.DSI\_COMPLEXIO\_IRQSTATUS[31] ULPSACTIVENOT\_ALL1\_IRQ event is generated.

When any of the events defined in DSS.DSI\_COMPLEXIO\_IRQSTATUS register happened, the DSS.DSI\_IRQSTATUS[10] COMPLEXIO\_ERR\_IRQ bit is set to 1 at DSI protocol engine level.

The software must take appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral through reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

### 15.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

#### 15.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.DISPC\_CONTROL[11] STALLMODE bit. The DSS.DISPC\_CONTROL[5] GOLCD bit should not be set to 1 but the display controller configuration (DMA engine, pipelines associated to the LCD output,...) should be set before enabling the LCD output by setting the DSS.DISPC\_CONTROL[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC\_CONTROL[16] FIFOHANDCHECK should be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It should be disabled before resetting the DSS.DISPC\_CONTROL[11] STALLMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

---

**Note:** The LCD output is disabled at the end of the transfer of the frame. The software must reenble the LCD output to generate a new frame by setting the DSS.DISPC\_CONTROL[0] LCDENABLE to 1. See [Figure 15-145](#).

---

#### 15.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI\_CONTROL
- DSS.RFBI\_PIXEL\_CNT
- DSS.RFBI\_LINE\_NUMBER

##### 15.5.7.2.1 High Threshold

The DSS.RFBI\_CONTROL[6:5] HIGHTHRESHOLD bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register [RFBI\\_DATA](#). It should be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI\_CONTROL[7] DISABLE\_DMA\_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the [RFBI\\_DATA](#) location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI\_CONTROL[7] DISABLE\_DMA\_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

**Note:** Software users can access the [RFBI\\_DATA](#) location without using the DMA request and without programming the high threshold value (backward mode).

### 15.5.7.2.2 Bypass Mode

Setting the `DSS.RFBI_CONTROL[1]` `BYPASSMODE` bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

### 15.5.7.2.3 Enable

Setting/resetting the `DSS.RFBI_CONTROL[0]` `ENABLE` bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The `DSS.RFBI_PIXEL_CNT[31:0]` `PIXELCNT` bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

**Table 15-67. RFBI Behavior**

<code>RFBI_CONTROL[1]</code> <code>BYPASSMODE</code> bit value	<code>RFBI_CONTROL[0]</code> <code>ENABLE</code> bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

**Note:** The LCD output is disabled at the end of the transfer of the frame. The software must reenble the LCD output to generate a new frame by setting the `DSS.DISPC_CONTROL[0]` `LCDENABLE` to 1. See [Figure 15-145](#).

### 15.5.7.2.4 Configuration Selection

Setting the `DSS.RFBI_CONTROL[3:2]` `CONFIGSELECT` bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the `RFBI_CS1` signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only `RFBI_CS0` is asserted to read data from the device connected on `RFBI_CS0`. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

### 15.5.7.2.5 ITE Bit

Set the `DSS.RFBI_CONTROL[4]` `ITE` bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the `STALL` mode to account for the `RFBI_DISPC_STALL` signal. Setting the trigger mode to external (`DSS.RFBI_CONFIG[3:2]` `TRIGGERMODE` bit field set to 0x1 or 0x2) causes the `DSS.RFBI_CONTROL[4]` `ITE` bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The `RFBI_DISPC_STALL` signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached

- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.RFBI\_CONTROL[0] ENABLE bit reset to 0x0

The RFBI\_DISPC\_STALL signal is deasserted when the DSS.RFBI\_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI\_CONTROL[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

#### 15.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI\_PIXEL\_CNT[31:0] PIXELCNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI\_CONTROL[0] ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI\_CONTROL[0] ENABLE bit is set and a new value is written in the DSS.RFBI\_PIXEL\_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if DSS.RFBI\_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3 and DSS.RFBI\_CONFIGi[8:7] L4FORMAT is equal to 0x0, an even number of write accesses to the data register should be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When DSS.RFBI\_CONFIGi[10:9] CYCLEFORMAT bit field is 0x3 - meaning that 2 pixels are sent over 3 cycles -, the number of pixels to be programmed in the DSS.RFBI\_PIXEL\_CNT[31:0] PIXELCNT bit field should be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI\_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3, DSS.RFBI\_CONFIGi[8:7] L4FORMAT is equal to 0, and back to back register write is processed, the following registers should be written after the first data: RFBI\_CMD, RFBI\_PARAM, RFBI\_READ, and RFBI\_STATUS. The whole data transfer should first be performed before being able to write to any other registers (RFBI\_CMD, RFBI\_PARAM, RFBI\_READ, and RFBI\_STATUS).

#### 15.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, the hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

#### 15.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI\_SYSCONFIG
- DSS.RFBI\_SYSSTATUS
- DSS.RFBI\_CONFIG0 (configuration 0) and DSS.RFBI\_CONFIG1 (configuration 1)
- DSS.RFBI\_VSYNC\_WIDTH
- DSS.RFBI\_HSYNC\_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI\_CONTROL[3:2] CONFIGSELECT bit field).

### 15.5.7.3.1 Parallel Mode

The DSS.RFBI\_CONFIG<sub>i</sub>[1:0]PARALLELMODE bit field (with  $i = 0, 1$ ) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

### 15.5.7.3.2 Trigger Mode

Setting the DSS.RFBI\_CONFIG[3:2]TRIGGERMODE bit field configures the trigger on the external TE signal (RFBI\_TE\_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI\_CONTROL[4] ITE bit.

### 15.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI\_VSYNC\_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

### 15.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI\_HSYNC\_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

### 15.5.7.3.5 Cycle Format

Setting the DSS.RFBI\_CONFIG<sub>i</sub>[10:9] CYCLEFORMAT bit field (with  $i = 0, 1$ ) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI\_DATA\_CYCLE<sub>i</sub> (if DSS.RFBI\_CONFIG[10:9] CYCLEFORMAT bit field = 00) only  
or
- DSS.RFBI\_DATA\_CYCLE1<sub>i</sub> and DSS.RFBI\_DATA\_CYCLE2<sub>i</sub> (if DSS.RFBI\_CONFIG[10:9] CYCLEFORMAT bit field = 01)  
or
- DSS.RFBI\_DATA\_CYCLE1<sub>i</sub>, DSS.RFBI\_DATA\_CYCLE2<sub>i</sub>, and DSS.RFBI\_DATA\_CYCLE3<sub>i</sub> (if DSS.RFBI\_CONFIG[10:9] CYCLEFORMAT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI\_DATA\_CYCLE<sub>i</sub> registers.

### 15.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI\_CONFIG<sub>i</sub>[12:11] UNUSEDBITS bit field (with  $i = 0, 1$ ) is used.

### 15.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI\_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the DSS.RFBI\_CONFIG<sub>i</sub>[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 15-68](#) for the bits configuration values.

- Chip-select assertion/deassertion time

RFBI\_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:

DSS.RFBI\_ONOFF\_TIMEi[3:0] CSONTIME bit field (with i = 0, 1).

The chip-select deassertion time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[9:4] CSOFFTIME bit field (with i = 0, 1)

#### CAUTION

Configuring DSS.RFBI\_ONOFF\_TIMEi[3:0] CSONTIME = DSS.RFBI\_ONOFF\_TIMEi[9:4] CSOFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

DSS.RFBI\_CYCLE\_TIMEi[17:12] CSPULSEWIDTH bit field (with i = 0, 1)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The DSS.RFBI\_CYCLE\_TIMEi [19] RRENABLE bit: Read-to-read access
- The DSS.RFBI\_CYCLE\_TIMEi [20] WWENABLE bit: Write-to-write access
- The DSS.RFBI\_CYCLE\_TIMEi [18] RWENABLE bit: Read-to-write access
- The DSS.RFBI\_CYCLE\_TIMEi [21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:

DSS.RFBI\_CYCLE\_TIMEi[27:22] ACCESSTIME bit field (with i = 0, 1)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI\_ONOFF\_TIMEi[29:24] REOFFTIME, with i = 0, 1).

- Write enable cycle time

The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:

The DSS.RFBI\_CYCLE\_TIMEi[5:0] WECYCLETIME bit field (with i = 0, 1)

- Write enable assertion/deassertion time

The WE assertion delay time from start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[13:10] WEONTIME bit field (with i = 0, 1)

The WE deassertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[19:14] WEOFFTIME bit field (with i = 0, 1)

- Read enable cycle

The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:

The DSS.RFBI\_CYCLE\_TIMEi[11:6] RECYCLETIME bit field (with i = 0, 1)

- Read enable assertion/deassertion time

The RE assertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[23:20] REONTIME bit field (with i = 0, 1)

The RE deassertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[29:24] REOFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI\_CSi, RFBI\_WE, and RFBI\_RE, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the `DSS.RFBI_CYCLE_TIME`<sub>*i*</sub>[17:12] `CSPULSEWIDTH` bit field = 0, with *i* = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (`RFBI_CS`<sub>*i*</sub>, `RFBI_WE`, and `RFBI_RE`, with *i* = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 15-68 summarizes the configurations values for each timing bit.

**Table 15-68. RFBI Timings Configuration**

Configuration bits <sup>(1)</sup>	Granularity <sup>(2)</sup>	
	one	two
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[3:0]</sub> <code>CSONTIME</code>	0 to 15	0 to 30
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[9:4]</sub> <code>CSOFFTIME</code>	0 to 63	0 to 126
<code>DSS.RFBI_CYCLE_TIME</code> <sub><i>i</i></sub> [17:12] <code>CSPULSEWIDTH</code>	0 to 63	0 to 126
<code>DSS.RFBI_CYCLE_TIME</code> <sub>[27:22]</sub> <code>ACCESSTIME</code>	0 to 63	0 to 126
<code>DSS.RFBI_CYCLE_TIME</code> <sub>[5:0]</sub> <code>WECYCLETIME</code>	0 to 63	0 to 126
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[13:10]</sub> <code>WEONTIME</code>	0 to 15	0 to 30
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[19:14]</sub> <code>WEOFFTIME</code>	0 to 63	0 to 126
<code>DSS.RFBI_CYCLE_TIME</code> <sub>[11:6]</sub> <code>RECYCLETIME</code>	0 to 63	0 to 126
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[23:20]</sub> <code>REONTIME</code>	0 to 15	0 to 30
<code>DSS.RFBI_ONOFF_TIME</code> <sub>[29:24]</sub> <code>REOFFTIME</code>	0 to 63	0 to 126

<sup>(1)</sup> Where *i* = 0 or 1.

<sup>(2)</sup> Number of L4Clk cycles. The granularity can be configured using the `DSS.RFBI_CONFIG`<sub>*i*</sub>[4] `TIMEGRANULARITY` bit.

### 15.5.7.3.8 RFBI State-Machine

Referring to Table 15-37, the signals `RFBI_A0`, `RFBI_RE`, and `RFBI_WE` are asserted/deasserted based on the register accessed (`DSS.RFBI_CMD`, `DSS.RFBI_PARAM`, `DSS.RFBI_DATA`, `DSS.RFBI_READ`, and `DSS.RFBI_STATUS`). When the `DSS.RFBI_SYSSTATUS`[8] `BUSY` bit is set by hardware, any access to the registers is stalled, except for the `RFBI_DATA` register.

The `DSS.RFBI_SYSSTATUS`[9] `BUSYRFBIDATA` bit indicates whether there are still pending data in the interconnect FIFO associated with the register `RFBI_DATA` only.

- Command register  
Write a command at a time by writing in the `DSS.RFBI_CMD` register. If the previous command is not processed, the `DSS.RFBI_SYSSTATUS`[8] `BUSY` bit is set by hardware and the access to writing a new command is stalled.
- Parameter register  
Write a parameter at a time by writing in the `DSS.RFBI_PARAM` register.  
If the previous parameter is not processed, the `DSS.RFBI_SYSSTATUS`[8] `BUSY` bit is set by hardware and the access to writing a new parameter is stalled.
- Data register  
Write one or two pixels at a time by writing in the `RFBI_DATA` register (when `DSS.RFBI_CONFIG`<sub>*i*</sub>[10:9] `CYCLEFORMAT` = 0x3 with *i* = 0, 1, two pixels must be written contiguously, no other access to RFBI registers except `DSS.RFBI_DATA` is allowed).  
The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the `DSS.RFBI_CONFIG`<sub>*i*</sub>[8:7] `L4FORMAT` bit field indicates the number of pixels for each L4 access to the register and the order of the pixels  
If the previous data are not processed, the `DSS.RFBI_SYSSTATUS`[8] `BUSY` bit is set by hardware and any access for writing new data is stalled. When the `DSS.RFBI_SYSSTATUS`[8] `BUSY` bit is reset by hardware, the access is not stalled.

- Read/status register  
Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI\_READ or DSS.RFBI\_STATUS registers. In this case, the DSS.RFBI\_SYSSTATUS[8] BUSY bit is set until the data are available in the register.  
When the DSS.RFBI\_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI\_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

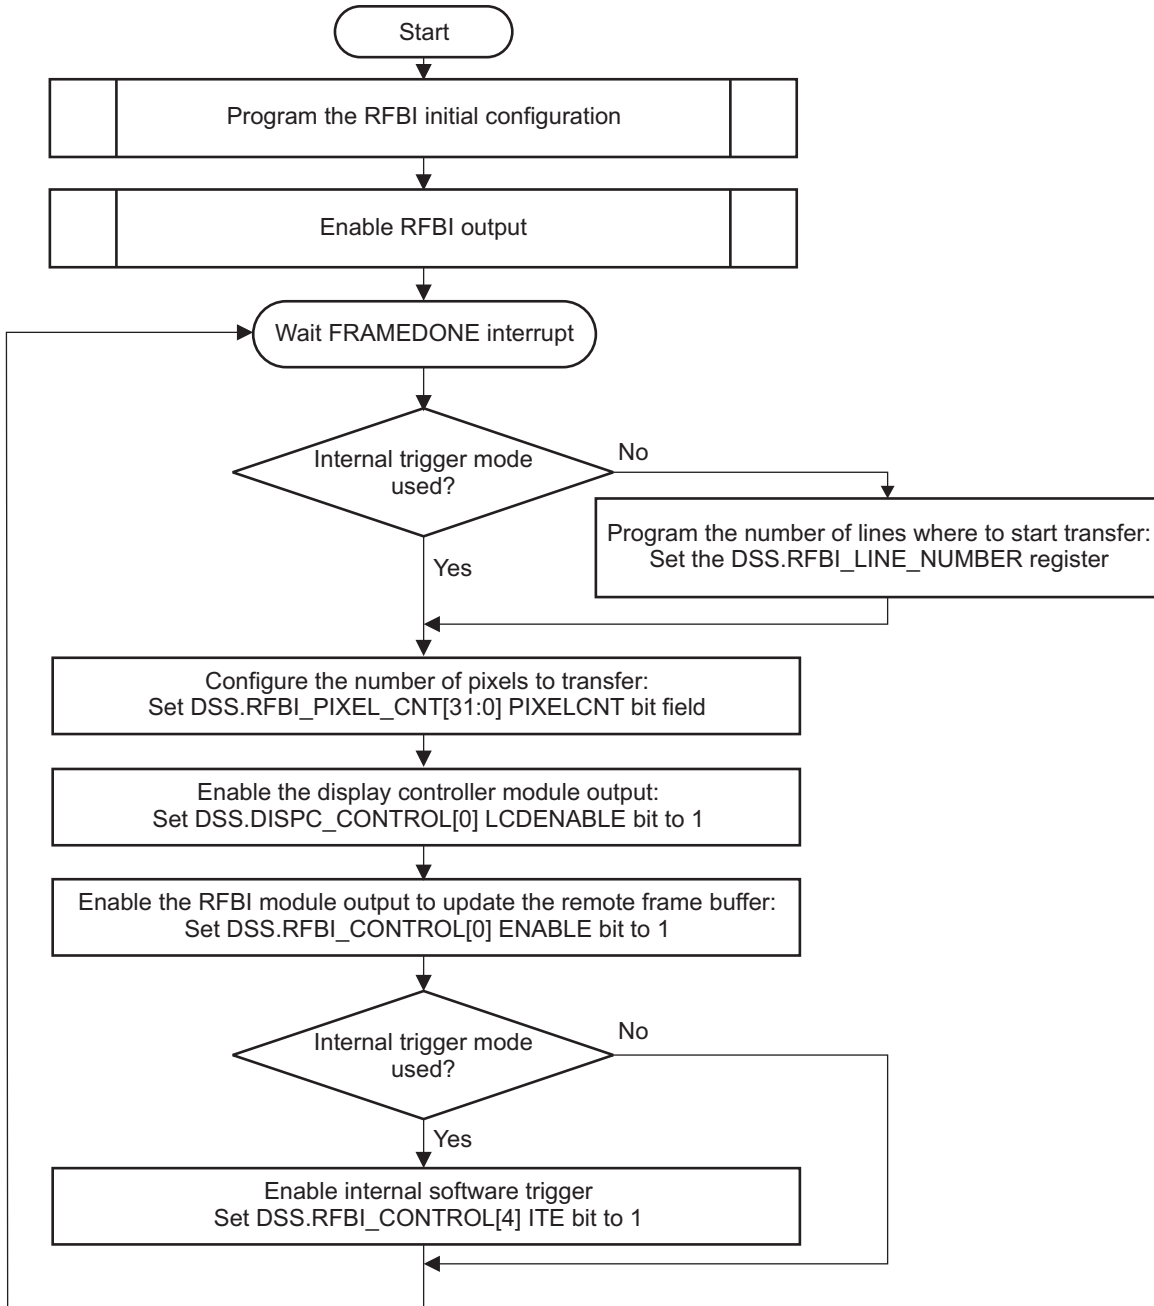

#### 15.5.7.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE bit field to 0x0
- External trigger mode:
  - TE external trigger mode when setting the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE bit field to 0x1
  - HSYNC/VSYNC external trigger mode when setting the DSS.RFBI\_CONFIGi[3:2] TRIGGERMODE bit field to 0x2

Figure 15-145 gives an example of how to program and use the RFBI module:

Figure 15-145. How to Use RFBI

dss-192

Figure 15-146 details how to configure the RFBI registers:

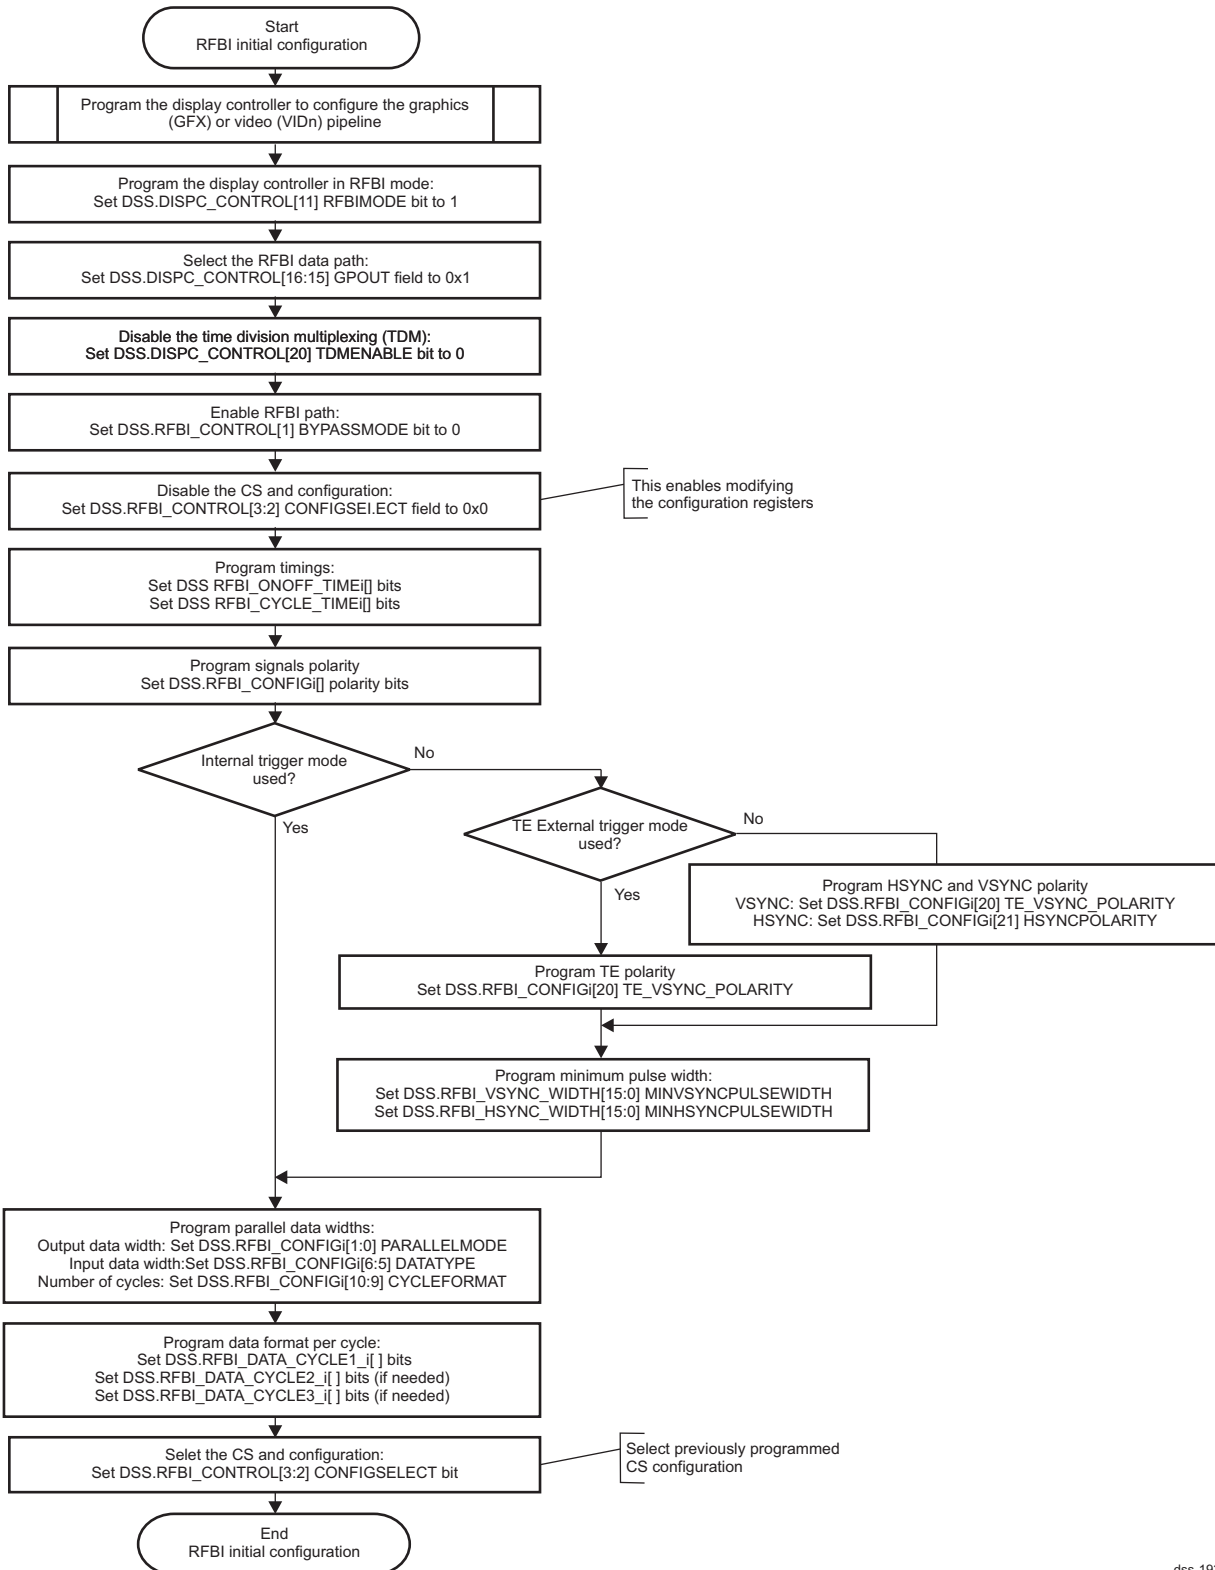

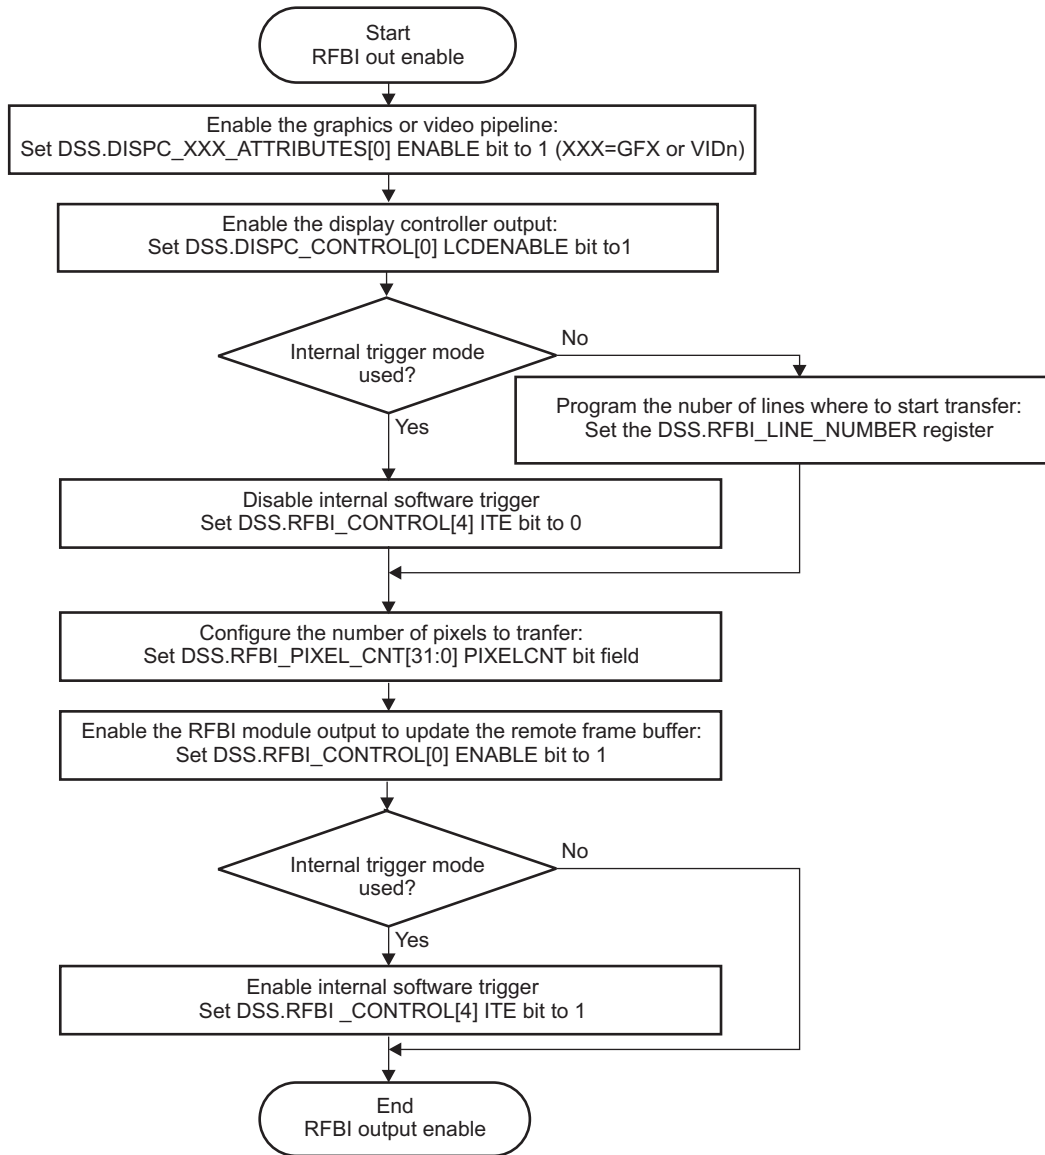

**Figure 15-146. RFBI Initial Configuration**

Figure 15-147 describes how to enable the RFBI module.

Figure 15-147. RFBI Output Enable

dss-324

## 15.5.8 Video Encoder Basic Programming Model

### 15.5.8.1 Video Encoder Software Reset

By setting the DSS.VENC\_F\_CONTROL[8] RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

---

**Note:** Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

---

### 15.5.8.2 Video DAC Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or
- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2 (chroma analog signal)

Selection is performed with DSS.DSS\_CONTROL[6] VENC\_OUT\_SEL bit:

- When VENC\_OUT\_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
- When VENC\_OUT\_SEL bit is set to 1, video DAC1 is selected for luma signal

One of the first VENC settings is to enable the output of the video DACs. This setting depends on the video output format:

- CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC\_OUTPUT\_CONTROL[1] COMPOSITE\_ENABLE bit to 1
- Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC\_OUTPUT\_CONTROL[0] LUMA\_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC\_OUTPUT\_CONTROL[2] CHROMA\_ENABLE bit to 1

### 15.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC\_F\_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC\_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC\_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in [Table 15-69](#), depending on the video standard used (PAL or NTSC). The DSS.VENC\_F\_CONTROL and DSS.VENC\_SYNC\_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC\_CONTROL[6] GODIGITAL bit and the DSS.DISPC\_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC\_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC\_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

### 15.5.8.4 Video Encoder Register Settings

For video encoder programming, see [Table 15-69](#). This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

**Table 15-69. Video Encoder Register Programming Values**

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000
VENC_VIDOUT_CTRL	0x00000001	0x00000001

VENC_OUTPUT_TEST	0x00000000	0x00000000

**Note:** The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC\_SIZE\_DIG[10:0] PPL = 720 - 1 = 719 = 0x2CF

DSS.DISPC\_SIZE\_DIG[26:16] LPP = (482/2) - 1 = 240 = 0xF0

DSS.DISPC\_GFX\_BA0 or DSS.DISPC\_VIDn\_BA0 = Base address of even bit field data

DSS.DISPC\_GFX\_BA1 or DSS.DISPC\_VIDn\_BA1 = Base address of odd bit field data

### 15.5.9 SDI Basic Programming Model

This section describes how to configure the SDI module for FlatLink3G-compliant LCD panel support.

Configure the SDI, and then configure the display controller.

### 15.5.9.1 SDI Configuration

**Note:** To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC\_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode)
- Set the DSS.DISPC\_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS\_SDI\_CONTROL[1:0] SDI\_BWSEL bit field to 0x2 (color depth is 24 bits)

#### 15.5.9.1.1 SDI PLL Configuration

The programming of the PLL divisor must be consistent with the choice of the number of data pairs. The PLL divisor determines the multiplication factor from the pixel clock frequency to data rate.

Table 15-70 lists some example values of the PLL settings for TI FlatLink3G.

**Table 15-70. PLL Divisor Example Values for TI FlatLink3G**

		24-BPP data		
		1 data pair	2 data pairs	3 data pairs
Recommended values	Pixel clock frequency (MHz)	15	30	65
	DSS.DSS_PLL_CONTROL[16:11]			
	SDI_PLL_REGN bit field (N factor = SDI_PLL_REGN bit field value + 1)	0x7	0xE	0xF
	DSS.DSS_PLL_CONTROL[10:1]			
	SDI_PLL_REGM bit field (M factor)	0xF0	0xE1	0x140
	DDS.DSS_PLL_CONTROL[19]			
	SDI_PLL_HIGHFREQ	0	0	1
Effective PLL divisor value (M/N)	30	15	10	

For more details on SDI PLL programming settings, see [Section 15.6.3](#).

#### 15.5.9.1.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC\_POL\_FREQ[16] RF bit to drive HSYNC and VSYNC on the rising edge of PCLK.
  - Set the DSS.DISPC\_POL\_FREQ[17] ONOFF bit.
  - Clear the DSS.DISPC\_POL\_FREQ[14] IPC bit to drive the pixel data on the rising edge of PCLK.
  - Set the DSS.DISPC\_CONTROL[29] LCDENABLEPOL bit to set the LCD-enable signal active high.
- The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:
- Set the DSS.DISPC\_POL\_FREQ[13] IHS bit to 1 to set HSYNC active low.
  - Set the DSS.DISPC\_POL\_FREQ[12] IVS bit to 1 to set VSYNC active low.
  - Clear the DSS.DISPC\_POL\_FREQ[15] IEO bit to set the data enable active high.

#### 15.5.9.1.3 Number of Data Pairs

To select the number of data pairs used to transmit display data between the device and the display panel, set the DSS.DSS\_SDI\_CONTROL[3:2] SDI\_PRSEL field.

Table 15-71 lists the different values for these bits based on the number of data pairs.

**Table 15-71. SDI Pixel Data Format**

	<b>DSS.DSS_SD<sub>I</sub>_CONTROL[3:2] SDI_PRSEL</b>
1 data pair (DATA1 pair)	00
2 data pairs (DATA1 and DATA2 pair)	01
3 data pairs (DATA1, DATA2, and DATA3 pair)	10

### 15.5.9.2 SDI Power-Management Programming Sequence

This section describes the software sequence for powering on and powering down the SDI module.

#### 15.5.9.2.1 SDI Reset State

After DSS power domain reset or power-on reset, the SDI module is in low-power mode by default with the following configuration:

- Display SS pads multiplexing is in parallel mode and not in SDI mode:
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[18:16]MUXMODE1 field values is 0x0: SDI\_DATA1N/SDI\_DATA1P signals are not mapped on dss\_data10/dss\_data11 pins.
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[18:16]MUXMODE1 bit field values is 0x0: SDI\_DATA2N/SDI\_DATA2P signals are not mapped on dss\_data12/dss\_data13 pins.
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[18:16]MUXMODE1 bit field values is 0x0: SDI\_DATA3N/SDI\_DATA3P signals are not mapped on dss\_data14/dss\_data15 pins.
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[18:16]MUXMODE1 bit field values is 0x0: SDI\_VSYNC/SDI\_HSYNC signals are not mapped on dss\_data18/dss\_data19 pins.
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[18:16]MUXMODE1 bit field values is 0x0: SDI\_DEN/SDI\_STP signals are not mapped on dss\_data20/dss\_data21 pins.
  - CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[2:0]MUXMODE0 and CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[18:16]MUXMODE1 bit field values is 0x0: SDI\_CLKP/SDI\_CLKN signals are not mapped on dss\_data22/dss\_data23 pins.
- SDI PLL is in reset mode: the DSS.DSS\_PLL\_CONTROL[18]SDI\_PLL\_SYSRESET bit value is 0x0.

#### 15.5.9.2.2 SDI Power On Sequence

When exiting OFF mode, to power-on the SDI module, software users must program the following sequence:

1. Program the SDI pads multiplexing configuration:
  - a. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[2:0]MUXMODE0 bit field to 0x1 to select SDI\_DATA1N signal on dss\_data10 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[18:16]MUXMODE1 bit field to 0x1 to select SDI\_DATA1P signal on dss\_data11 pin.
  - b. For 2-data and 3-data pair mode: set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[2:0]MUXMODE0 bit field to 0x1 to select SDI\_DATA2N on dss\_data12 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[18:16]MUXMODE1 bit field to 0x1 to select SDI\_DATA2P signal on dss\_data13 pin.
  - c. For 3-data pair mode: set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[2:0]MUXMODE0 bit field to 0x1 to select SDI\_DATA3N on dss\_data14 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[18:16]MUXMODE1 bit field to 0x1 to select SDI\_DATA3P signal on dss\_data15 pin.

- d. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[2:0]MUXMODE0 bit field to 0x1 to select SDI\_VSYNC signal on dss\_data18 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[18:16]MUXMODE1 bit field to 0x1 to select SDI\_HSYNC signal on dss\_data19 pin.
  - e. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[2:0]MUXMODE0 bit field to 0x1 to select SDI\_DEN signal on dss\_data20 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[18:16]MUXMODE1 bit field to 0x1 to select SDI\_STP signal on dss\_data21 pin.
  - f. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[2:0]MUXMODE0 bit field to 0x1 to select SDI\_CLKP signal on dss\_data22 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[18:16]MUXMODE1 bit field to 0x1 to select SDI\_CLKN signal on dss\_data23 pin.
2. Wait 1 ms.
  3. Release the SDI PLL reset signal by setting the DSS.DSS\_PLL\_CONTROL[18]SDI\_PLL\_SYSRESET bit to 0x1.

---

**Note:** The same software sequence is needed when the DSS power domain is set to ON.

---

### 15.5.9.2.3 SDI Power-Down Sequence

To power down the SDI module, software users must program the following sequence:

1. Power down the SDI PLL by setting the DSS.DSS\_PLL\_CONTROL[18]SDI\_PLL\_SYSRESET bit to 0x0.
2. Power-down the SDI pads:
  - a. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[2:0]MUXMODE0 bit field to 0x0 to un-select SDI\_DATA1N signal on dss\_data10 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA10[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_DATA1P signal on dss\_data11 pin.
  - b. For 2-data and 3-data pair mode: set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[2:0]MUXMODE0 bit field to 0x0 to un-select SDI\_DATA2N on dss\_data12 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA12[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_DATA2P signal on dss\_data13 pin.
  - c. For 3-data pair mode: set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[2:0]MUXMODE0 bit field to 0x0 to un-select SDI\_DATA3N on dss\_data14 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA14[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_DATA3P signal on dss\_data15 pin.
  - d. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[2:0]MUXMODE0 bit field to 0x0 to un-select SDI\_VSYNC signal on dss\_data18 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA18[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_HSYNC signal on dss\_data19 pin.
  - e. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[2:0]MUXMODE0 field to 0x0 to un-select SDI\_DEN signal on dss\_data20 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA20[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_STP signal on dss\_data21 pin.
  - f. Set the CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[2:0]MUXMODE0 bit field to 0x0 to un-select SDI\_CLKP signal on dss\_data22 pin and CONTROL.CONTROL\_PADCONF\_DSS\_DATA22[18:16]MUXMODE1 bit field to 0x0 to un-select SDI\_CLKN signal on dss\_data23 pin.

---

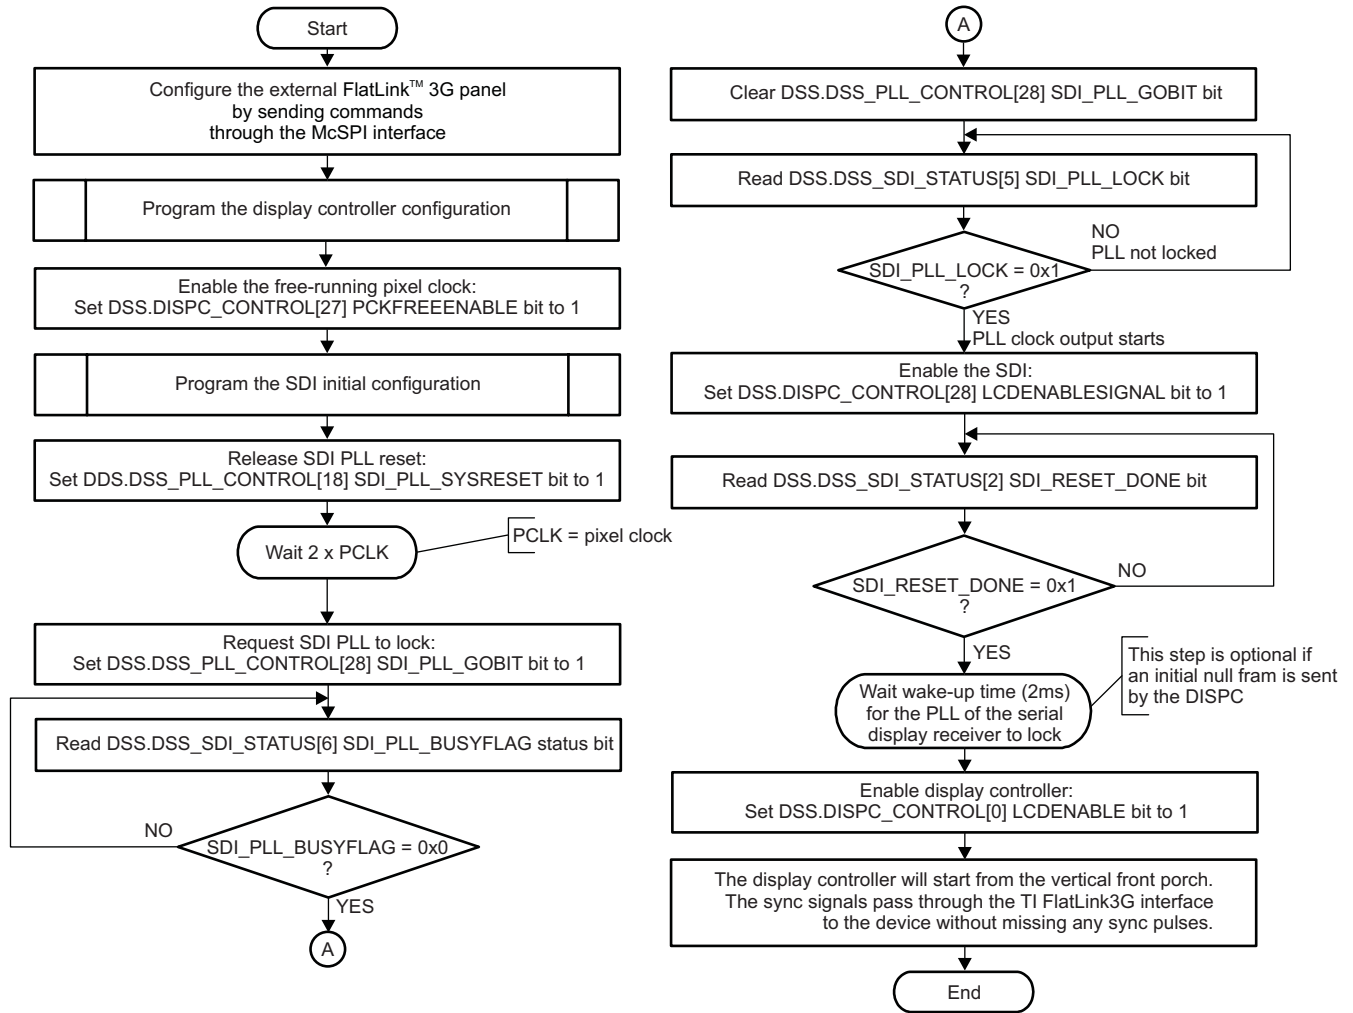

**Note:** The same software sequence is needed to shut-down the DSS power domain.

---

15.5.9.3 SDI Start Sequence

Figure 15-148 describes the SDI start sequence.

Figure 15-148. SDI Start Sequence

dss-108

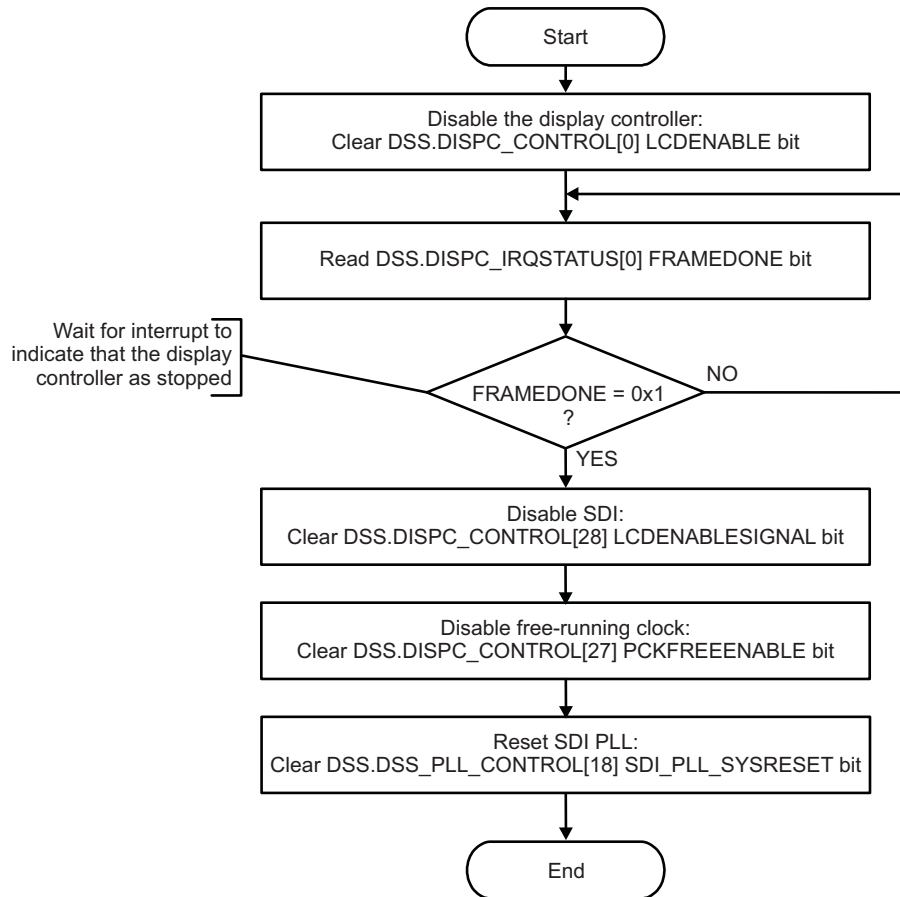

**Note:** The lock status of the SDI PLL is connected to the GPIO\_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see [Chapter 25, General-Purpose Interface](#).

**Note:** TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at [www.ti.com](http://www.ti.com).

### 15.5.9.4 SDI Stop Sequence

Figure 15-149 describes the SDI stop sequence.

**Figure 15-149. SDI Stop Sequence**

dss-110

### 15.5.9.5 Clock Source/Frequency Change Sequence

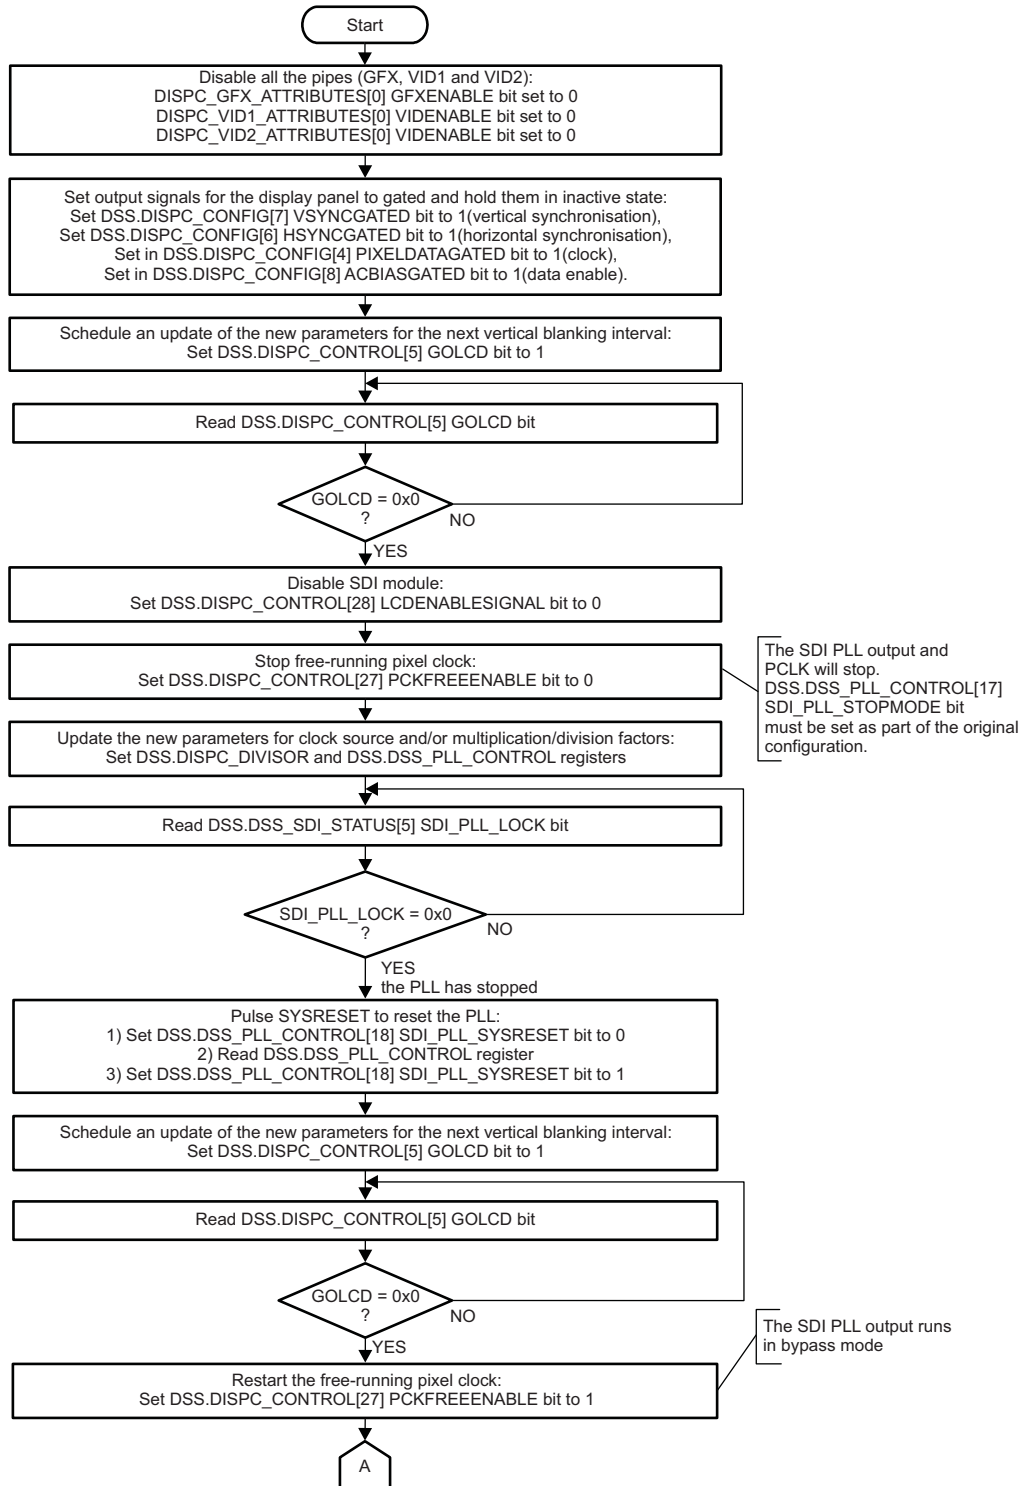

To change clock source or frequency, the simplest procedure is to follow the stop and start sequences documented above. If it is desired to change these without stopping the display a more rigorous procedure must be used as follows. The intent of this procedure is to perform the changes as quickly as possible during the vertical blanking interval and hence to minimize any visible display effect due to the increased blanking time.

15.5.9.5.1 Complete Sequence

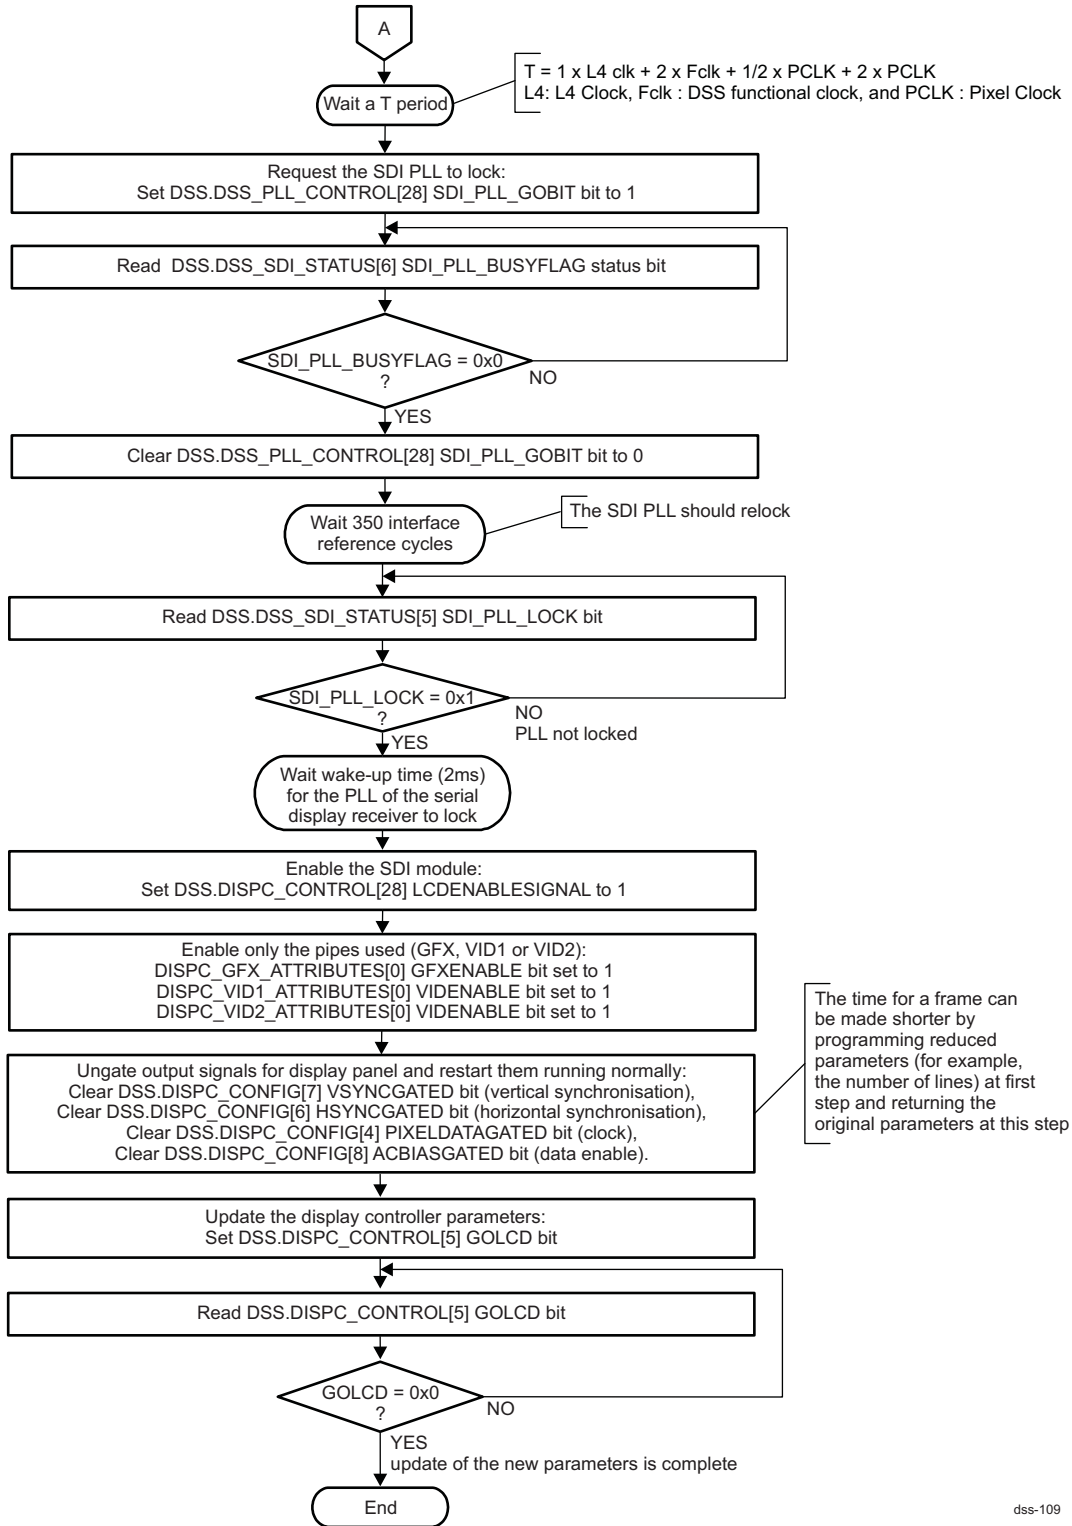

Figure 15-150 and Figure 15-151 describe the clock source and frequency change sequence of the SDI.

Figure 15-150. SDI Clock Source/Frequency Change Sequence Part A

dss-111

**Figure 15-151. SDI Clock Source/Frequency Change Sequence Part B**

dss-109

**Note:** One interface reference cycle is defined as follows:

Pixel Clock Frequency (PCLK)/SDI\_PLL\_REGN[5:0]/SDI\_PLL\_HIGHFREQ

Assuming the DSS.DSS\_PLL\_CONTROL[25:22] SDI\_PLL\_FREQSEL bit field value is between 0xB and 0xF and the DSS.DSS\_PLL\_CONTROL[27:26] SDI\_PLL\_LOCKSEL bit field is set to 0x0.

**Note:** The lock status of the SDI PLL is connected to the GPIO\_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see [Chapter 25, General-Purpose Interface](#).

**Note:** TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at [www.ti.com](http://www.ti.com).

#### **15.5.9.5.2 Simplified Sequence When LCD and PCD Are Swapped**

If the values in the DSS.DISPC\_DIVISOR[23:16] LCD and DSS.DISPC\_DIVISOR[7:0] PCD are exchanged (for example to reduce the internal display controller functional clock frequency while keeping the pixel clock frequency unchanged) with no other changes in the clock path, then there will be no discontinuity in the pixel clock. As a consequence the change will be transparent to the SDI module.

#### **15.5.9.6 SDI Error Management**

The DSS.DSS\_SDI\_STATUS[3] SDI\_ERROR status bit indicates an internal buffer underflow/overflow. If such an error occurs, the SDI module must be disabled and enabled again to realign the buffer. This is done by setting the DSS.DISPC\_CONTROL[28] LCDENABLESIGNAL bit to 0 (disabling) and to 1 (enabling). Ensure that the DSS.DSS\_SDI\_STATUS[2] SDI\_RESET\_DONE bit is set to 1. If this SDI error occurs during the debug phase, it is often due to programming incompatible values for MDIV, NDIV, and PDIV parameters for SDI PLL settings.

The SDI\_ERROR internal signal is connected to the GPIO\_82 internal signal of the GPIO3 module. Using the GPIO\_82 signal, the GPIO3 bank generates two interrupts (GPIO3\_MPU\_IRQ and GPIO3\_IVA2\_IRQ) to alert the MPU or IVA2.2 subsystems, respectively, about any SDI error. For additional information, see [Chapter 25, General-Purpose Interface](#).

## 15.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the display subsystem.

### 15.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously.

#### 15.6.1.1 Filtering

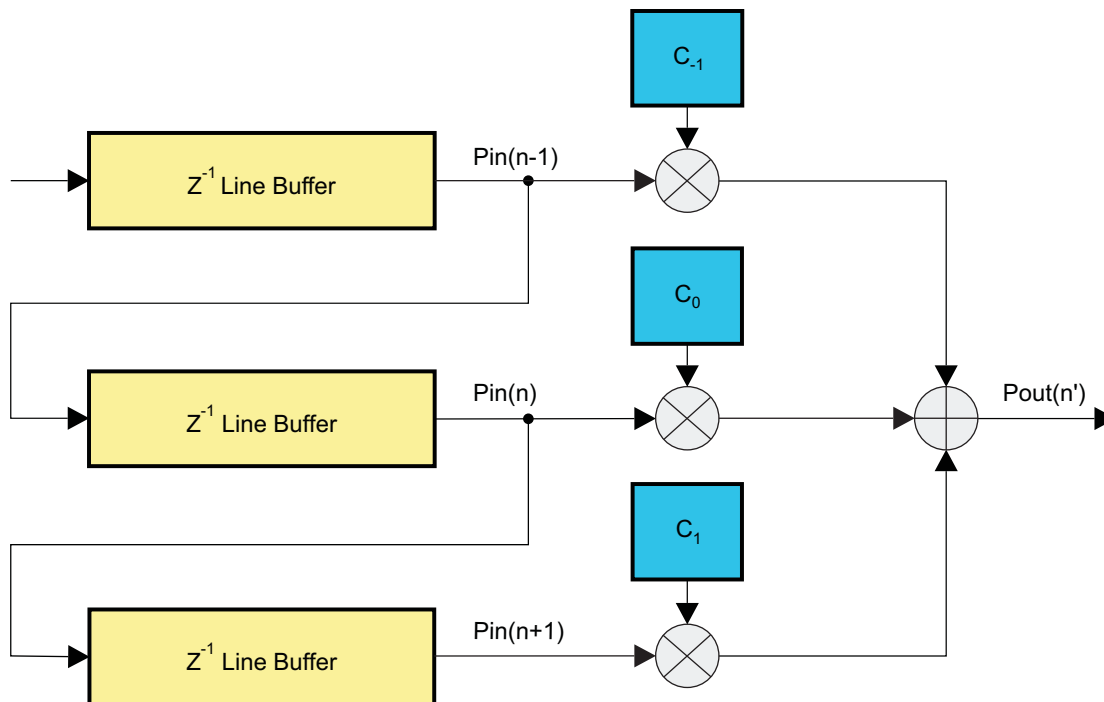

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

##### 15.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable.

The vertical 3-tap filtering macro architecture is shown in [Figure 15-152](#).

**Figure 15-152. Vertical Filtering Macro Architecture (Three Taps)**

dss-112

For the 3-tap vertical up-/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left( \sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E067

(15-8)

Legend:

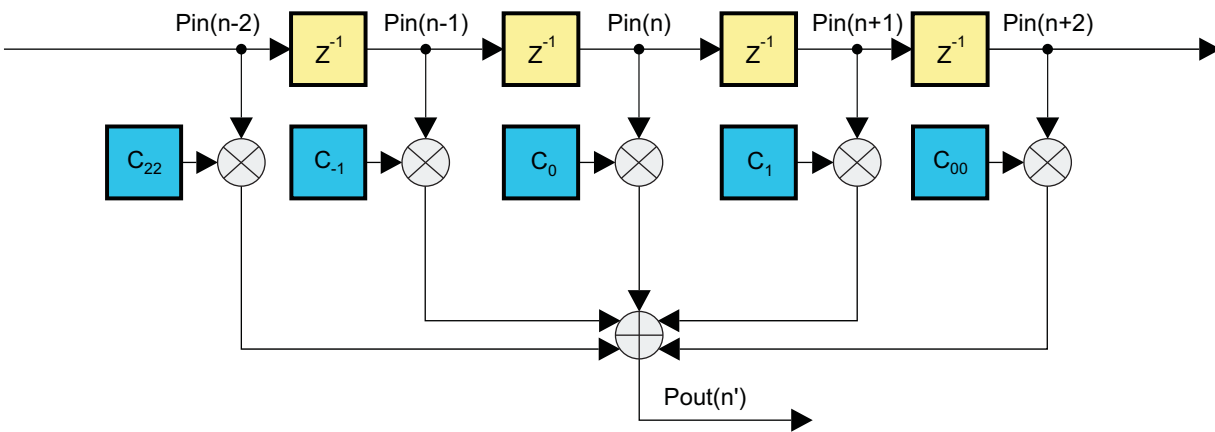

- Rout: R component output
- C<sub>i</sub>( ): Vertical FIR coefficients
- Rin: R component input
- The line (n+1) is older than line (n).

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C<sub>0</sub>( ), which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in Figure 15-153.

**Figure 15-153. Vertical Filtering Macro Architecture (Five Taps)**

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times Rin(n+i) \right) \gg 7 \tag{15-9}$$

dss-E066

Legend:

- Rout: R component output
- C<sub>i</sub>( ): Vertical FIR coefficients with C<sub>+2</sub>( )=C<sub>00</sub>( ) and C<sub>-2</sub>( )=C<sub>22</sub>( )
- Rin: R component input
- The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C<sub>0</sub>( ), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

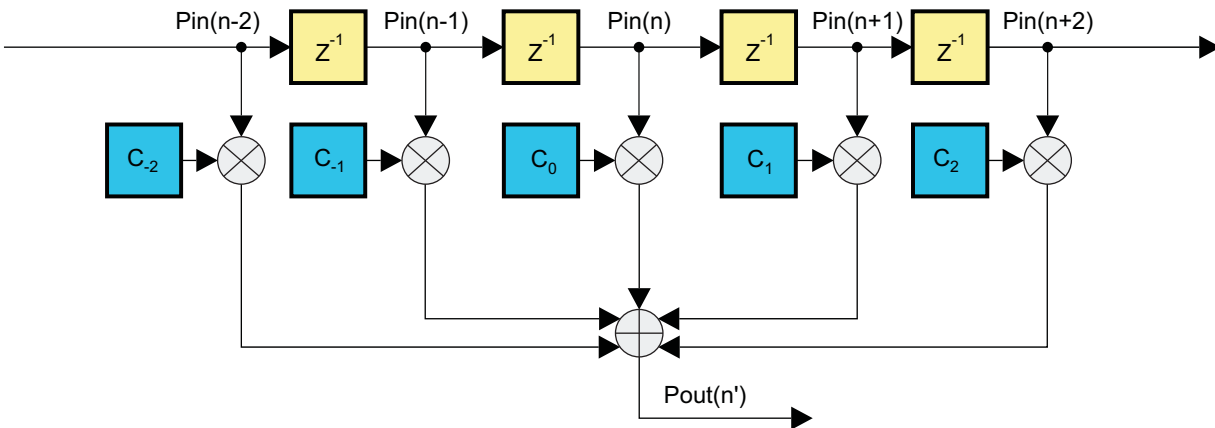

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

### 15.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 15-154](#).

**Figure 15-154. Horizontal Filtering Macro Architecture (Five Taps)**

dss-114

For the 5-tap horizontal up-/downsampling, the equation is (with the example of R component):

$$R_{out}(n) = \left( \sum_{i=-3}^{i=3} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E115

(15-10)

Legend:

Rout: R component output

$C_i()$ : Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient  $C_0()$ , which is unsigned).

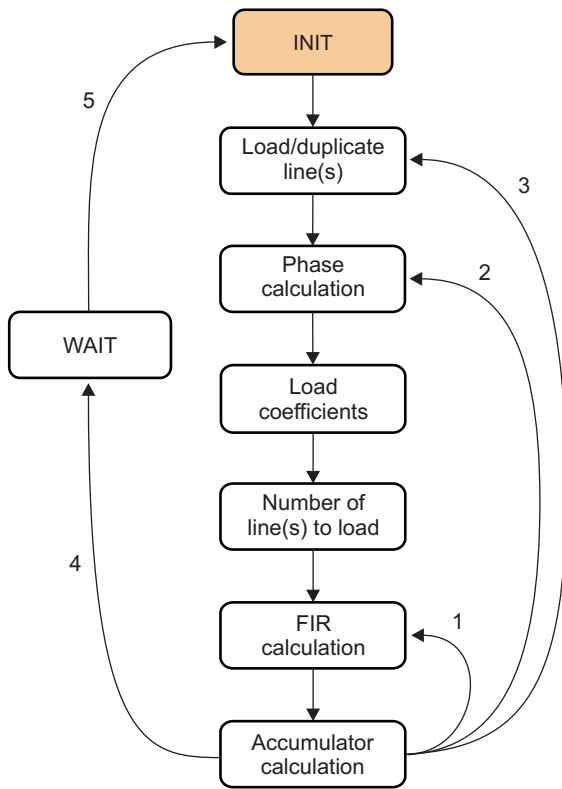

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

### 15.6.1.2 Scaling Algorithms

The up-/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 15-155](#) presents the vertical up-/downsampling FSM.

Figure 15-155. Vertical Up-/Down-Sampling Algorithm

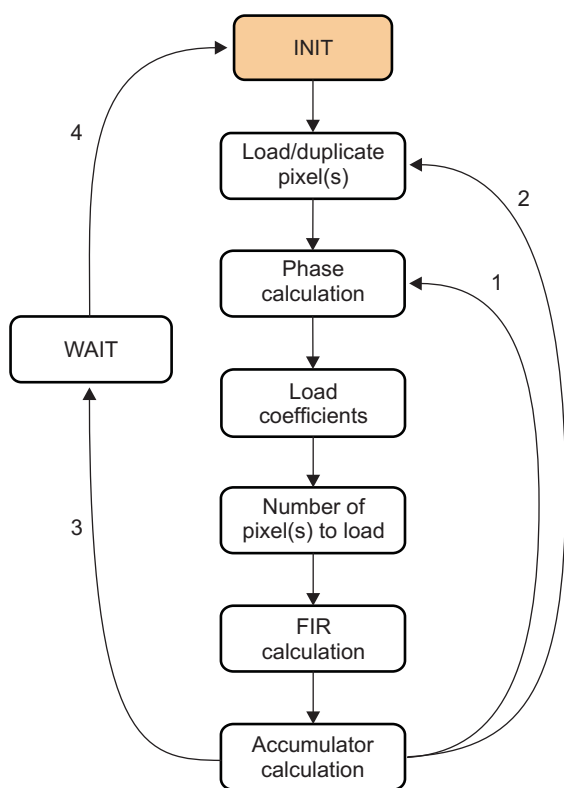

- 1: New pixel on the same line
- 2: New pixel on following line (no line to load)
- 3: New pixel on following line (line[s] to load)
- 4: End of frame
- 5: Restart of a new frame

INIT	Initialisation of buffer with duplication, accu value reset with register value based on the field polarity if present
Phase calculation	Phase = accu[9:7]
Number of line(s) to load	Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
FIR calculation	$R_{out}(n) = \left( \sum_{i=-p}^{i=p} C_i(\phi) * R_{in}(n + i) \right) >> 7$
Accumulator calculation	Accu = accu + inc

dss-116

Figure 15-156 presents the horizontal up-/downsampling FSM.

**Figure 15-156. Horizontal Up-/Down-Sampling Algorithm**

- 1: New pixel (no pixel to load)
- 2: New pixel (pixel(s) to load)
- 3: End of line
- 4: Restart of a line

- INIT** Initialization of buffer with duplication, accu value reset with register value based on the field polarity if present
- Phase calculation** Phase = accu[9:7]
- Number of line(s) to load** Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
- FIR calculation**  $R_{out}(n) = \left( \sum_{i=-p}^{i=p} C_i(\phi) * R_{in}(n + i) \right) >> 7$
- Accumulator calculation** Accu = accu + inc

dss-117

### 15.6.1.3 Scaling Settings

**Notes:**

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

#### 15.6.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC\_VIDn\_BAj
- DSS.DISPC\_VIDn\_ATTRIBUTES
- DSS.DISPC\_VIDn\_FIR
- DSS.DISPC\_VIDn\_ACCUI
- DSS.DISPC\_VIDn\_FIR\_COEF\_Hi
- DSS.DISPC\_VIDn\_FIR\_COEF\_HVi
- DSS.DISPC\_VIDn\_FIR\_COEF\_Vi

Table 15-72 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

**Table 15-72. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)**

C <sub>x</sub> ()	VidFIRVC <sub>x</sub> ()
C <sub>-1</sub> ()	VidFIRVC <sub>2</sub> ()

**Table 15-72. Vertical FIR Coefficients  
Corresponding Table (3-Tap Configuration)  
(continued)**

$C_x()$	VidFIRVC $_x()$
$C_0()$	VidFIRVC $_1()$
$C_1()$	VidFIRVC $_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- VidFIRVC $_2()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[31:24] VIDFIRVC2
- VidFIRVC $_1()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[23:16] VIDFIRVC1
- VidFIRVC $_0()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[15:8] VIDFIRVC0

Table 15-73 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

**Table 15-73. Vertical FIR Coefficients Corresponding  
Table (5-Tap Configuration)**

$C_x()$	VidFIRVC $_x()$
$C_{22}()$	VidFIRVC $_{22}()$
$C_{-1}()$	VidFIRVC $_2()$
$C_0()$	VidFIRVC $_1()$
$C_1()$	VidFIRVC $_0()$
$C_{00}()$	VidFIRVC $_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- VidFIRVC $_{22}()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Vi[15:8] VIDFIRVC22
- VidFIRVC $_2()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[31:24] VIDFIRVC2
- VidFIRVC $_1()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[23:16] VIDFIRVC1
- VidFIRVC $_0()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[15:8] VIDFIRVC0
- VidFIRVC $_{00}()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Vi[7:0] VIDFIRVC00

Table 15-74 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

**Table 15-74. Horizontal FIR Coefficients  
Corresponding Table (5-Tap Configuration)**

$C_x()$	VidFIRHC $_x()$
$C_{-2}()$	VidFIRHC $_4()$
$C_{-1}()$	VidFIRHC $_3()$
$C_0()$	VidFIRHC $_2()$
$C_1()$	VidFIRHC $_1()$
$C_2()$	VidFIRHC $_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- VidFIRHC $_4()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_HVi[7:0] VIDFIRHC4
- VidFIRHC $_3()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Hi[31:24] VIDFIRHC3
- VidFIRHC $_2()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Hi[23:16] VIDFIRHC2
- VidFIRHC $_1()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Hi[15:8] VIDFIRHC1
- VidFIRHC $_0()$  = DSS.DISPC\_VIDn\_FIR\_COEF\_Hi[7:0] VIDFIRHC0

### 15.6.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRIBUTES[0].VIDENABLE bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up-/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC\_VIDn\_ATTRIBUTES[6:5] VIDRESIZEENABLE bit field:

- When the VIDRESIZEENABLE[1] bit is set to 1, the video vertical up-/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the VIDRESIZEENABLE[0] bit is set to 1, the video horizontal up-/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the VIDRESIZEENABLE[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

---

**Notes:**

- Set a valid configuration before enabling the video up-/downsampling block.
  - Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 15.6.1.3.5](#) for more information concerning the filter coefficients.
- 

### 15.6.1.3.3 Factor

The following register bit fields define the increment value of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC\_VIDn\_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \quad \text{dss-E118} \quad (15-11)$$

---

**Notes:**

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
  - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
- 
- Horizontal up-/downsampling increment value (the DSS.DISPC\_VIDn\_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]} \quad \text{dss-E119} \quad (15-12)$$

---

**Notes:**

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
  - The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
- 

### 15.6.1.3.4 Initial Phase

- Vertical up-/downsampling accumulator value DSS.DISPC\_VIDn\_ACCU[25:16] VIDVERTICALACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.

- Vertical up-/downsampling accumulator value DSS.DISPC\_VIDn\_ACCU[9:0] VIDHORIZONTALACCU

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 15-75 lists the vertical/horizontal accumulator values and phases

**Table 15-75. Vertical/Horizontal Accumulator Phase**

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

**Note:** For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

#### 15.6.1.3.5 Coefficients

- **Vertical up-/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_HVi and DSS.DISPC\_VIDn\_FIR\_COEF\_V)**

The 3-tap vertical up-/downsampling coefficients are defined in DSS.DISPC\_VIDn\_FIR\_COEF\_HVi registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ( $C_{22}()$  and  $C_{00}()$ ).

In case of 5-tap configuration, both sets of registers, DSS.DISPC\_VIDn\_FIR\_COEF\_HVi and DSS.DISPC\_VIDn\_FIR\_COEF\_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC\_VIDn\_FIR\_COEF\_HV, is used.

- **Horizontal up-/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_Hi and DSS.DISPC\_VIDn\_FIR\_COEF\_HV)**

The 5-tap horizontal up-/downsampling coefficients are defined in DSS.DISPC\_VIDn\_FIR\_COEF\_Hi and DSS.DISPC\_VIDn\_FIR\_COEF\_HVi registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up-/downsampling block.

Each DSS.DISPC\_VIDn\_FIR\_COEF\_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC\_VIDn\_FIR\_COEF\_HVi contains one 8-bit signed coefficient.

Table 15-76 through Table 15-81 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

##### 15.6.1.3.5.1 Up-Sampling

Table 15-76 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

**Table 15-76. Up-Sampling Vertical Filter Coefficients (Three Taps)**

Phases	VidFIRVC <sub>2</sub> ()	VidFIRVC <sub>1</sub> ()	VidFIRVC <sub>0</sub> ()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 15-77 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

**Table 15-77. Up-Sampling Vertical Filter Coefficients (Five Taps)**

Phases	VidFIRVC <sub>22</sub> ()	VidFIRVC <sub>2</sub> ()	VidFIRVC <sub>1</sub> ()	VidFIRVC <sub>0</sub> ()	VidFIRVC <sub>00</sub> ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 15-78 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

**Table 15-78. Up-Sampling Horizontal Filter Coefficients (Five Taps)**

Phases	VidFIRHC <sub>4</sub> ()	VidFIRHC <sub>3</sub> ( )	VidFIRHC <sub>2</sub> ()	VidFIRHC <sub>1</sub> ()	VidFIRHC <sub>0</sub> ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H1 = 0x0D7CF800
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV1 = 0x037B02FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H2 = 0x1E70F5FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV2 = 0x0C6F05FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H3 = 0x335FF5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV3 = 0x205907FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H4 = 0xF74949F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV4 = 0x00404000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H5 = 0xF55F33FB

- DSS.DISPC\_VIDn\_FIR\_COEF\_HV5 = 0x075920FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H6 = 0xF5701EFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV6 = 0x056F0CFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H7 = 0xF87C0DFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV7 = 0x027B0300

---

**Note:** In this case, the DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers are not used.

---

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_V0 = 0x00000000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H1 = 0x0D7CF800
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV1 = 0x0D7CF8FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_V1 = 0x0000FF00
- DSS.DISPC\_VIDn\_FIR\_COEF\_H2 = 0x1E70F5FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV2 = 0x1E70F5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V2 = 0x0000FEFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H3 = 0x335FF5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV3 = 0x335FF5FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_V3 = 0x0000FBFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H4 = 0xF74949F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV4 = 0xF7404000
- DSS.DISPC\_VIDn\_FIR\_COEF\_V04 = 0x000000F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_H5 = 0xF55F33FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV5 = 0xF55F33FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V5 = 0x0000FEFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H6 = 0xF5701EFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV6 = 0xF5701EFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_V6 = 0x0000FFFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H7 = 0xF87C0DFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV7 = 0xF87C0D00
- DSS.DISPC\_VIDn\_FIR\_COEF\_V7 = 0x000000FF

#### 15.6.1.3.5.2 Down-Sampling

Table 15-79 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

**Table 15-79. Down-Sampling Vertical Filter Coefficients (Three Taps)**

Phases	VidFIRVC <sub>2</sub> ()	VidFIRVC <sub>1</sub> ()	VidFIRVC <sub>0</sub> ()
0	36	56	36
1	40	57	31
2	45	56	27
3	50	55	23
4	18	55	55
5	23	55	50
6	27	56	45
7	31	57	40

Table 15-80 gives the 40 coefficients to program the vertical downsampling (5-tap configuration).

**Table 15-80. Down-Sampling Vertical Filter Coefficients (Five Taps)**

Phases	VidFIRVC <sub>22</sub> ()	VidFIRVC <sub>2</sub> ()	VidFIRVC <sub>1</sub> ()	VidFIRVC <sub>0</sub> ()	VidFIRVC <sub>00</sub> ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

Table 15-81 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

**Table 15-81. Down-Sampling Horizontal Filter Coefficients (Five Taps)**

Phases	VidFIRHC <sub>4</sub> ()	VidFIRHC <sub>3</sub> ( )	VidFIRHC <sub>2</sub> ()	VidFIRHC <sub>1</sub> ()	VidFIRHC <sub>0</sub> ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_H1 = 0x28371FFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV1 = 0x28391F04
- DSS.DISPC\_VIDn\_FIR\_COEF\_H2 = 0x2C361BFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV2 = 0x2D381B08
- DSS.DISPC\_VIDn\_FIR\_COEF\_H3 = 0x303516F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV3 = 0x3237170C
- DSS.DISPC\_VIDn\_FIR\_COEF\_H4 = 0x11343311
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV4 = 0x123737F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_H5 = 0x1635300C
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV5 = 0x173732F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_H6 = 0x1B362C08
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV6 = 0x1B382DFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H7 = 0x1F372804
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV7 = 0x1F3928FE

**Notes:**

- In this case, the DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers are not used.
- In this case, the downsampling factor must be higher than 1/2.

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_V0 = 0x00000000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H1 = 0x28371FFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV1 = 0x28371F04
- DSS.DISPC\_VIDn\_FIR\_COEF\_V1 = 0x000004FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H2 = 0x2C361BFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV2 = 0x2C361B08
- DSS.DISPC\_VIDn\_FIR\_COEF\_V2 = 0x000008FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H3 = 0x303516F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV3 = 0x3035160C
- DSS.DISPC\_VIDn\_FIR\_COEF\_V3 = 0x00000CF9
- DSS.DISPC\_VIDn\_FIR\_COEF\_H4 = 0x11343311
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV4 = 0x113433F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_V4 = 0x0000F711
- DSS.DISPC\_VIDn\_FIR\_COEF\_H5 = 0x1635300C
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV5 = 0x163530F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_V5 = 0x0000F90C
- DSS.DISPC\_VIDn\_FIR\_COEF\_H6 = 0x1B362C08
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV6 = 0x1B362CFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_V6 = 0x0000FB08
- DSS.DISPC\_VIDn\_FIR\_COEF\_H7 = 0x1F372804
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV7 = 0x1F3728FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V7 = 0x0000FE04

---

**Note:** This configuration must be used for vertical downsampling factors between 1/2 and 1/4

---

## 15.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On an OMAP platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings.

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

### 15.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.

- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

---

**Note:** In the device, the display subsystem has its own power domain (the DSS power domain).

---

## 15.6.2.2 Display Subsystem Clock

### 15.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1\_ALWON\_FCLK) and DSI PLL functional clock 1 (DSI1\_PLL\_FCLK):

- DSS1\_ALWON\_FCLK is sourced from DPLL4 (DPLL4\_ALWON\_FCLK), with several multipliers available and is configured in the PRM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field.
- DSI1\_PLL\_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1\_ALWON\_FCLK or DSI1\_PLL\_FCLK by configuring the DSS.DISPC\_CONTROL[0] DISPC\_CLK\_SWITCH bit

---

**Note:** When the DSI PLL is in bypass mode, the DSI1\_PLL\_FCLK clock is the DSS2\_ALWON\_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

---

The LCD logic clock is determined by the DSS.DISPC\_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS\_CONTROL register (either DSS1\_ALWON\_FCLK or DSS2\_ALWON\_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC\_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4\_ALWON\_FCLK) is enabled and running at 266 MHz:

The PRM.CM\_CLKSEL2\_PLL[18:8] PERIPH\_DPLL\_MULT bit field is set to 0x4 and the PRM.CM\_CLKSEL2\_PLL[6:0] PERIPH\_DPLL\_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

$$DPLL4\_ALWON\_FCLKOUTX2 = DPLL4\_ALWON\_FCLK(266MHz) \times 4/2 = 532 \text{ MHz}$$

---

**Note:** The DPLL4\_ALWON\_FCLKOUTX2 clock is an internal clock in DPLL4 module after the DPLL\_MULT and DPLL\_DIV stages. The DPLL4\_M4X2\_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1\_ALWON\_FCLK.

---

The DSS.DISPC\_CONTROL[0] DSS\_CLK\_SWITCH bit is set to 0x0 to select DSS1\_ALWON\_FCLK as the display subsystem functional clock:

$$DSS1\_ALWON\_FCLK = DPLL4\_M4X2\_CLK$$

The PRM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field is set to 0x08:

$$DSS1\_ALWON\_FCLK = \frac{DPLL4\_ALWON\_FCLKOUTX2(532MHz)}{8} = 66.5 \text{ MHz}$$

dss-E120

(15-13)

The DSS.DISPC\_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{\text{DSS1\_ALWON\_FCLK}(66.5\text{MHz})}{1} = 66.5 \text{ Mhz} \quad \text{dss-E121} \quad (15-14)$$

The DSS.DISPC\_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5\text{MHz})}{12} = 5.54 \text{ Mhz} \quad \text{dss-E122} \quad (15-15)$$

### 15.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

### 15.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC\_DIVISOR[7:0] PCD and DSS.DISPC\_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC\_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC\_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC\_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC\_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC\_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC\_DIVISOR[7:0] PCD to 0x4.

### 15.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 = 0x1
- PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 = 0x1
- PRCM.CM\_FCLKEN\_DSS[2] EN\_TV = 0x1
- PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS = 0x1
- PRCM.CM\_CLKEN\_PLL[18:16] EN\_PERIPH\_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

### 15.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1\_ALWON\_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1\_ALWON\_FCLK to DSI1\_PLL\_FCLK by setting the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit to 0x1.

---

**Note:** Before switching to DSI1\_PLL\_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

---

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM\_CLKEN\_PLL[18:16] EN\_PERIPH\_DPLL bit to 0x1.

- Automatically: When setting the PRCM.CM\_AUTOIDLE\_PLL[5:3] AUTO\_PERIPH\_DPLL bit field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96- MHz and 54- MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit to 0x0. The DSS1\_ALWON\_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1\_ALWON\_FCLK clock.

## 15.6.2.4 Autoidle and Smart Idle

### 15.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC\_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

### 15.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.DSS\_SYSCONFIG[4:3] SIDLEMODE
- Display controller: DSS.DISPC\_SYSCONFIG[4:3] SIDLEMODE
- RFBI: DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE

## 15.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC\_GFX\_FIFO\_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD
- DSS.DISPC\_GFX\_FIFO\_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO With the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

### 15.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.

- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

### 15.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. Figure 15-157 shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$f_{ps} = \frac{1}{[(Hsw + 1) + (Hrp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vrp + 320 + Vbp]} \times (PCLK)$$

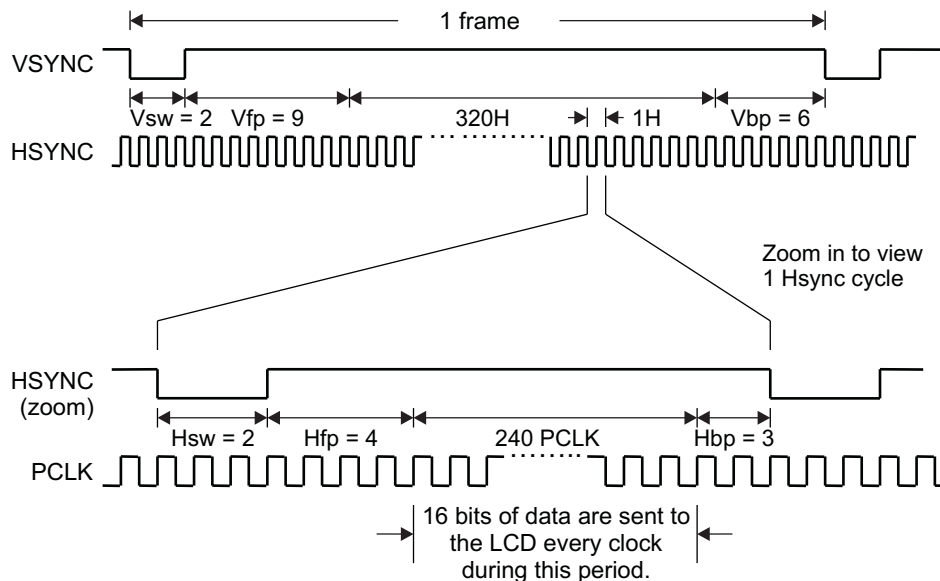

dss-E123 (15-16)

With:

- Hsw: DSS.DISPC\_TIMING\_H[7:0] HSW bit field value
- Hp: DSS.DISPC\_TIMING\_H[19:8] HFP bit field value
- Hbp: DSS.DISPC\_TIMING\_H[31:20] HBP bit field value
- Vsw: DSS.DISPC\_TIMING\_V[7:0] VSW bit field value
- Vp: DSS.DISPC\_TIMING\_V[19:8] VFP bit field value
- Vpb: DSS.DISPC\_TIMING\_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 15-157. QVGA LCD Timings

dss-124

The fps for the example of 6-MHz pixel clock with the setting shown in Figure 15-157 is as follows:

$$f_{ps} = \frac{1}{[(2 + 1) + 4 + 240 + 3] \times [(2 + 1) + 9 + 320 + 6]} \times 166.67 \times 10^{-9}$$

dss-E125 (15-17)

$$fps = 71Hz$$

### 15.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

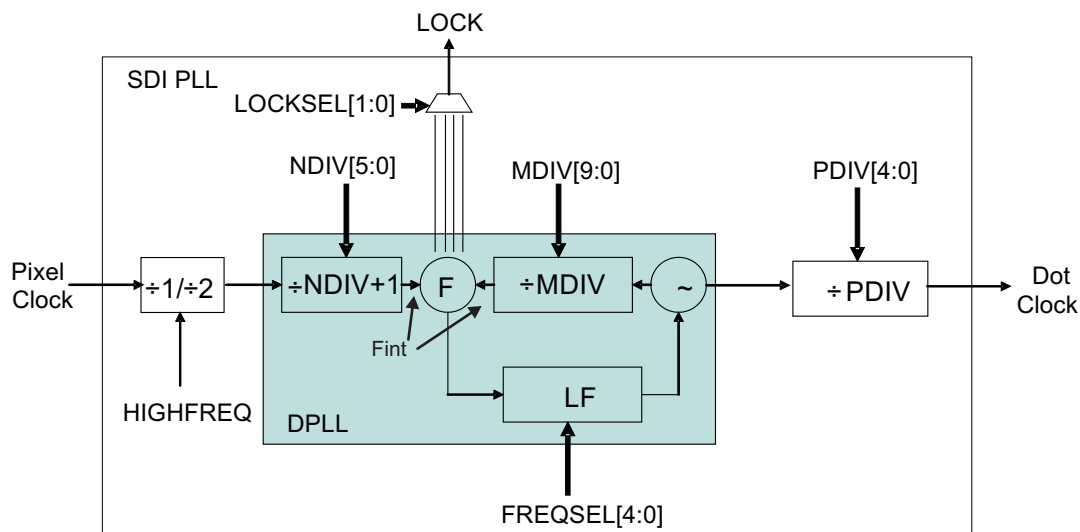

## 15.6.3 How to Configure the Serial Display Interface Module With FlatLink3G Protocol

This section describes the basic settings of Serial Display Interface (SDI) module and related Phase-Locked Loop (PLL).

### 15.6.3.1 SDI PLL Architecture

The SDI PLL architecture is based on the Digital Phase-Locked Loop (DPLL) that is described in [Chapter 4, Power, Reset, and Clock Management](#). [Figure 15-158](#) gives a functional description of the SDI PLL.

**Figure 15-158. SDI PLL Architecture**

dss-126

#### Notes:

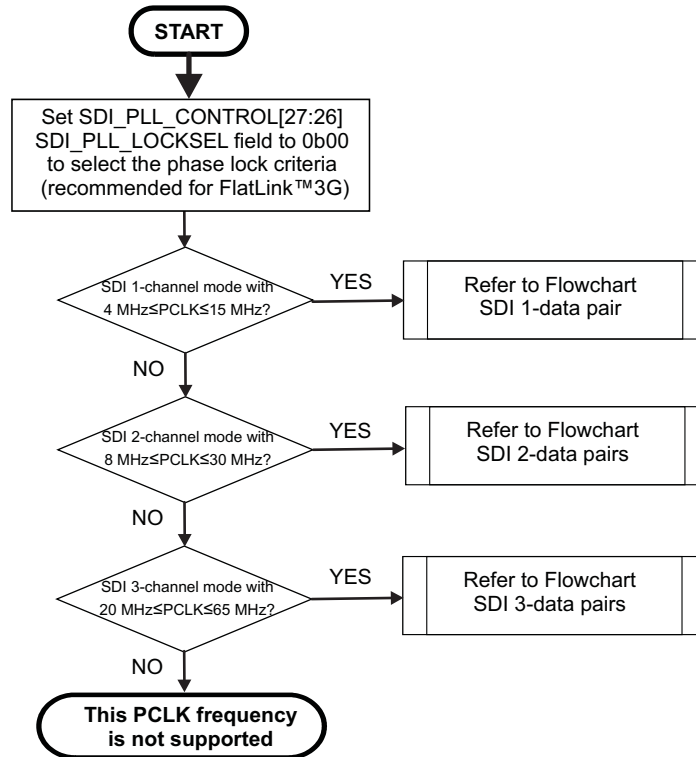

- FlatLink3G data rate is always at SCLK frequency.
- Software programmers must ensure that Pixel Clock = Dot Clock. If it is not the case the `DSS.DSS_SDI_STATUS[3]` SDI\_ERROR status bit will be set indicating the pixel buffer overflow/underflow.

### 15.6.3.2 SDI PLL Configuration

The SDI PLL configuration depends on the pixel clock (PCLK), and on the number of data pairs in the FlatLink 3G protocol.

The following flowcharts detail the SDI PLL configuration from the PCLK frequency point of view. [Figure 15-159](#) is the main flowchart. See [Figure 15-160](#), [Figure 15-161](#), and [Figure 15-162](#) for details in PLL setting depending the PCLK input frequency.

Figure 15-159. Main Flowchart

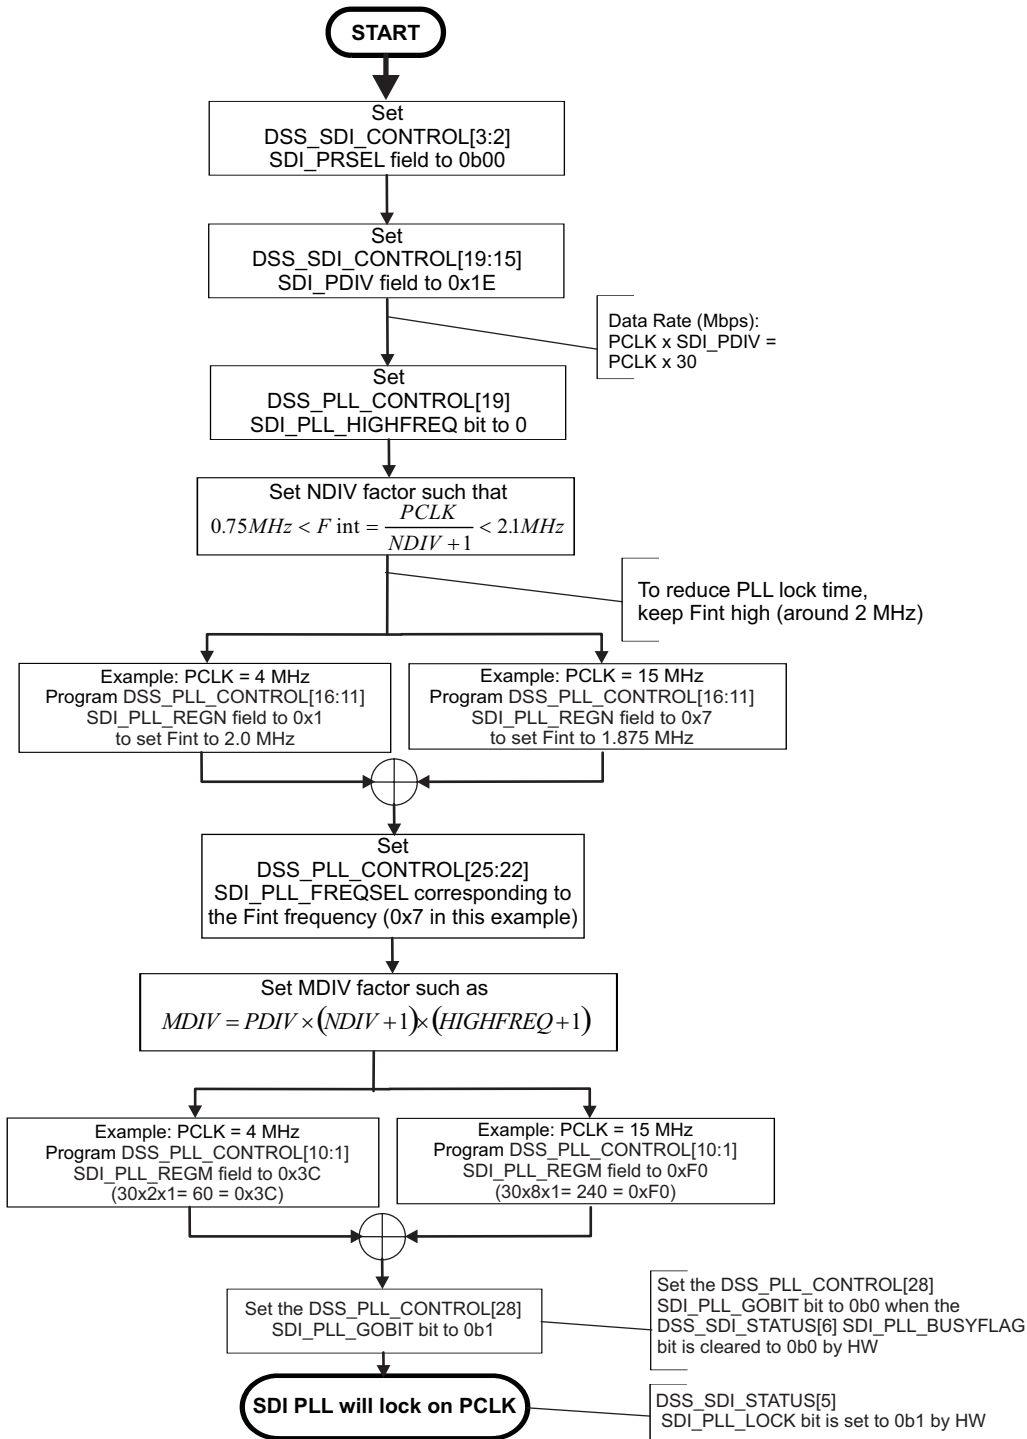

dss-127

---

**Note:** Compliance with the above ranges is required to meet the SN65LVDS302 receiver specifications.

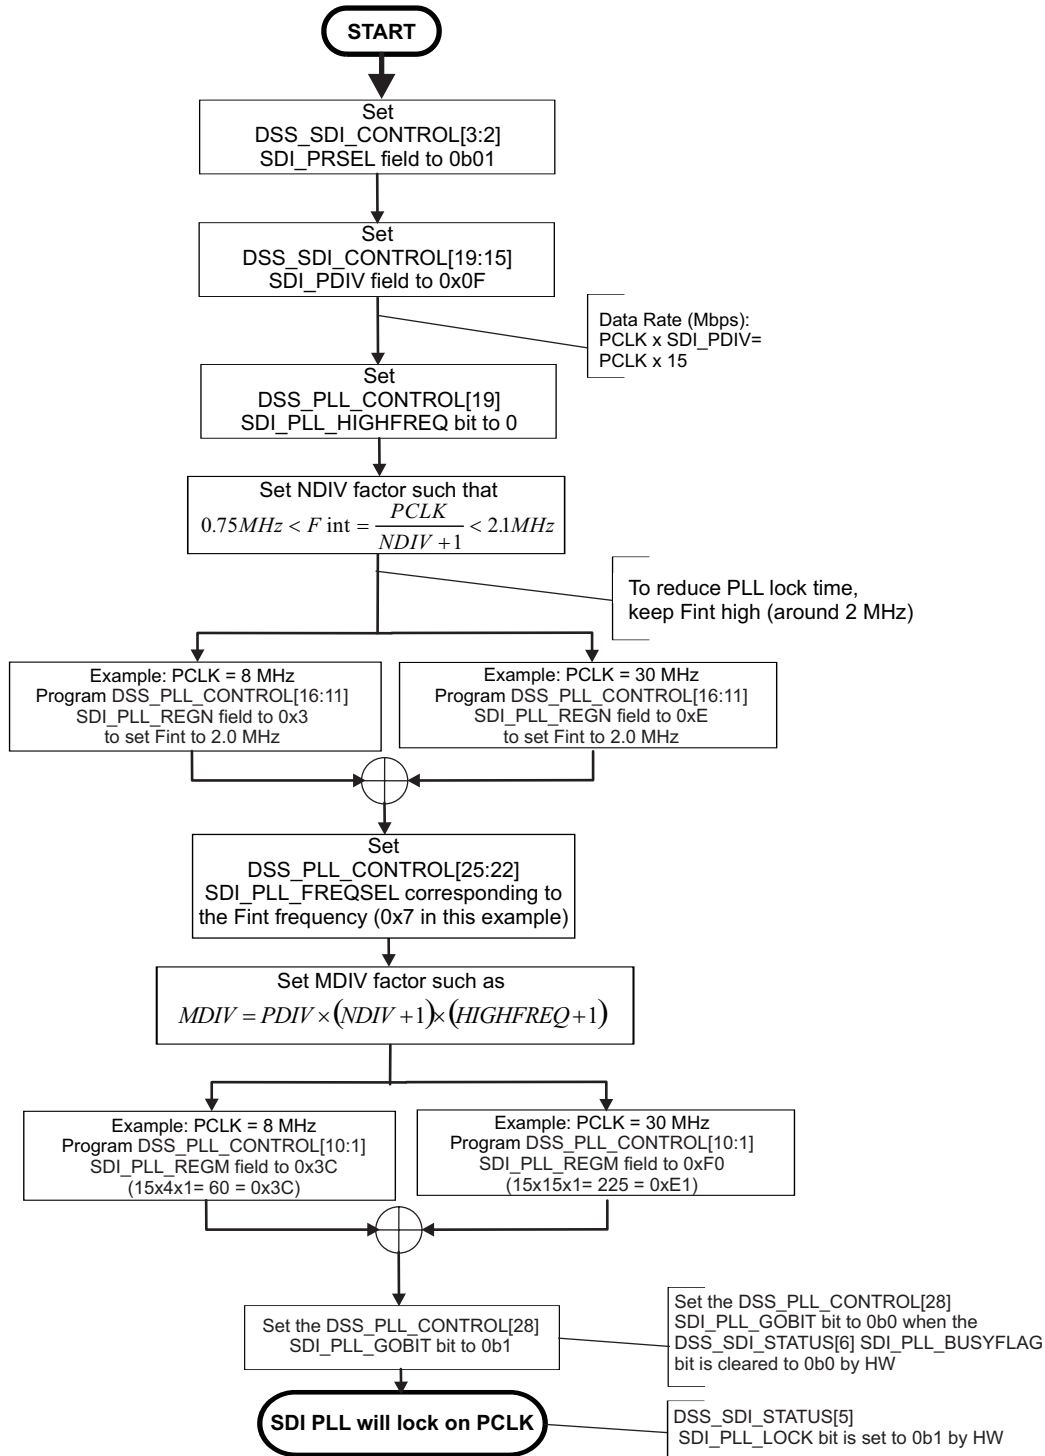

---

Figure 15-160. Flowchart SDI 1-Data Pair

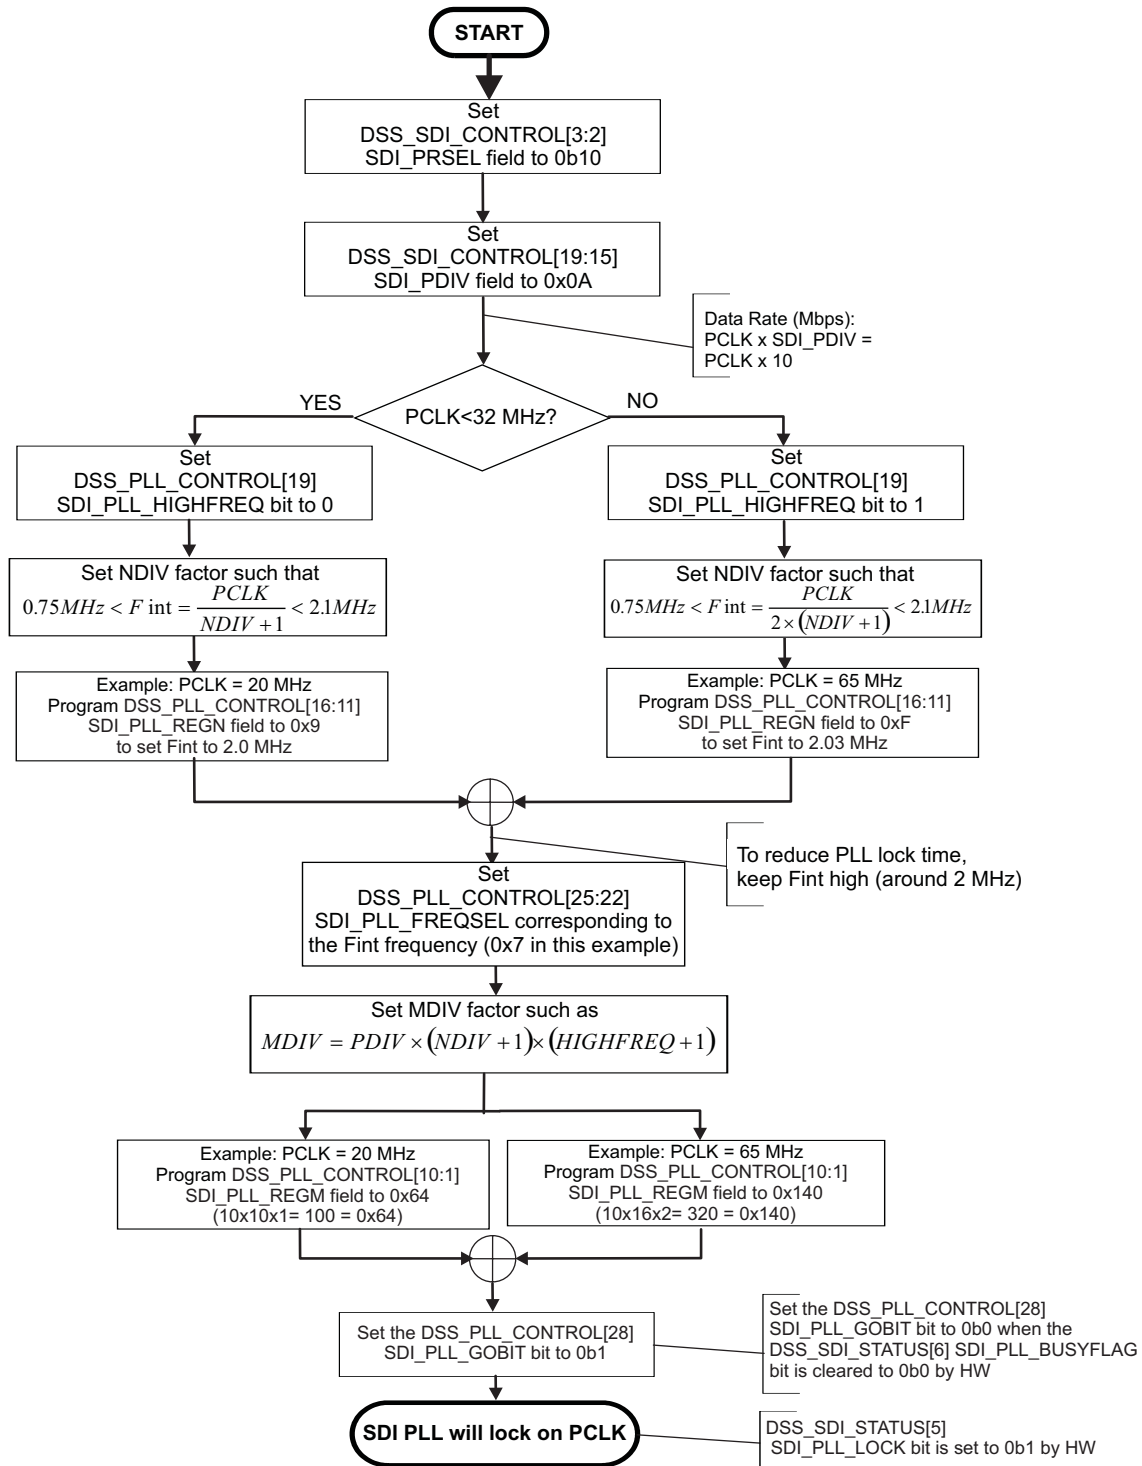

dss-128

Figure 15-161. Flowchart SDI 2-Data Pairs

dss-129

Figure 15-162. Flowchart SDI 3-Data Pairs

dss-130

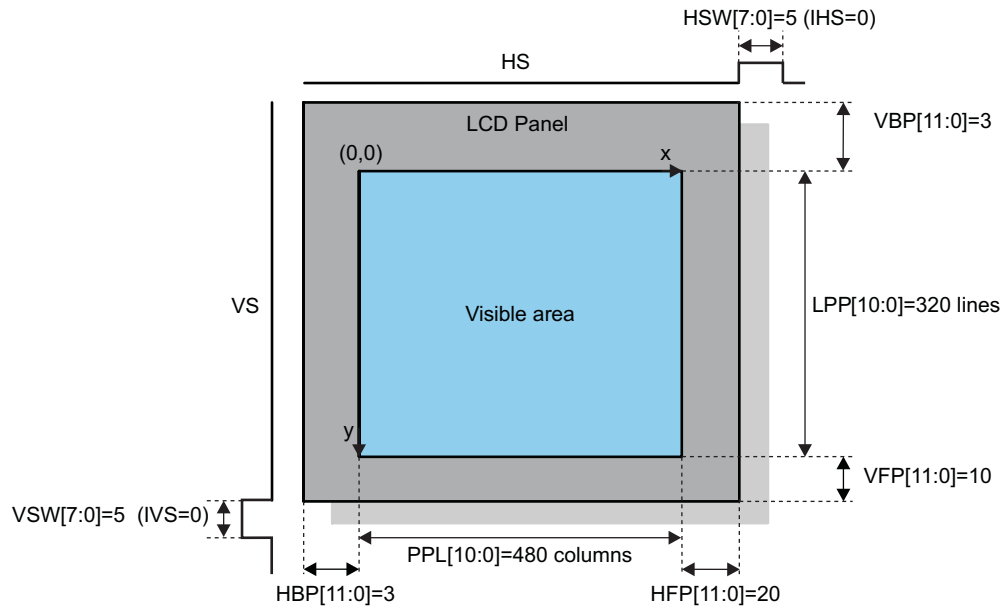

**CAUTION**

The PLL low-power mode (LP mode) can be activated with DSS.DSS\_PLL\_CONTROL[21] SDI\_PLL\_PLLLPMode bit. By setting this bit to 1, software users reduce the power and increases the jitter. In LP mode, there is no effect on lock time; but in this mode, the SDI PLL allows only 0.75-2.1MHz range (DSS.DSS\_PLL\_CONTROL[25:22] SDI\_PLL\_FREQSEL bit field value between 0x3 and 0x7). If software users are using the range 7.5 MHz to 21 MHz (DSS.DSS\_PLL\_CONTROL[25:22] SDI\_PLL\_FREQSEL bit field value between 0xB and 0xF) in non-LP mode, and then switching to LP mode and setting the PLL in the range of 0.75 MHz to 2.1 MHz, there will be an effect on the lock time.

**15.6.3.3 Application Example: HVGA Display**

The following example details the SDI PLL settings for a half-VGA display with the following parameters shown in Figure 15-163.

**Figure 15-163. HVGA Display**

dss-131

**15.6.3.3.1 HVGA Display**

- Display resolution: 320 x 480
- Frame refresh rate: 58.4 Hz
- Vertical visible pixel: 480 lines
- Vertical front porch: 20 lines
- Vertical sync: 5 lines
- Vertical back porch: 3 lines
- Horizontal visible pixel: 320 columns
- Horizontal front porch: 10 columns
- Horizontal sync: 5 columns
- Horizontal back porch: 3 columns

The calculation of the total number of pixel and Blanking overhead is as follows:

- Visible area pixel count:  $480 \times 320 = 153600$  pixel
- Total frame pixel count:  $(480 + 20 + 5 + 3) \times (320 + 10 + 5 + 3) = 171704$  pixel
- Blanking overhead:  $(171704 - 153600)/153600 = 11.8\%$

This application requires the following SDI parameters:

- Pixel clock frequency:  $171704 \times 58.4 \text{ Hz} = 10.03 \text{ MHz}$
- Serial data rate:
  - 1-channel mode:  $10.03 \text{ MHz} \times 30 \text{ bit/channel} = 300.9 \text{ Mbps}$
  - 2-channel mode:  $10.03 \text{ MHz} \times 15 \text{ bit/channel} = 150.45 \text{ Mbps}$

#### 15.6.3.3.2 SDI PLL Settings for 1-Channel Mode:

- 1-data pair: Set [DSS\\_SDI\\_CONTROL\[3:2\]](#) SDI\_PRSEL bit field to 0b00.
- Set the [DSS\\_SDI\\_CONTROL\[19:15\]](#) SDI\_PDIV bit field to 0x1E.
- Set the [DSS\\_PLL\\_CONTROL\[19\]](#) SDI\_PLL\_HIGHFREQ bit to 0.
- Set the [DSS\\_PLL\\_CONTROL\[16:11\]](#) SDI\_PLL\_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the [DSS\\_PLL\\_CONTROL\[25:22\]](#) SDI-PLL\_FREQSEL bit field to 0x7.
- Set [DSS\\_PLL\\_CONTROL\[10:1\]](#) SDI\_PLL\_REGM bit field to 0x96 ( $30 \times 5 \times 1 = 150 = 0x96$ ).

#### 15.6.3.3.3 SDI PLL Settings for 2-Channel Mode:

- 2-data pair: Set [DSS\\_SDI\\_CONTROL\[3:2\]](#) SDI\_PRSEL bit field to 0b01.
- Set the [DSS\\_SDI\\_CONTROL\[19:15\]](#) SDI\_PDIV bit field to 0x0F.
- Set the [DSS\\_PLL\\_CONTROL\[19\]](#) SDI\_PLL\_HIGHFREQ bit to 0.
- Set the [DSS\\_PLL\\_CONTROL\[16:11\]](#) SDI\_PLL\_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the [DSS\\_PLL\\_CONTROL\[25:22\]](#) SDI-PLL\_FREQSEL bit field to 0x7.
- Set [DSS\\_PLL\\_CONTROL\[10:1\]](#) SDI\_PLL\_REGM bit field to 0x4B ( $15 \times 5 \times 1 = 75 = 0x4B$ ).

### 15.6.4 How to Interface OMAP Device With SN65LVDS302 Receiver for an XGA Display Application

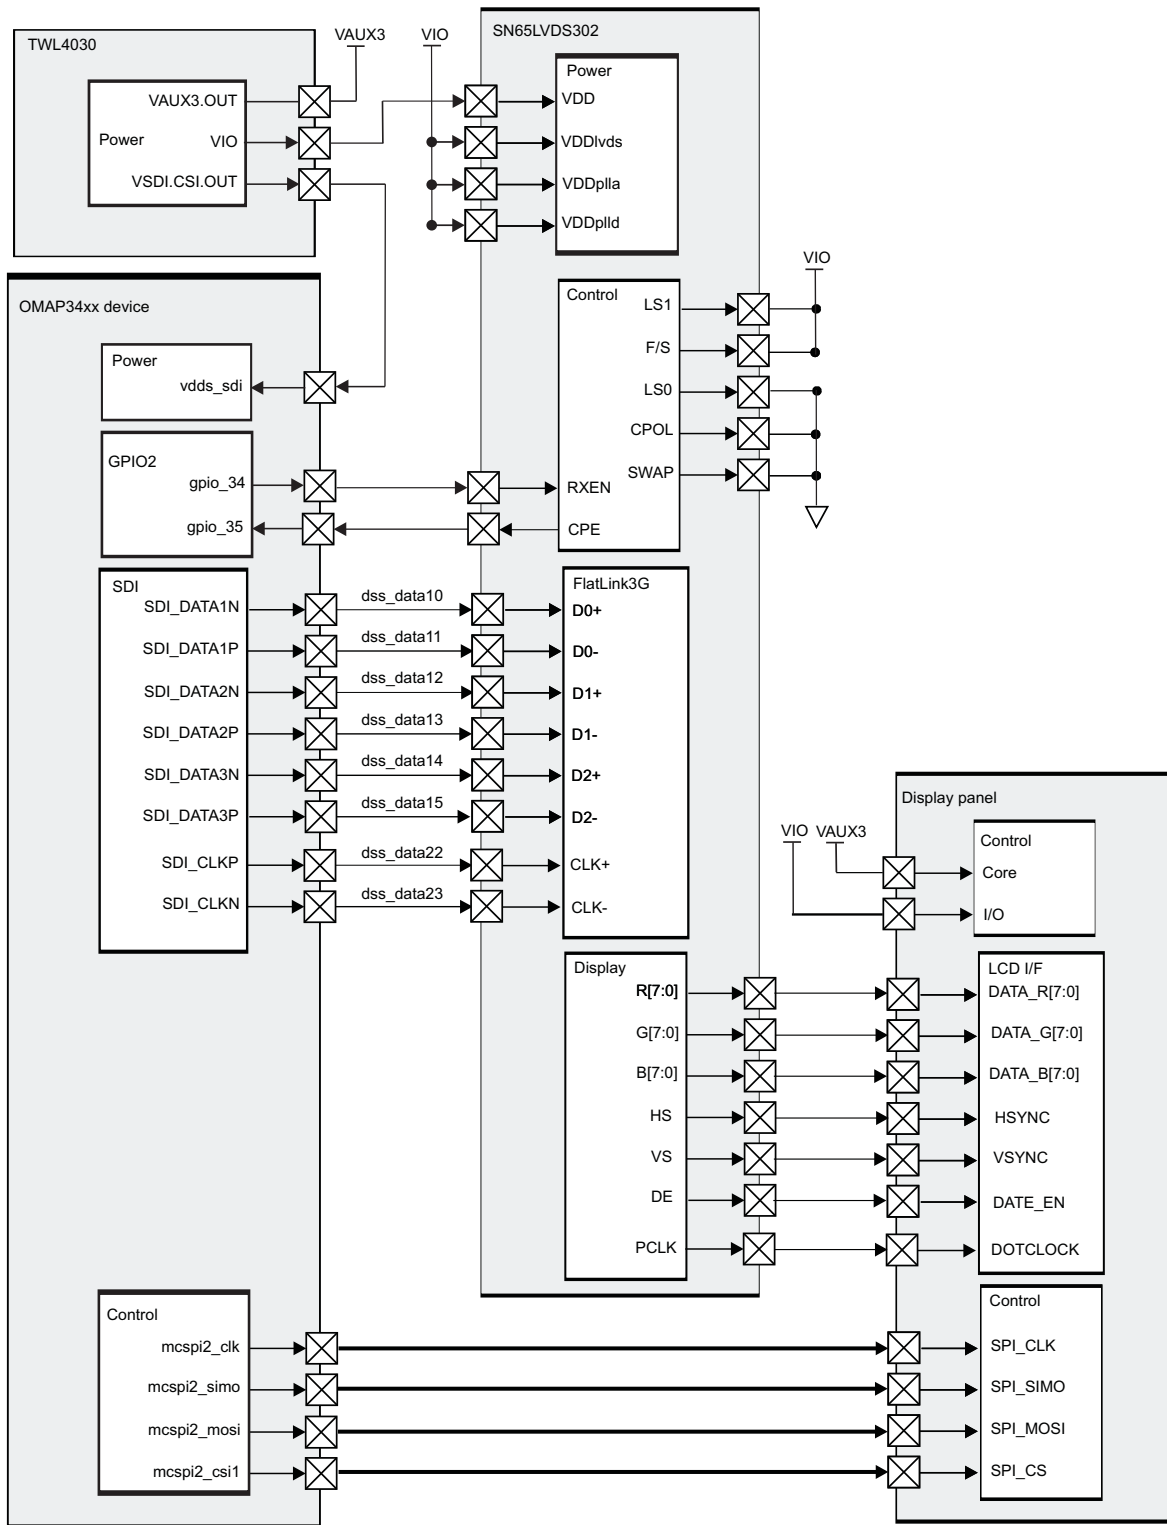

Texas Instruments Inc. provides a full FlatLink3G solution with the device associated to a SN65LVDS302 receiver. This section will also detail the hardware connections between these two devices and the basic software settings

This use case is based on the usage of a large (XGA) 16 Mega colors display requiring the three data channels and the complete output data bus to be used. Some adaptations may be adopted if the device is used in a less demanding use case

15.6.4.1 Hardware Connections

Figure 15-164 details the hardware connections with the device, the SN65LVDS302 receiver, the display panel and the power IC. The power IC can be the TWL4030 companion chip

Figure 15-164. Hardware Connections for FlatLink3G Application

108-132

---

**Note:** The SN65LVDS302 device was design-optimized for robustness to operate reliably in a dense environment with other digital switching ICs. In cell phone designs, the SN65LVDS302 often shares a power supply with the LCD display driver provided through the FPC interconnect. To minimize the power supply noise floor it is suggested to provide good decoupling near the SN65LVDS302 power pins. Using four capacitors (2x0.01F and 2x0.1F) was found to provide good performance. At the very least, it is recommended to install one 0.1F and one 0.01F capacitor near the SN65LVDS302. To avoid large current loops and trace inductance, the trace length between decoupling cap and IC power inputs pins must be minimized. Placing the capacitor underneath the SN65LVDS302 device on the bottom of the PCB is often a good choice

---

### 15.6.4.2 SN65LVDS302 Receiver Description

SN65LVDS302 is a serial interface receiver which converts the Flatlink™3G signals (3 sub-LVDS data pairs) into 27 signals (24 RGB bits, HS, VS and DE signals). It also provides a pixel clock (4 MHz to 65 MHz) which is formed from the sub-LVDS input clock pair, internally multiplied for data deserialization and then divided by same factor.

The device may operate in different modes, depending on the input data format. One, two or all of the three data pairs will be used, following the LS0 and LS1 configuration. The clock division rate will automatically be selected from 30 to 10. Pixel clock polarity can be chosen using the CPOL signal

The output bus order is configurable by SWAP pin configuration (R[7:0], G[7:0], B[7:0] or B[0:7], G[0:7], R[0:7]). Furthermore, the CMOS outputs rising/falling edges will be selected between slow or fast depending on F/S input to fit display timing constraints with regards to EMI and consumption consequences.

In the XGA display application detailed in Figure 7, the configuration is the following:

- LS1 = 1 and LS0 = 0: 3-data pairs mode is selected
- SWAP = 0: The data output format is R[7:0], G[7:0], B[7:0]
- F/S = 1: The CMOS bus time rise is selected in fast output
- CPOL = 0: The output clock polarity is rising edge

For more details on SN65LVDS302 receiver, please see the SN65LVDS302 data sheet ([SLLS733](#))

The RXEN signal will enable the OMAP device to control SN65LVDS302 activity which will signal channel parity error through CPE signal. These two previous signals are connected to OMAP GPIO2 module

### 15.6.4.3 SDI Software Settings

#### 15.6.4.3.1 SDI Configuration

To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC\_CONTROL[3] STNTFT bit to 0b1 (active matrix display operation mode)
- Set the DSS.DISPC\_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS\_SDI\_CONTROL[1:0] SDI\_BWSEL bit field to 0x2 (color depth is 24 bits)

#### 15.6.4.3.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC\_POL\_FREQ[16] RF bit to 0b1 for driving HSYNC and VSYNC on the rising edge of PCLK.
- Set the DSS.DISPC\_POL\_FREQ[17] ONOFF bit to 0b1.
- Clear the DSS.DISPC\_POL\_FREQ[14] IPC bit to 0b0 for driving the pixel data on the rising edge of PCLK
- Set the DSS.DISPC\_CONTROL[29] LCDENABLEPOL bit to 0b1 for setting the LCD-enable signal active high.

The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:

- Clear the DSS.DISPC\_POL\_FREQ[13] IHS bit to 0b0 for setting HSYNC active high.
- Clear the DSS.DISPC\_POL\_FREQ[12] IVS bit to 0b0 for setting VSYNC active high.
- Clear the DSS.DISPC\_POL\_FREQ[15] IEO bit to 0b0 for setting the data enable active high.

### 15.6.4.3.3 SDI PLL Configuration

The SDI module settings for an XGA display application with 20% blanking overhead are detailed in this section.

- XGA display: 1024 x 768 = 786432 pixels
- 20% blanking overhead: 157286 pixels
- Visible are pixel count: 786432 + 157286 = 943718
- Frame Refresh Rate: 60 Hz
- Pixel Clock Frequency: 943718 x 60 = 56.6 MHz (in 20-65 MHz range for 3-data pairs).
- Serial Data rate: 3-channel mode : 56.6 MHz x 10 bit/channel = 566 Mbps

#### 15.6.4.3.3.1 SDI PLL settings for 3-Channel Mode:

- 3-data pair: Set DSS\_SDI\_CONTROL[3:2] SDI\_PRSEL bit field to 0b10
- Set the DSS\_SDI\_CONTROL[19:15] SDI\_PDIV bit field to 0x0A
- Set the DSS\_PLL\_CONTROL[19] SDI\_PLL\_HIGHFREQ bit to 1 as PCLK>32 MHz
- Set the DSS\_PLL\_CONTROL[16:11] SDI\_PLL\_REGN bit field to 0xE. Thus Fint will be set to 2.02 MHz
- Set the DSS\_PLL\_CONTROL[25:22] SDI\_PLL\_FREQSEL bit field to 0x7
- Set DSS\_PLL\_CONTROL[10:1] SDI\_PLL\_REGM bit field to 0x12C ( $10 \times (14+1) \times 2 = 300 = 0x12C$ )

Set the SDI\_PLL\_CONTROL[27:26] SDI\_PLL\_LOCKSEL bit field to 0b00 to select the phase lock criteria to 0b00 (recommended for FlatLink3G mode)

### 15.6.4.4 SN65LVDS302 Receiver Settings

#### 15.6.4.4.1 Receiver Power-Up

At power up, the receiver is enabled immediately if RXEN=1 (enters Acquire mode) and disabled if RXEN=0 (enters shutdown mode). The receiver may be turned off at any time by pulling RXEN low for at least 10  $\mu$ s. This disables the CMOS drivers and turns off the receiver PLL, putting the device in shutdown mode. The RXEN signal is connected to the gpio\_34 pin of the device. Thus the GPIO2 module can control the receiver power-up.

---

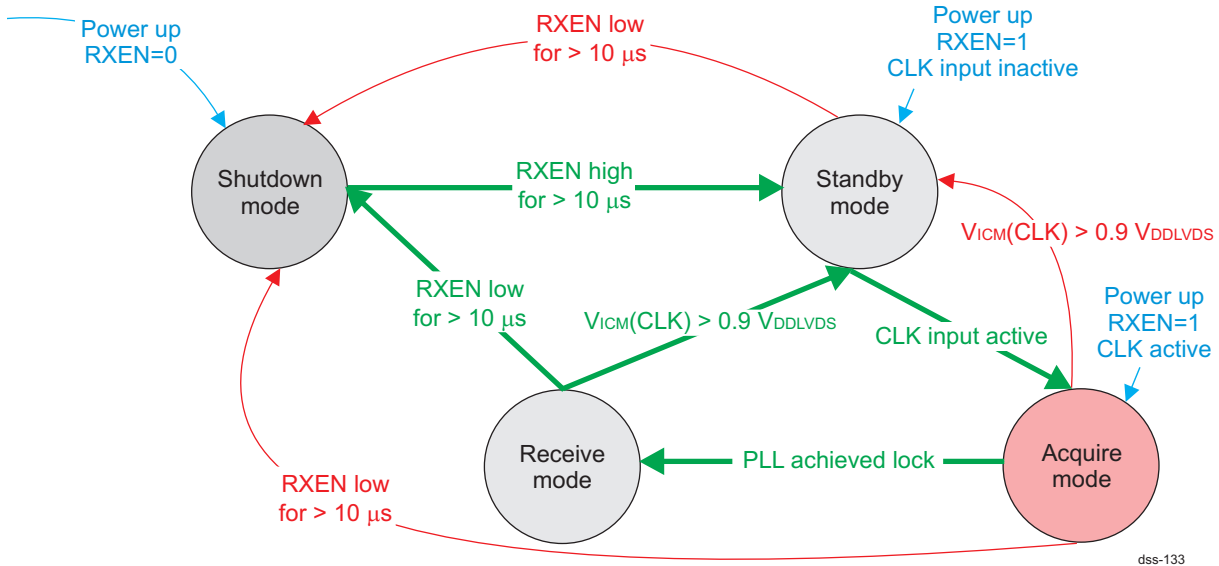

**Note:** The RXEN input incorporates glitch suppression logic to avoid unwanted switching. The input must be pulled continuously low for at least 10  $\mu$ s to force the receiver to enter shutdown. The gpio\_34 signal must be set continuously high by the OMAP device for at least 10  $\mu$ s to activate the receiver. An input pulse shorter than 5  $\mu$ s is interpreted as a glitch and is ignored.

---

### 15.6.4.4.2 Receiver Modes and Transitions

Figure 15-165 details the SN65LVDS302 receiver modes and transitions.

**Figure 15-165. SN65LVDS302 Receiver Modes and Transitions**

dss-133

#### 15.6.4.4.2.1 Modes Description

- Shutdown mode**  
 The SN65LVDS302 receiver may be put in Shutdown mode by holding the RXEN pin low. This turns off most of the receiver circuitry including the Sub-LVDS receivers, PLL, and deserializers. The Sub-LVDS input impedance remains 100- while any input signal becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Shutdown mode will be nearly zero.
- Standby mode**  
 The SN65LVDS302 receiver will enter the Standby mode when the SN65LVDS302 receiver is not in Shutdown mode but the clock input common mode range on the Sub-LVDS clock input shifts to VDDLVS. The CLK input incorporates a pull-up circuitry. This circuit will shift the Sub-LVDS clock input common mode voltage to VDDLVS in the absence of any input signal. All circuitry, except for the Sub-LVDS clock input Standby monitor will be shutdown. The Sub-LVDS input impedance remains 100- while any input signal on the data inputs D0, D1, and D2 becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Standby mode will be very low.
- Active Modes**  
 The SN65LVDS302 receiver will be in active mode when the device is enabled by pulling RXEN high and VICM on the CLK input is driven below  $0.9 \times V_{DD}$  by an external input signal. Current draw in active mode will be dependent on operating frequency and the number of data transitions in the data payload.
- Acquire Mode (PLL approaches lock)**  
 While the SN65LVDS302 receiver is enabled and a Sub-LVDS clock input present, the receiver PLL will pursue lock to the input clock. As long as the PLL is not locked the output data bus will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low.
- Receive Mode**  
 When the receiver PLL achieves lock, the receiver enters the normal receive mode with the output bus presenting the deserialized data.

### 15.6.4.4.2 Mode Transitions

**Table 15-82. SN65LVDS302 Receiver Mode Transitions**

Mode Transition	Use Case	Transition Specifics
Shutdown to Standby	Drive RXEN high to enable receiver	<ul style="list-style-type: none"> <li>• 1. RXEN high for longer than 10 <math>\mu</math>s</li> <li>• 2. Receiver enters Standby mode                             <ul style="list-style-type: none"> <li>– a. R[0:7]=G[0:7]=B[0:7]=VS=HS remain high and DE=PCLK low</li> <li>– b. receiver turns on clock input monitor</li> </ul> </li> </ul>
Standby to acquire	Transmitter activity detected	<ul style="list-style-type: none"> <li>• 1. CLK input monitor detects clock input activity</li> <li>• 2. Outputs remain static</li> <li>• 3. the receiver PLL becomes enabled</li> </ul>
Acquire to Receive	Link is ready to receive data from OMAP SDI module.	<ul style="list-style-type: none"> <li>• 1. PLL is active and achieves lock within 2 <math>\mu</math>s</li> <li>• 2. D1, D2, and D3 become active</li> <li>• 3. first Data word was recovered</li> <li>• 4. parallel output bus switches from static output pattern to output first valid data word</li> </ul>
Receive to Standby	Receiver requested to enter Standby mode by input common mode voltage $V_{ICM} > 0.9 V_{DDLVDs}$ (that is, transmitter output clock turns high-impedance)	<ul style="list-style-type: none"> <li>• 1. Transmitter disables outputs</li> <li>• 2. RX Input monitor detects <math>V_{ICM} &gt; 0.9 V_{DDLVDs}</math></li> <li>• 3. R[0:7]=G[0:7]=B[0:7]=VS=HS transition to high and DE=PCLK to low on next falling PLL clock edge</li> <li>• 4. PLL shuts down</li> <li>• 5. Clock activity input monitor remains active</li> </ul>
Receive/Standby to Shutdown	Turn off receiver	<ul style="list-style-type: none"> <li>• 1. RXEN pulled low for longer than 10 <math>\mu</math>s</li> <li>• 2. Receiver immediately puts all outputs into high impedance</li> <li>• 3. Most receiver blocks are shut down for least power consumption</li> </ul>

### 15.6.4.4.3 Parity Error Detection and Handling

The SN65LVDS302 receiver performs an error checking on the basis of a parity bit that is transmitted across the LVDS interface from the transmitting device. Once the SN65LVDS302 detects the presence of the clock and the receiver PLL has locked onto PCLK, then the parity is checked. The parity bit covers the 27-bit data payload (reserved bits are not covered in the parity calculations). Odd Parity bit signaling is used. The parity error is output on the output CPE pin:

- If the sum of the 27 data bits and the parity bit result in an odd number, the receive data are assumed to be valid and CPE output will be held low.
- If the sum equals an even number, parity error is declared and CPE output will indicate high for half a PCLK period.

The CPE output will be set with the data bit transition and cleared after 1/2 the data bit time. The receiver CPE output pin is connected to gpio\_35 pin. The OMAP device can use the gpio\_35 input pin to generate an IRQ, respectively GPIO2\_MPU\_IRQ for MPU subsystem and GPIO2\_IVA2\_IRQ for IVA2.2 subsystem. This will allow the OMAP device to count every detected parity error with a simple counter triggered by GPIO2 module interrupt request.

When a parity error is detected, the data on that PCLK cycle is not output. Instead, the last valid data from a previous PCLK cycle is repeated on the output bus. This is to prevent any bit error that may occur on the LVDS link from causing perturbations in VS, HS or DE that may be visually disruptive to the display panel.

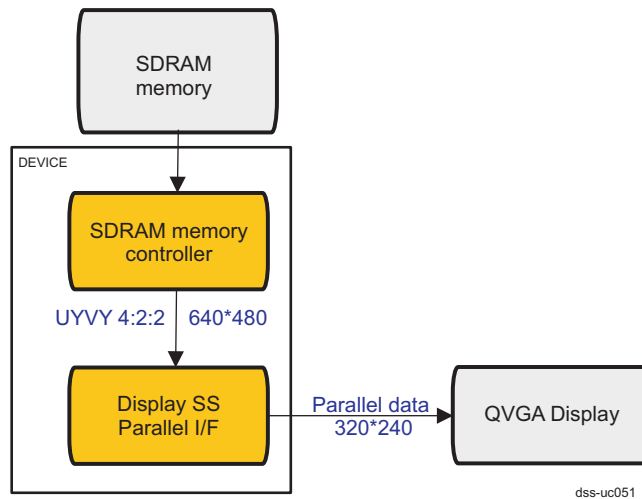

## 15.6.5 Camcorder Use Case: How to Configure the Display Subsystem When Connected With a QVGA LCD Panel

### 15.6.5.1 Overview

This section describes the configuration and used of a QVGA LCD panel through the parallel data interface (in RFBI by-pass mode).

The display subsystem reads each image from the SDRAM memory in the UYVY 4:2:2 format and converts it to a RGB18-666 pixel format to send to the QVGA LCD panel (see [Figure 15-166](#)).

**Figure 15-166. Overview**

The camcorder use case is configured as follows:

- Input Image: VGA 640\*480 pixels , UYVY 4:2:2 format
- Output Image Pixel: QVGA 320\*240 pixels , RGB18-666
- Pixel Clock (PCLK): 6 MHz to allow a video display of 60 frames per second
- No DMA requests to the system DMA, but the display subsystem uses its DMA controller to access the data into SDRAM
- VSYNC, SYNCLOST, VID1FIFOUNDERFLOW, and VID1ENDWINDOW interrupts used to monitor the video1 channel

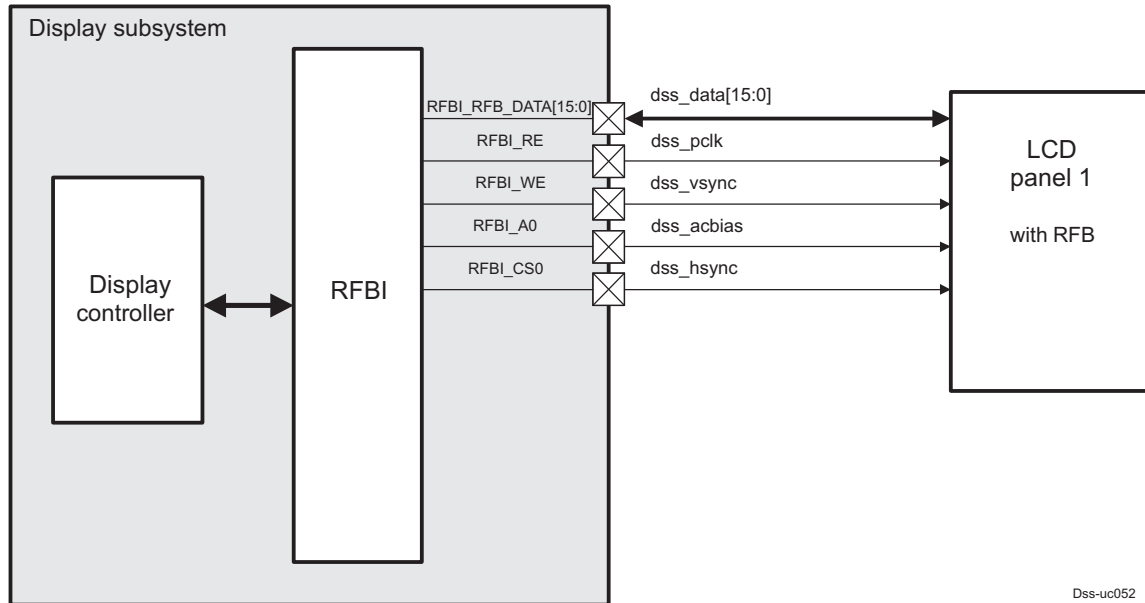

### 15.6.5.2 Environment

In this use case, the display subsystem is connected to a QVGA LCD panel by the parallel interface.

[Figure 15-167](#) details the OMAP device connections with the LCD panel.

Figure 15-167. Environment

Dss-uc052

### 15.6.5.2.1 LCD panel Features

The LCD panel includes the following features:

- Display format 320(H) x 240(V)
- Color mode: 18 bit/pixel R:5 G:6 B:5 (65 536 colors)

### 15.6.5.3 Data Path

In this use case, the display subsystem manages the following:

- Video stream (UYVY 4:2:2) between the SDRAM controller (SDRC) and the display controller through the internal DMA controller (L3 interconnect)
- Video stream (RGB16) between the display controller and the parallel module
- Video stream (parallel data) between the parallel module and the QVGA LCD panel

Figure 15-168 shows the data flow inside the display subsystem highlighted in red.

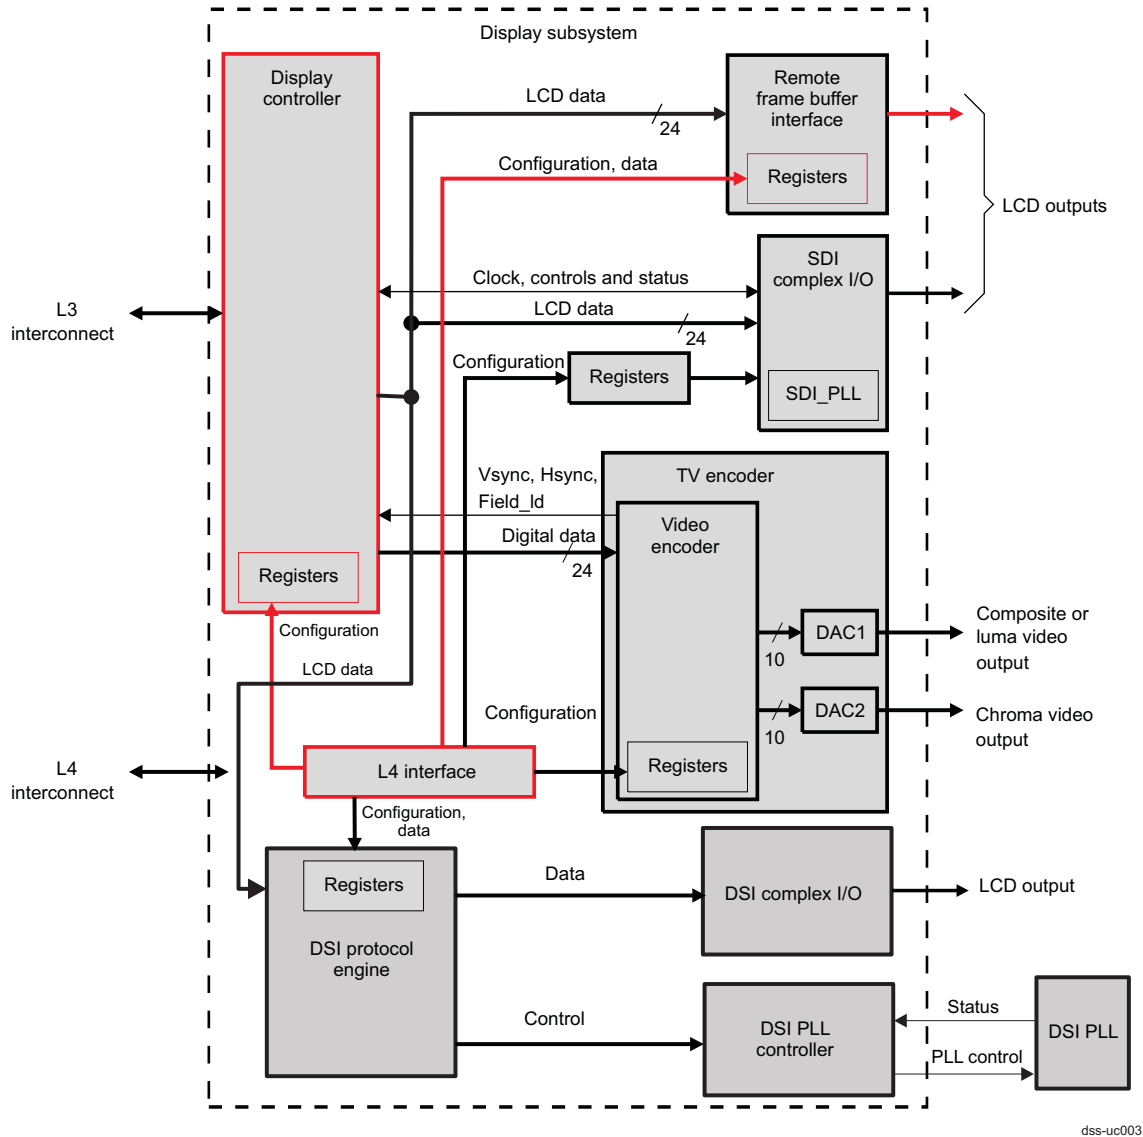

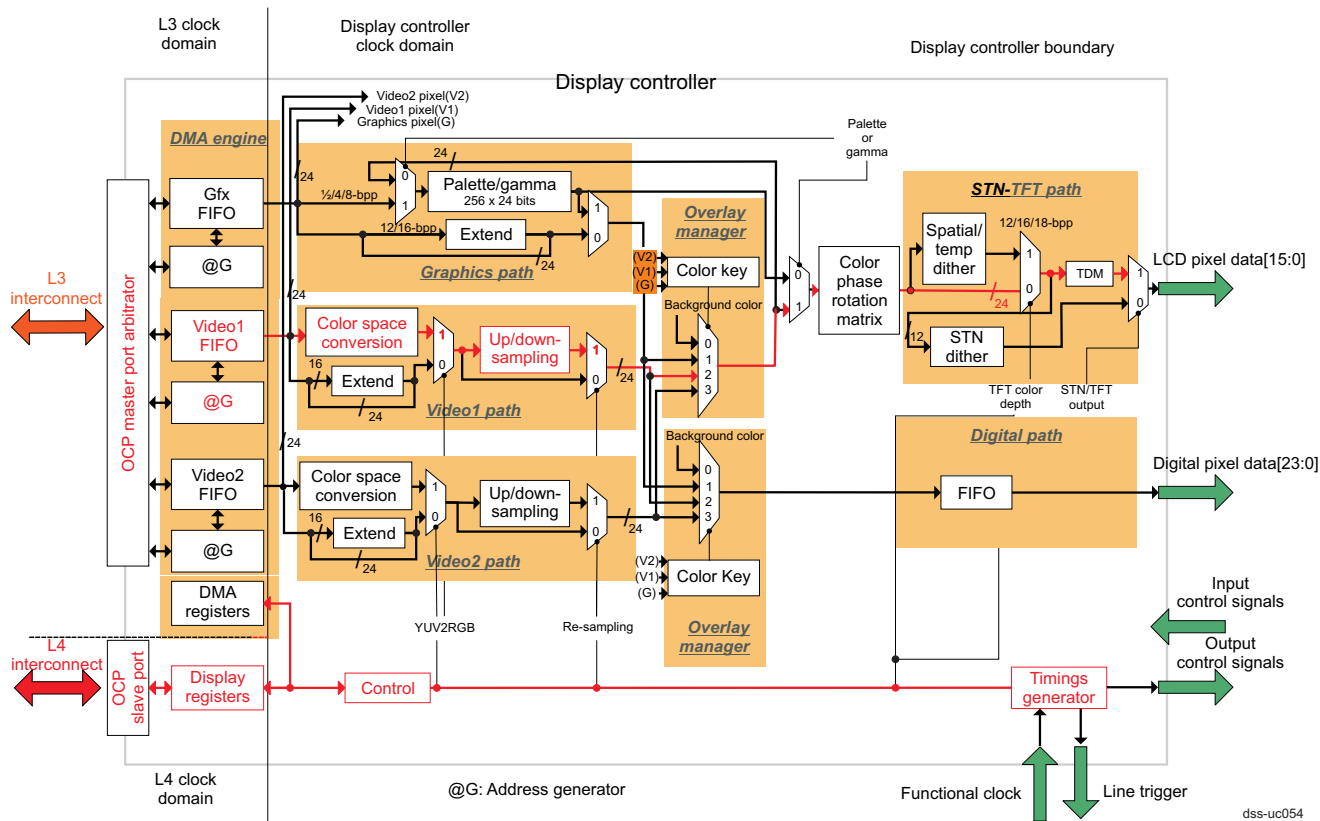

**Figure 15-168. Display Subsystem Data Flow**

Figure 15-169 shows the data flow inside the display controller submodule highlighted in red.

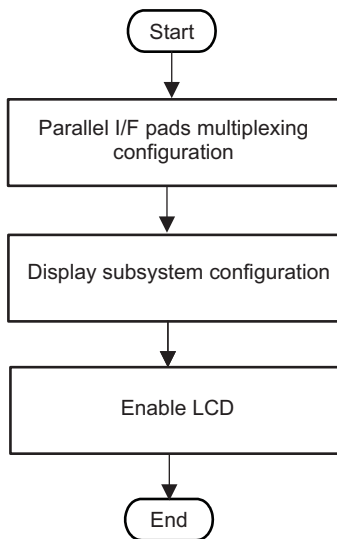

Figure 15-169. Display Controller Data Flow

### 15.6.5.4 Programming Flow

This section details the programming flow of the display panel configuration for the camcorder use case. The display panel is configured in 3 steps (see Figure 15-170).

Figure 15-170. Display Panel Configuration for the Camcorder Use Case

dss-uc055

Figure 15-171 shows the programming flow of the display subsystem initial configuration, which consists of four steps:

**Figure 15-171. Display Subsystem Configuration for Camcorder Use Case**

#### 15.6.5.4.1 Pads Multiplexing Configuration

All parallel pads are multiplexed in mode 1 on the dss\_data pins:

Table 15-83 shows all the System Control Module registers.

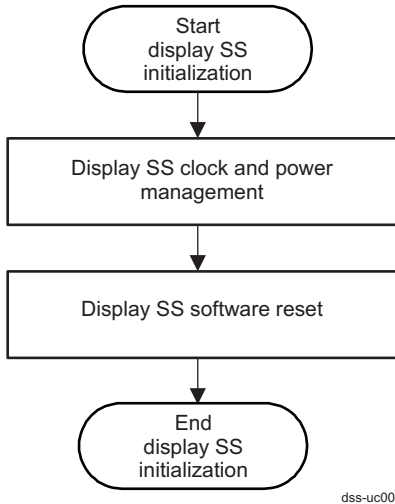

**Table 15-83. Registers Print for QVGA LCD panel Pads Multiplexing Configuration**

Register Name	Address	Value	Value Description
SCM.CONTROL_PADCONF_DSS_PCLK	0x4800 20D4	0x0110 0110	Configure dss_pclk and dss_hsync pads in mode 0
SCM.CONTROL_PADCONF_DSS_VSYNC	0x4800 20D8	0x0100 0110	Configure dss_vsync and dss_acbias pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA0	0x4800 20DC	0x0100 0100	Configure dss_data0 and dss_data1 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA2	0x4800 20E0	0x0100 0100	Configure dss_data2 and dss_data3 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA4	0x4800 20E4	0x0100 0100	Configure dss_data4 and dss_data5 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA6	0x4800 20E8	0x0100 0100	Configure dss_data6 and dss_data7 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA8	0x4800 20EC	0x0100 0100	Configure dss_data8 and dss_data9 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA10	0x4800 20F0	0x0100 0100	Configure dss_data10 and dss_data11 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA12	0x4800 20F4	0x0100 0100	Configure dss_data12 and dss_data13 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA14	0x4800 20F8	0x0100 0100	Configure dss_data14 and dss_data15 pads in mode 0

### 15.6.5.4.2 Display Subsystem Initialization

Figure 15-172 details the display subsystem initialization.

Figure 15-172. Display Subsystem Initialization

#### 15.6.5.4.2.1 Display Subsystem Clock and Power Management

The display subsystem clock (DSS1\_ALWON\_FCLK) is provided by the DPLL4 module in the PRCM (DPLL4\_M4\_X2). The software should set the following PRCM registers:

1. The DPLL4\_ALWON\_FCLKOUT clock is sourced by the system clock (SYS\_CLK) at 26 MHz and calculated as follows:

$$DPLL4\_ALWON\_FCLKOUT = \frac{SYS\_CLK(19.2\text{ MHz}) \times 2 \times M(0xE1)}{N(0x9) + 1} = 864\text{ MHz}$$

dss-uc020

Set the M multiplier to 225 by setting the PRCM.CM\_CLKSEL2\_PLL[18:8] PERIPH\_DPLL\_MULT bit field to 0xE1.

Set the N divider to 9 by setting the PRCM.CM\_CLKSEL2\_PLL[6:0] PERIPH\_DPLL\_DIV bit field to 0x09.

2. To follow the timing requirements for the use case, the DPLL4\_M4\_X2 clock frequency is calculated as follows:

$$DPLL4\_M4X2\_CLK = \frac{DPLL4\_ALWON\_FCLKOUT(864\text{ MHz})}{9} = 96\text{ MHz}$$

dss-ucE007

Set the DPLL4 ratio by programming to 0x9 the PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field.

3. Enable the display subsystem functional clock (DSS1\_ALWON\_FCLK): Set the PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 to 0x1.
4. Enable the display subsystem TV functional clock (DSS\_TV\_FCLK): Set the PRCM.CM\_FCLKEN\_DSS[2] EN\_TV to 0x1.
5. Enable the display subsystem interface clock (DSS\_L4\_ICLK): Set the PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS to 0x1.

Table 15-84 describes the registers from the PRCM to be configured for the display subsystem clock configuration step and the use case values.

**Table 15-84. Registers Print for Display Subsystem Clock Management**

Register Name	Address	Value	Value Description
PRCM.CM_FCLKEN_DSS	0x4800 4E00	0x0000 0005	Enable DSS1_LWON_FCLK and DSS_TV_FCLK
PRCM.CM_ICLKEN_DSS	0x4800 4E10	0x0000 0001	Enable DSS_L4_ICLK
PRCM.CM_CLKSEL2_PLL	0x4800 4D44	0x0000 E109	DPLL4 multiplier set to 0xE1 and divider set to 0x9
PRCM.CM_CLKSEL_DSS	0x4800 4E40	0x0001 0009	DPLL4 M4X2 divider set to 0x9

The display subsystem power management is programmed by the following PRCM registers:

1. Disable the autoidle mode: Set the PRCM.CM\_AUTOIDLE\_DSS register to 0x0.
2. Disable the DSS domain sleep dependency: Set the PRCM.CM\_SLEEPDEP\_DSS register to 0x0.
3. Disable the automatic transition between active and inactive: Set the PRCM.CM\_CLKSTCTRL\_DSS register to 0x0.

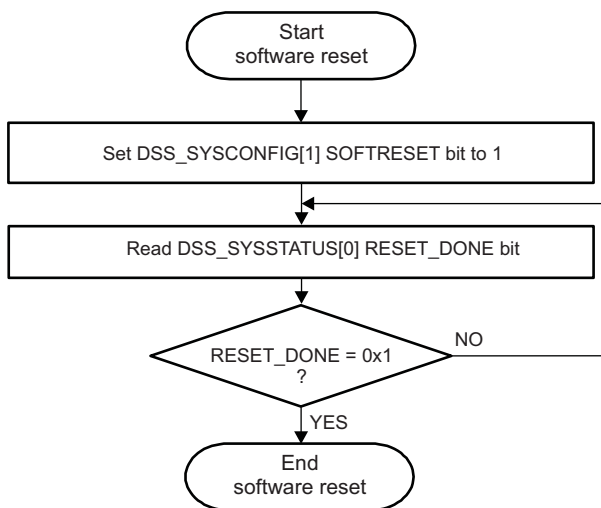

Table 15-85 describes the registers from the PRCM to be configured for the display subsystem power management step and the use case values.

**Table 15-85. Registers Print for Display Subsystem Power Management**

Register Name	Address	Value	Value Description
PRCM.CM_AUTOIDLE_DSS	0x48004E30	0x0000 0000	Disable autoidle mode
PRCM.CM_SLEEPDEP_DSS	0x48004E44	0x0000 0000	Disable the DSS domain sleep dependency
PRCM.CM_CLKSTCTRL_DSS	0x48004E48	0x0000 0000	Disable the automatic clock state transition

#### 15.6.5.4.2.2 Display Subsystem Software Reset

Perform a software reset as described in the following flowchart (see Figure 15-173).

**Figure 15-173. Software Reset Flowchart**

dss-uc008

**CAUTION**

To update the RESETDONE status bit correctly, all interface and functional clocks, even for the TV output, must be provided to the display subsystem.

Table 15-86 describes the registers to be configured for the display subsystem software reset step and the use case values.

**Table 15-86. Registers Print for Display Subsystem Software Reset**

Register Name	Address	Value	Value Description
<a href="#">DSS_SYSCONFIG</a>	0x4805 0010	0x0000 0002	Initiate a software reset. The <a href="#">DSS_SYSCONFIG[1]</a> SOFTRESET is automatically reset by hardware
<a href="#">DSS_SYSSTATUS</a>	0x4805 0014	0x0000 0001	The <a href="#">DSS_SYSSTATUS[0]</a> RESETDONE is set to 1 when the reset sequence is done

#### 15.6.5.4.3 Video1 Channel Configuration

The video1 channel is configured by programming the following steps:

1. Select the UYVY 4:2:2 format by programming the DSS.DISPC\_VID1\_ATTRIBUTES[4:1] VIDFORMAT bit field to 0xB.
2. Select the LCD data flow by programming the DSS.DISPC\_VID1\_ATTRIBUTES[16] VIDCHANNELOUT bit to 0x0.
3. Select the video DMA burst size to 16x32 by setting the DSS.DISPC\_VID1\_ATTRIBUTES[15:14] VIDBURSTSIZE to 0x2.
4. Program the image base address by setting the DSS.DISPC\_VID1\_BA0 register.
5. Program the FIFO thresholds as follows:  
To set the FIFO high threshold to 1023 bytes (maximum value allowed), set the DSS.DISPC\_VID1\_FIFO\_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field to 0x3FF.  
Set the FIFO low threshold as described in the following equation:

$$\text{VIDFIFOWHRESHOLD} = \text{VIDFIFOHIGHTHRESHOLD} (0x3FF) - \frac{\text{VIDBURSTSIZE}(16x32)}{8} = 959 (0x3BF)$$

dss-ucE009

- Program the DSS.DISPC\_VID1\_FIFO\_THRESHOLD[11:0] VIDFIFOWHRESHOLD to 0x3BF.
6. Program the windows X-position to 0 (first column starting on the left edge of the screen) and the window Y-position to 0 (first row starting at the top of the screen): Set the DSS.DISPC\_VID1\_POSITION[10:0] VIDPOSX and the DSS.DISPC\_VID1\_POSITION[26:16] VIDPOSY registers to 0x0.
  7. Program the window width to 320 by setting the DSS.DISPC\_VID1\_SIZE[10:0] VIDSIZEX to 0x13F.
  8. Program the window height to 240 by setting the DSS.DISPC\_VID1\_SIZE[26:16] VIDSIZEY to 0xEF.
  9. Program the picture width to 640 by setting the DSS.DISPC\_VID1\_PICTURE\_SIZE[10:0] VIDORGSIZEX to 0x27F.
  10. Program the picture height to 480 by setting the DSS.DISPC\_VID1\_PICTURE\_SIZE[26:16] VIDORGSIZEY to 0x1DF.
  11. Because the video format is in UYVY, software users must program the color conversion module as follows:  
To enable the color conversion module, set the DSS.DISPC\_VID1\_ATTRIBUTES[9] VIDCOLORCONVENABLE bit to 1.  
To select a limited range for color space conversion, set the DSS.DISPC\_VID1\_ATTRIBUTES[11] VIDFULLRANGE bit to 0.  
The DSS.DISPC\_VID1\_COEFi registers (with i = 0 to 4) have nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline 1:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-ucE010

The nine coefficient values for color space conversion from UYVY 4:2:2 to RGB are as follows:

RY = 298, RCb = 0, RCr = 409

GY = 298, GCb = (unsigned) (-11), GCr = (unsigned) (-208)

BY = 298, BCb = 517, BCr = 0

12. Configure the video1 channel for VRFB rotation settings as shown in [Table 15-87](#):

**Table 15-87. VRFB Rotation Configuration**

Rotation	Registers	Value
0 degree	DSS.DISPC_VID1_BA0	VBA0
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - iw) x ps + 1
90 degrees	DSS.DISPC_VID1_BA0	VBA90
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - ih) x ps + 1
180 degrees	DSS.DISPC_VID1_BA0	VBA180
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - iw) x ps + 1
270 degrees	DSS.DISPC_VID1_BA0	VBA270
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - ih) x ps + 1

In the use case context, the input video format is UYVY for a VGA display (640 \* 480). As a consequence, the VRFB configuration is as described in [Table 15-88](#).

**Table 15-88. VRFB Rotation Configuration for a VGA Display (UYVY format)**

Rotation	Registers	Value
0 degree	DSS.DISPC_VID1_BA0	VBA0
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	6273
90 degrees	DSS.DISPC_VID1_BA0	VBA90
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	7233
180 degrees	DSS.DISPC_VID1_BA0	VBA180
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	6273
270 degrees	DSS.DISPC_VID1_BA0	VBA270
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	7233

For more information on VRFB module and settings, see the VRFB use case and tips section in [Chapter 11, Memory Subsystem](#).

According to the rotation angle, program the DSS.DISPC\_VID1\_ATTRIBUTES[13] VIDROTATION and the DSS.DISPC\_VID1\_ATTRIBUTES[18] VIDROWREPEATENABLE bits as described in [Table 15-89](#).

**Table 15-89. Video Rotation Register Settings (UYVY Only)**

Rotation	Registers Field Name	Registers Field Value
0 degree	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

13. Because the video size is in 640 \* 480, the scaling unit must be used to downsample to a size of 320 \* 240 using a 3 taps configuration.

The video scaling block for the video pipeline 1 is set in downscaling for horizontal and vertical by setting the following bit field in DSS.DISPC\_VIDn\_ATTRIBUTES[6:5] :

- VIDRESIZEENABLE bit field to 0x03
- VIDHRESIZECONF bit field to 0x1
- VIDVRESIZECONF bit field to 0x1

14. Program the downscaling of 2 by setting DSS.DISPC\_VIDn\_FIR to 0x0800 0800.

All taps coefficients are programmed as in [Table 15-90](#).

[Table 15-90](#) describes the registers to be configured for the video1 channel configuration step and the use case values.

**Table 15-90. Registers Print for Video1 Channel Configuration**

Register Name	Address	Value	Value Description
DISPC_VID1_ATTRIBUTES	0x4805 04CC	0x0000 8216 (for 0-degree rotation)	See the programming steps described above for details.
DISPC_VID1_BA0	0x4805 04BC	Base address value	Base address for an image in SDRAM. Depends on the rotation angle (see <a href="#">Table 15-88</a> ).
DISPC_VID1_FIFO_THRESH_OLD	0x4805 04D0	0x03FF 03BF	FIFO high and low thresholds for DMA request generation
DISPC_VID1_POSITION	0x4805 04C4	0x0000 0000	No X-position and Y-position offsets
DISPC_VID1_SIZE	0x4805 04C8	0x00EF 013F	QVGA display:320*240
DISPC_VID1_PICTURE_SIZE	0x4805 04E4	0x01DF 027F	VGA display: 640*480
DISPC_VID1_CONV_COEF0	0x4805 0530	0x0199 012A	Color space conversion: RCR and RY coefficients
DISPC_VID1_CONV_COEF1	0x4805 0534	0x012A 0000	Color Space Conversion: GY and RCB coefficients
DISPC_VID1_CONV_COEF2	0x4805 0538	0x07F5 0730	Color Space Conversion: GCB and GCR coefficients
DISPC_VID1_CONV_COEF3	0x4805 053C	0x0000 012A	Color Space Conversion: BCR and BY coefficients
DISPC_VID1_CONV_COEF4	0x4805 0540	0x0000 0205	Color Space Conversion: BCB coefficient
DISPC_ROW_INC	0x4805 04D8	Image row increment	Image stride. Depends on the rotation angle (see <a href="#">Table 15-88</a> ).
DISPC_PIXEL_INC	0x4805 04DC	0x0000 0001	Pixel increment set to 1 because VRFB module is in charge of rotating the image
DISPC_VID1_FIR	0x4805 04E0	0x0800 0800	Vertical and horizontal ratio for downscaling

#### 15.6.5.4.4 Interrupts Enable

The interrupts enable stage is as follows:

1. To clear all display controller IRQs, set the DSS.DISPC\_IRQSTATUS register to 0xFFFF.
2. To enable the VSYNC interrupt, set the DSS.DISPC\_IRQENABLE[1] VSYNC bit to 1.
3. To enable the VID1FIFOUNDERFLOW interrupt, set the DSS.DISPC\_IRQENABLE[10] VID1FIFOUNDERFLOW bit to 1.
4. To enable the ENDVID1WINDOW interrupt, set the DSS.DISPC\_IRQENABLE[11] ENDVID1WINDOW bit to 1.
5. To enable the SYNCLOST interrupt, set the DSS.DISPC\_IRQENABLE[14] SYNCLOST bit to 1.

Table 15-91 describes the registers to be configured for the interrupts enable step and the use case values.

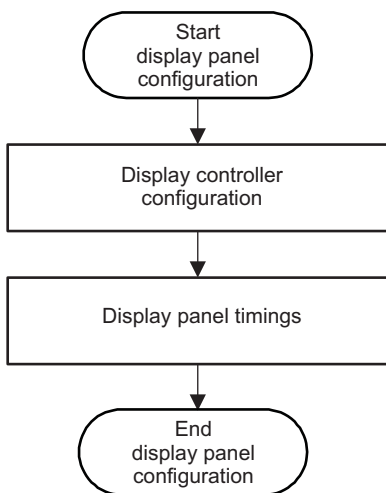

**Table 15-91. Registers Print for Interrupts Enable**

Register Name	Address	Value	Value Description
DISPC_IRQSTATUS	0x4805 0418	0xFFFF FFFF	Clear all DISPC interrupt requests. This register is automatically reset by hardware.
DISPC_IRQENABLE	0x4805 041C	0x0000 4C02	Enable the VSYNC, VID1FIFOUNDERFLOW, ENDVID1WINDOW, and SYNCLOST IRQs.

#### 15.6.5.4.5 Display Panel Configuration

Figure 15-174 shows the structure of the display panel configuration stage:

**Figure 15-174. Display Panel Configuration Flowchart**

dss-uc011

##### 15.6.5.4.5.1 Display Controller Configuration

To interface the DISPC with the QVGA LCD panel (320\*240), the following settings are required:

1. The QVGA LCD panel is an active matrix: set the DSS.DISPC\_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode).
2. Select 16-bit data output by setting the DSS.DISPC\_CONTROL[9:8] TFTDATALINES bit field to 0x1.
3. Bypass the RFBI module by setting the DSS.DISPC\_CONTROL[16:15] GPOUT[1:0] bit field to 0x3.
4. Select the color panel option by setting the DSS.DISPC\_CONTROL[2]MONOCOLOR bit to 0x0.
5. Program the LCD enable signal active high by setting the DSS.DISPC\_CONTROL[29] LCDENABLEPOL bit to 1.
6. Disable the free-running pixel clock by setting the DSS.DISPC\_CONTROL[27] PCKFREEENABLE bit to 0.
7. Program the number of lines per panel to 240 by setting the DSS.DISPC\_SIZE\_LCD[26:16] LPP bit field to 0xEF (239 = 240 -1).
8. Program the number of pixels per line to 320 by setting the DSS.DISPC\_SIZE\_LCD[10:0] PPL bit field to 0x13F (319 = 320 -1).
9. The palette module is bypassed: set the DSS.DISPC\_CONFIG[2:1] LOADMODE bit field to 0x2 (frame data only).

### 15.6.5.4.5.2 Display Panel Timings

Figure 15-175 details the timing values description for the QVGA LCD panel.

**Figure 15-175. QVGA LCD Panel Timings**

The following steps define the timing generation of HSYNC/VSYNC signals based on the QVGA LCD panel specification:

1. Program the horizontal front porch to 9 by setting the DSS.DISPC\_TIMING\_H[19:8] HFP bit field to 0x8 (9-1).
2. Program the horizontal back porch to 60 by setting the DSS.DISPC\_TIMING\_H[31:20] HBP bit field to 0x3B (60-1).
3. Program the horizontal synchronization pulse width to 2 by setting the DSS.DISPC\_TIMING\_H[7:0] HSW bit field to 0x1 (2-1).
4. Program the vertical front porch to 1 by setting the DSS.DISPC\_TIMING\_V[19:8] VFP bit field to 1.
5. Program the vertical back porch to 5 by setting the DSS.DISPC\_TIMING\_V[31:20] VBP bit field to 5.
6. Program the vertical synchronization pulse width to 0 by setting the DSS.DISPC\_TIMING\_V[7:0] VSW bit field to 0.
7. For QVGA LCD panel, the line clock signal is active high and inactive low. As a consequence, invert HSYNC by setting the DSS.DISPC\_POL\_FREQ[13] IHS bit to 0.
8. For QVGA LCD panel, the frame clock signal is active high and inactive low. As a consequence, invert VSYNC by setting the DSS.DISPC\_POL\_FREQ[12] IVS bit to 0.
9. Drive HSYNC and VSYNC on the falling edge of PCLK by setting the DSS.DISPC\_POL\_FREQ[16] RF bit to 0 and the the DSS.DISPC\_POL\_FREQ[17] ONOFF bit to 0.
10. Drive the pixel data on the rising edge of PCLK by clearing the DSS.DISPC\_POL\_FREQ[14] IPC bit to 0.
11. Set the data enable active high by clearing the DSS.DISPC\_POL\_FREQ[15] IEO bit to 0.

The visible pixel count is  $320 * 240 = 76\ 800$  pixels.

The Total Frame Pixel Count (with the values given above) is  $(320+8+59+1) * (240+5+1+0) = 95\ 448$  pixels.

The camcorder application displays 60 frame per second.

The pixel clock required for 60 fps is:  $95\ 448 * 60\ \text{Hz} = 5,72688\ \text{MHz}$ .

On the other hand, the pixel clock is defined by the following equation:

$$\text{PixelClock} = \frac{\text{Functional Clock}}{\text{LCD factor} \times \text{PCD factor}} \quad \text{dss-ucE013}$$

To program the pixel clock to 5.72688 MHz, software users must set:

1. Set the DSS.DISPC\_DIVISOR[23:16] LCD bit field to 0x2.

$$\text{LogicClock} = \frac{\text{DSS1\_ALWON\_FCLK}}{2} = 48 \text{ Mhz} \quad \text{dss-ucE014}$$

2. Set the DSS.DISPC\_DIVISOR[7:0] PCD bit field to 0x8.

$$\text{PixelClock} = \frac{\text{LogicClock}}{8} = 6 \text{ Mhz} \quad \text{dss-ucE015}$$

Table 15-92 describes the registers to be configured for the display panel configuration step and the use case values.

**Table 15-92. Registers Print for Display Panel Configuration**

Register Name	Address	Value	Value Description
DISPC_CONTROL	0x4805 0440	0x0001 8108	See Section 15.6.5.4.5.1, Display Controller Configuration, for more details.
DISPC_SIZE_LCD	0x4805 047C	0x00EF 013F	QVGA display: 320 * 240
DISPC_CONFIG	0x4805 0444	0x0000 0004	Disable the palette
DISPC_TIMING_H	0x4805 0464	0x03B0 0801	Program horizontal timings
DISPC_TIMING_V	0x4805 0468	0x0050 0100	Program vertical timings
DISPC_POL_FREQ	0x4805 046C	0x0000 0000	Program the HSYNC and VSYNC signals for QVGA LCD panel
DISPC_DIVISOR	0x4805 0470	0x0002 0008	Set the divisors to program the PCLK frequency at 6 MHz.

#### 15.6.5.4.6 LCD Enable

The LCD enable step is composed of the following stages:

1. To enable the video1 layer, set the DSS.DISPC\_VID1\_ATTRIBUTES[0] VIDENABLE bit to 1. The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled.
2. To enable the display controller output, set the DSS.DISPC\_CONTROL[0] LCDENABLE bit to 1.
3. To account for all DISPC configuration done, set the DSS.DISPC\_CONTROL[5] GOLCD bit to 1 to indicate that all shadow registers of the video1 pipeline connected to the LCD output are latched by the hardware. The hardware can now update the internal registers at the VFP start period and the image displayed on the panel.

Table 15-93 describes the registers to be configured for the LCD enable step and the use case values.

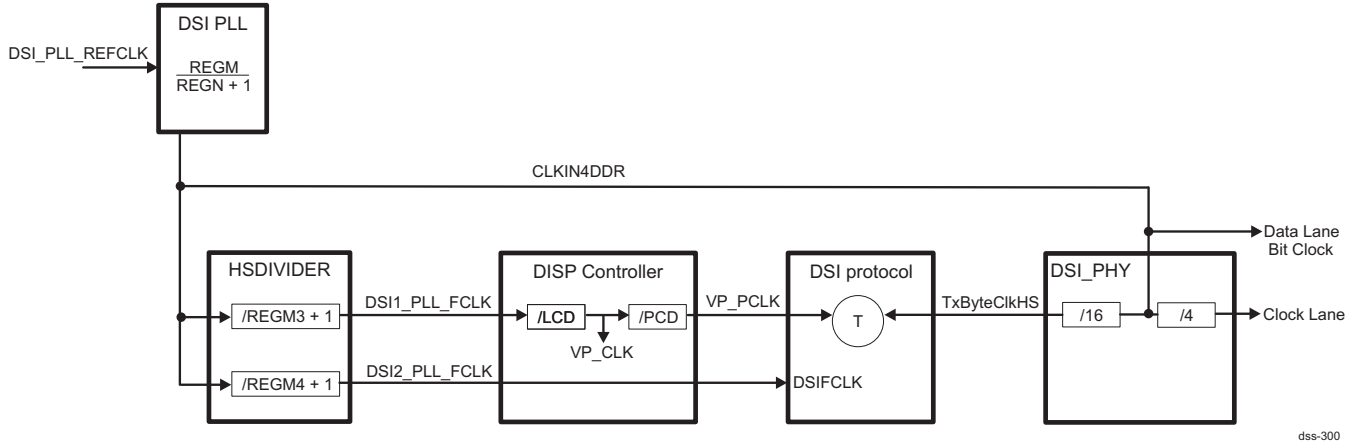

**Table 15-93. Registers Print for LCD Enable**

Register Name	Address	Value	Value Description
DISPC_CONTROL	0x4805 0440	0x0001 8129	Set DISPC_CONTROL[0] LCDENABLE and DISPC_CONTROL[5] GOLCD bits to 1.
DISPC_VID1_ATTRIBUTES	0x4805 04CC	0x0000 83F7	Enable the DISPC_VID1_ATTRIBUTES[0] VIDENABLE.

### 15.6.6 How to Configure the DSI PLL in Video Mode

Figure 15-176 shows a global overview of the DSI clock tree when used in video mode.

Figure 15-176. DSI Clock Tree in Video Mode

The settings of the DSI PLL registers can be summarized by 4 equations.

**Equation 1**

$$N * T_{VP\_CLK} = T_L * T_{TxByteClkHS} \tag{15-18}$$

dss-301

where

$$T_L = HSA_{DSI} + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}$$

$$HSA_{DSI} = 4 / NDL$$

N is an integer

NDL: Number of data lane

WC: Word count or payload in bytes

dss-304

**Equation 2**

$$R = T_{TxByteClkHS} / T_{VP\_PCLK} \tag{15-19}$$

dss-302

To synchronize DISPC and DSI Protocol Engine, users should follow the ratio T between TxByteClkHS and VP\_PCLK as listed in Table 15-94.

Table 15-94. Ratio R

Number of data lanes	Pixel format	Ratio R
1	16-bits pixel	1/2
1	18-bits pixel	4/9
1	24-bits pixel	1/3
2	16-bits pixel	1
2	18-bits pixel	8/9
2	24-bits pixel	2/3

All cases are covered by:

$$F_{VP\_PCLK} * bits\_per\_pixel = F_{TxByteClkHS} * NDL * 8 \tag{15-20}$$

dss-310

**Equation 3**

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) * T_{TxByteClkHS}$$

dss-303  
(15-20)

**Equation 4**

$$HFP_{DSI} = ((HFP_{DISPC} * bits\_per\_pixel) / (NDL * 8)) - (2 / NDL)$$

dss-309  
(15-21)

**Example**

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888
- 1-data lane
- LCD size 480\*640 with  $HSA_{DISPC} = HFP_{DISPC} = HBP_{DISPC} = 20$ ,  $VSA_{DISPC} = VFP_{DISPC} = VBP_{DISPC} = 2$

**Step 1. Determine REGM and REGN**

To obtain correct stability, Fint should be kept between 0.75 MHz and 2.1 MHz. In this case, Fint is maintained at 2 MHz. For more information, refer to the DSI PLL programming model.

$$REGN = (F_{DSI\_PLL\_REFCLK} / F_{int}) - 1$$

$$REGN = 12$$

$$REGM = (REGN+1) * F_{CLKIN4DDR} / (2 * F_{DSI\_PLL\_REFCLK})$$

$$REGM = 150$$

dss-318

Where DSS2\_ALWON\_FCLK= 26 MHz is used as a reference clock for  $F_{DSI\_PLL\_REFCLK}$

**Step 2. Determine VP\_PCLK and TxByteClkHS clocks.**

TxByteClkHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP\_PCLK frequency is equal to 12,5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{VP\_PCLK} / (HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * (VSA_{DISPC} + VFP_{DISPC} + LPP + VBP_{DISPC})$$

$$\text{Frame rate} = 12,5 \text{ MHz} / (540) * (646)$$

$$\text{Frame rate} = 35,83 \text{ frame/sec}$$

dss-323

**Step 3. Determine LCD, PCD and REGM3**

$$T_{CLKIN4DDR} = T_{TxByteClkHS} / 16 = T_{VP\_PCLK} / ((REGM3 + 1) * LCD * PCD)$$

$$((REGM3 + 1) * LCD * PCD) = 16 * 3$$

dss-315

If LCD and PCD are set to 1 and 3 respectively, REGM3 is equal to 15.

**Step 4. Verify N as integer**

Firstly, TL must be determined

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} / T_{TxByteClkHS} = T_L = 1620$$

dss-316

From **Equation 1**,

$$N * T_{VP\_CLK} = T_L * T_{TxByteClkHS}$$

$$N = T_{TxByteClkHS} * T_L / T_{VP\_CLK} = T_L / R$$

$$N = 4860$$

dss-322

N is an integer.

**Step 5. Determine HFP and HBP of the DSI protocol engine**

From **Equation 3**,

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} / T_{TxByteClkHS} - (4/NDL + (WC + 6)/NDL) = HFP_{DSI} + HBP_{DSI}$$

$$HFP_{DSI} + HBP_{DSI} = 170$$

dss-317

From **Equation 4**,

$$HFP_{DSI} = ((HFP_{DISPC} * \text{bits\_per\_pixel}) / (NDL * 8)) - (2 / NDL)$$

$$HFP_{DSI} = 58$$

$$HBP_{DSI} = 170 - 58 = 112$$

dss-321

### 15.6.7 DSI Video Mode Using the DISPC Video Port

This section details the basic programming model of video mode using the DISPC video port.

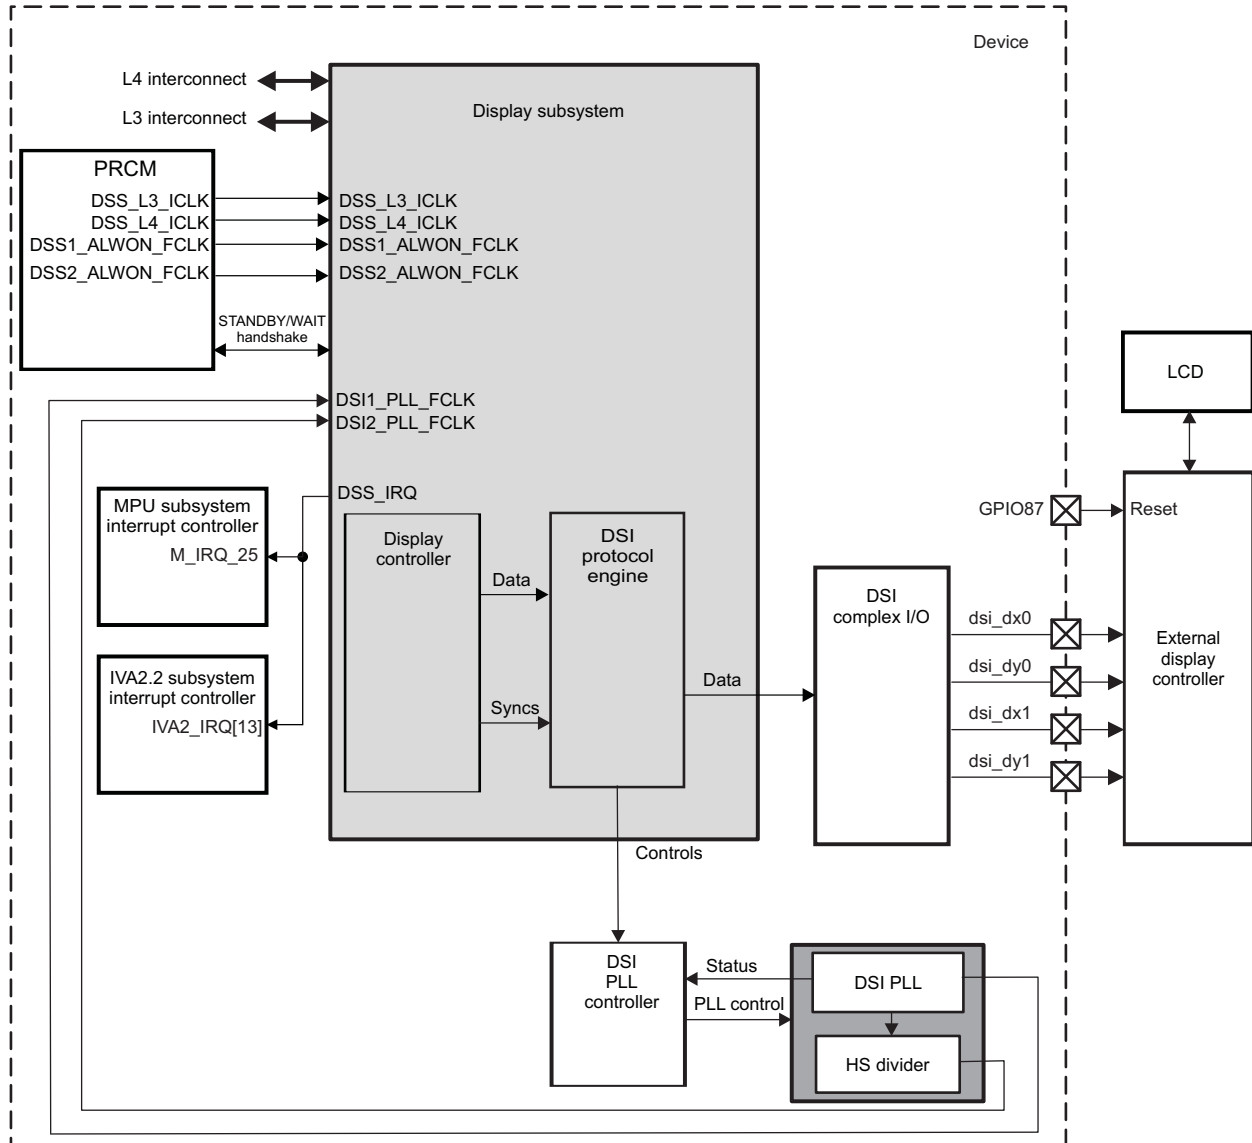

The DSI interface is connected to an external MIPI display controller and the following parameters are used:

- 1 data lane:  $NDL = 1$
- Clock lane at 150 MHz (DSI\_DDR\_CLK)
- LCD size is  $640 \times 480$ :
  - 480 pixels per line (PPL)
  - 680 lines per panel (LPP)
- Display controller input format: YUV
- Display controller output format: RGB888, that is 24 bits per pixel (BPP)
- Word Count:  $WC = 3 \times PPL$
- $DSS2\_ALWON\_FLCK=26$  MHz is used as a reference clock for DSI PLL
- Virtual channel 0 (VC0) is used for video mode.
- Interleaving is not used.
- It is assumed that all modules used in these programming models are in after-POR state.

[Figure 15-177](#) is an overview of the connections in the display subsystem.

Figure 15-177. Overview

dss-330

The steps listed in [Table 15-95](#) are described in the following sections.

Table 15-95. Main Steps

Steps	Section
Configure DSS clocks	<a href="#">Section 15.6.7.1, Display Subsystem Clock Configuration</a>
Configure the DSI and DSI PLL	<a href="#">Section 15.6.7.2, Configure DSI, DSI PLL and Complex I/O</a>
Configure the external MIPI display controller	<a href="#">Section 15.6.7.3, Initialization of the External MIPI Display Controller</a>
Configure the DISPC	<a href="#">Section 15.6.7.4, Configure the DISPC</a>
Enable video mode using the DISPC video port	<a href="#">Section 15.6.7.5, Enable Video Mode Using the DISPC Video Port</a>

The programming model must be followed in the order of the following sections.

### 15.6.7.1 Display Subsystem Clock Configuration

Table 15-96 lists the steps required to enable the clocks.

**Table 15-96. PRCM Registers**

Steps	Registers	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[31:0]	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[31:0]	0x0
Automatic transition between active and inactive are disabled.	CM_CLKSTCTRL_DSS[31:0]	0x0
Enable DSS1, DSS2 and TV clock (DSS1_ALWON_FCLK, DSS2_ALWON_FCLK and TV_CLK). TV_CLK is only need for correct Reset.	CM_FCLKEN_DSS[31:0]	0x7
Enable the subsystem interface clock (DSS_L3_ICLK and DSS_L4_ICLK).	CM_ICLKEN_DSS[31:0]	0x1

### 15.6.7.2 Configure DSI, DSI PLL and Complex I/O

#### 15.6.7.2.1 Reset DSI Modules

Table 15-97 lists the steps required to reset the DSI modules.

**Table 15-97. Resets**

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
OCP and functional clock are maintained during wakeup, smart idle, and reset DSI.	DSI_SYSCONFIG[31:0]	0x312
Wait until RESET_DONE ≠ 0.	DSI_SYSSTATUS[0] RESET_DONE	Read 0x1

#### 15.6.7.2.2 Set Up DSI DPLL

Table 15-98 lists the steps required to configure DSI PLL.

**Table 15-98. DSI PLL Configuration Registers**

Steps	Registers	Value
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CTRL	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	Read 0x2
See the calculation following this table.	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
See the calculation following this table.	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
See the calculation following this table.	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
See calculation following this table.	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Enable PLLStopMode.	DSI_PLL_CONFIGURATION1[0]	0x1
The DSI protocol engine clock divider, DSS clock divider, CLKIN4DDR, and PLL reference clock are enabled. PLL internal reference frequency is between 1.75 and 2.1MHz.	DSI_PLL_CONFIGURATION2[31:0]	0x5600E
Manual mode	DSI_PLL_CONTROL[31:0]	0x0

**Table 15-98. DSI PLL Configuration Registers (continued)**

Steps	Registers	Value
Request PLL locking sequence.	<a href="#">DSI_PLL_GO[0]</a> <a href="#">DSI_PLL_GO</a>	0x1
Read until <a href="#">DSI_PLL_GO</a> = 0	<a href="#">DSI_PLL_GO[0]</a> <a href="#">DSI_PLL_GO</a>	Read 0x0
PLL is locked.	<a href="#">DSI_PLL_STATUS[1]</a> <a href="#">DSI_PLL_LOCK</a>	Read 0x1
Turn on PLL and HSDIVIDER; the DSI functional clock > 30-MHz sync is rising/rising; the DSIStopClk signal is automatically asserted/deasserted; the L3_ICLK clock to the DSI complex I/O is not gated; and LPCLKDIVISOR = 8	<a href="#">DSI_CLK_CTRL[31:0]</a>	0x8024 4008

1. Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR} / \text{FDSI\_PLL\_REFCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

dss-E126

2. Determine LCD, PCD, and REGM3:

Calculate the divider value for DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC\_LCD} \times \text{DISPC\_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

3. Calculate N Divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI\_PLL\_REFCLK} / \text{FINT}) - 1$$

$$\text{FDSI\_PLL\_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

4. Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI\_PLL\_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

### 15.6.7.2.3 Switch to DSI PLL Clock Source

Select the DSI\_PLL1 clock as the DISPC functional clock, and select the DSI\_PLL2 clock as the DSI functional clock: Set [DSS\\_CONTROL](#) to 0x3.

### 15.6.7.2.4 Set Up DSI Protocol Engine

#### 15.6.7.2.4.1 Set Up DSI Control Registers

[Table 15-99](#) lists the steps to set up the DSI control registers. [Table 15-100](#) lists the steps to set up the DSI complex I/O registers.

**Table 15-99. DSI Control Registers**

Steps	Registers	Value
Enable SYNCLOST event.	<a href="#">DSI_IRQENABLE[31:0]</a>	0x4 0000
Set PACKET_SENT_IRQ_EN.	<a href="#">DSI_VC0_IRQENABLE[31:0]</a>	0x4

**Table 15-99. DSI Control Registers (continued)**

Steps	Registers	Value
While the HSYNC START pulse is detected, the associated short packet HSYNC START is generated.	<a href="#">DSI_CTRL[17]</a> VP_HSYNC_START	0x1
While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	<a href="#">DSI_CTRL[15]</a> VP_VSYNC_START	0x1
Set the trigger reset mode to <i>immediate</i> .	<a href="#">DSI_CTRL[14]</a> TRIGGER_RESET_MODE	0x1
Activate two line buffers.	<a href="#">DSI_CTRL[13:12]</a> LINE_BUFFER	0x2
HSYNC signal on the video port is active high.	<a href="#">DSI_CTRL[10]</a> VP_HSYNC_POL	0x1

#### 15.6.7.2.4.2 Configure DSI Timing and Virtual Channels

[Table 15-101](#) lists the steps to configure DSI timing and the virtual channels.

**Table 15-101. DSI Timing Registers**

Steps	Registers	Value
STOP_STATE_COUNTER_IO = 0x999	<a href="#">DSI_TIMING1[31:0]</a>	0x0000 0999
HS_TX_TO_X8, HS_TX_TO_COUNTER = 0x0FD2, LP_RX_TO_X16, LP_RX_TO_COUNTER = 0x00CD	<a href="#">DSI_TIMING2[31:0]</a>	0x2FD2 40CD
(HSA<<24) (HFP<<12) HBP	<a href="#">DSI_VM_TIMING1[31:0]</a>	0x0000 700A
(WINDOW_SYNC<<24) (VSA<<16) (DSI_VFP<<8) VBP	<a href="#">DSI_VM_TIMING2[31:0]</a>	0x0401 0101
(TL<<16) DSI_VACT	<a href="#">DSI_VM_TIMING3[31:0]</a>	0x05BB 0280

**Table 15-101. DSI Timing Registers (continued)**

Steps	Registers	Value
(ENTER_HS_MODE_LATENCY<<16) EXIT_HS_MODE_LATENCY	DSI_VM_TIMING7[31:0]	0x0000 C000A
DDR_CLK_PRE<<8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
HS speed, ECC generation for the Transmit, Enable CheckSum generation for the Payload.	DSI_VC0_CTRL[31:0]	0x2080 0390

- Freq TxByteClkHS :

$$FHSB = FCLKIN4DDR / 16$$

$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC\_LCD * DISPC\_PCD)$$

$$FVP = FCLKIN4DDR / (RegM3 + 1)$$

dss-E130

- Length of the line in video mode in Nb of byte clock cycles (TxByteClkHS):

$$TL = FHSB / FVPP \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

$$TL1f = (BPP / (8 \times NDL)) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

dss-E131

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC\_HSA + DISPC\_HBP + PPL + DISPC\_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP / THSB) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + (WC + 6) / NDL)$$

$$HBPplusHFP = (FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + WC + 6) / NDL$$

$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)) - ((HS + WC + 6) / NDL)$$

$$HFP = (DISPC\_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$

$$HBP = HBPplusHFP - HFP$$

dss-E132

### 15.6.7.2.5 Configure DSI\_PHY

For the calculation of DSI\_PHY timing, see [Table 15-102](#). See [Section 15.4.3.2](#), *Clock Requirements*, for details on timing calculation.

**Table 15-102. Calculate DSI\_PHY Timing**

Steps	Registers	Value
See <a href="#">Section 15.4.3.2</a>	DSI_PHY_CFG0[31:24] THS_PREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_CFG0[7:0] THS_EXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_CFG0[15:8] THS_TRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_CFG2[7:0] TCLK_PREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_CFG1[7:0] TCLK_ZERO	ceil(260 ns/DDR clock period)
	DSI_PHY_CFG1[15:0] TCLK_TRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_CFG1[22:16] TLPX_HALF	ceil(26.5 ns/DDR clock period)

---

**Note:** Keep Reserved bits at reset value in the DSI\_PHY\_CFG1 and DSI\_PHY\_CFG2 registers.

---

### 15.6.7.2.6 Drive Stop State

Table 15-103 lists the steps to Drive Stop State.

**Table 15-103. Drive Stop State**

Steps	Registers	Value
Force TX stop mode	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	Read 0x0

### 15.6.7.3 Initialization of the External MIPI Display Controller

1. Wait for the external MIPI display controller initialization after power up.  
In this example, the external MIPI display controller is reset using GPIO 87.
2. Configure the external MIPI display controller.

### 15.6.7.4 Configure the DISPC

#### 15.6.7.4.1 Reset DISPC

Table 15-104 lists the step sequence to reset the DISPC.

**Table 15-104. Reset DISPC**

Steps	Registers	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
DISPC is reset.	DISPC_SYSCONFIG[0] RESETDONE	Read 0x1
No standby: MStandby is never asserted.	DISPC_SYSCONFIG [13:12] MIDDLEMODE	0x1
Disable idle mode.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all interrupts.	DISPC_IRQENABLE[31:0]	0x0

#### 15.6.7.4.2 Configure DISPC Timing, Window, and Color

Table 15-105 lists the steps to configure the DISPC registers. Table 15-106 lists the steps to configure the color space coefficient registers.

Table 15-107 lists the steps to configure DISPC\_CONTROL.

**Table 15-105. Configure DISPC Registers**

Steps	Registers	Value
Set horizontal timings.	DISPC_TIMING_H	$(HBP - 1 \ll 20) \mid (HFP - 1 \ll 8) \mid HSA - 1$
Set vertical timing.	DISPC_TIMING_V	$(HBP - 1 \ll 20) \mid (HFP - 1 \ll 8) \mid HSA - 1$
Set LCD – PCD display controller and pixel clock divisor.	DISPC_DIVISOR	$LDC = \%1 \text{ PXLCLK} = \%4$
Set the size of the LCD – 1.	DISPC_SIZE_LCD	$(LPP - 1 + DSI\_VFP) \ll 16 \mid (PPL - 1)$
Set default RGB value when there is no data.	DISPC_DEFAULT_COLOR0	0xFF

**Table 15-105. Configure DISPC Registers (continued)**

Steps	Registers	Value
Set video FIFO height and low threshold.	DISPC_VID1_FIFO_THRESHOLD	0xfc00c0
Set the X Y location of the upper left pixel (0 = 0) to the upper left corner.	DISPC_VID1_POSITION	0x0
Set size of the window.	DISPC_VID1_SIZE	(LPP – 1) <<16 (PPL – 1)
Set the size of the picture.	DISPC_VID1_PICTURE_SIZE	(LPP – 1) <<16 (PPL – 1)
Set the input address picture.	DISPC_VID1_BA0	0x–

**Table 15-106. Configure Color Space Coefficient Registers**

Comments	Registers	Value
RCR and RY coefficients	DISPC_VID1_CONV_COEF0	0X0199012A
GY and RCB coefficients	DISPC_VID1_CONV_COEF1	0X012A0000
GCB and GCR coefficients	DISPC_VID1_CONV_COEF2	0X079C0730
BCR and BY coefficients	DISPC_VID1_CONV_COEF3	0X0000012A
BCB coefficient	DISPC_VID1_CONV_COEF4	0X00000205

**Table 15-107. Configure DISPC\_CONTROL**

Comments	Registers	Value
Enable pixel clock free-running.	<a href="#">DISPC_CONTROL[27]</a> PCLKFREEENABLE	0x1
I/O pad mode selection: Bypass	<a href="#">DISPC_CONTROL[16]</a> GPOUT1	0x1
I/O pad mode selection: Bypass	<a href="#">DISPC_CONTROL[15]</a> GPOUT0	0x1
Normal mode selected	<a href="#">DISPC_CONTROL[11]</a> STALLMODE	0x0
3 for RGB888	<a href="#">DISPC_CONTROL[9:8]</a> TFTDATALINES	0x3
The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update completes.	<a href="#">DISPC_CONTROL[5]</a> GOLCD	0x0
Active matrix display operation mode	<a href="#">DISPC_CONTROL[3]</a> STNTFT	0x1
LCD interface is disabled.	<a href="#">DISPC_CONTROL[0]</a> LCDENABLE	0x0

The input image is converted from UYVY into RGB (see [Table 15-108](#)) :

**Table 15-108. Configure DISPC\_VID1\_ATTRIBUTES**

Comments	Registers	Value
Row of VIDn will not be read twice.	DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
8 x 32-bit bursts	DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE	0x1
Full range selected: Y is not modified before the color space conversion.	DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE	0x1
Enable color space conversion CbYCr to RGB.	DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE	0x1
UYVY	DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT	0xB
Video disabled	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x0

### 15.6.7.5 Enable Video Mode Using the DISPC Video Port

[Table 15-109](#) lists the steps to enable DISPC to send frames continuously.

**Table 15-109. Enable DISPC**

Steps	Registers	Value
Set up long packet header	DSI_VC0_LONG_PACKET_HEADER[31:0]	0x0005 A03E
Enable VC0.	DSI_VC0_CTRL[1] VC_EN	0x1
Enable IF.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN ≠ 0.	DSI_CTRL[0] IF_EN	Read 0x0
Enable VID1.	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x1
Enable LCD interface.	DISPC_CONTROL[0] LCDENABLE	0x1
Enable GOLCD.	DISPC_CONTROL[5] GOLCD	0x1
Wait until GOLCD = 0.	DISPC_CONTROL[5] GOLCD	Read 0x0

### 15.6.8 DSI Command Mode Using the DISPC Video Port

This section presents some generic use cases and tips for setting the modules of the display subsystem.

#### 15.6.8.1 Display Subsystem Use Cases and Tips

This section explains the basic programming model of command mode using the DISPC video port.

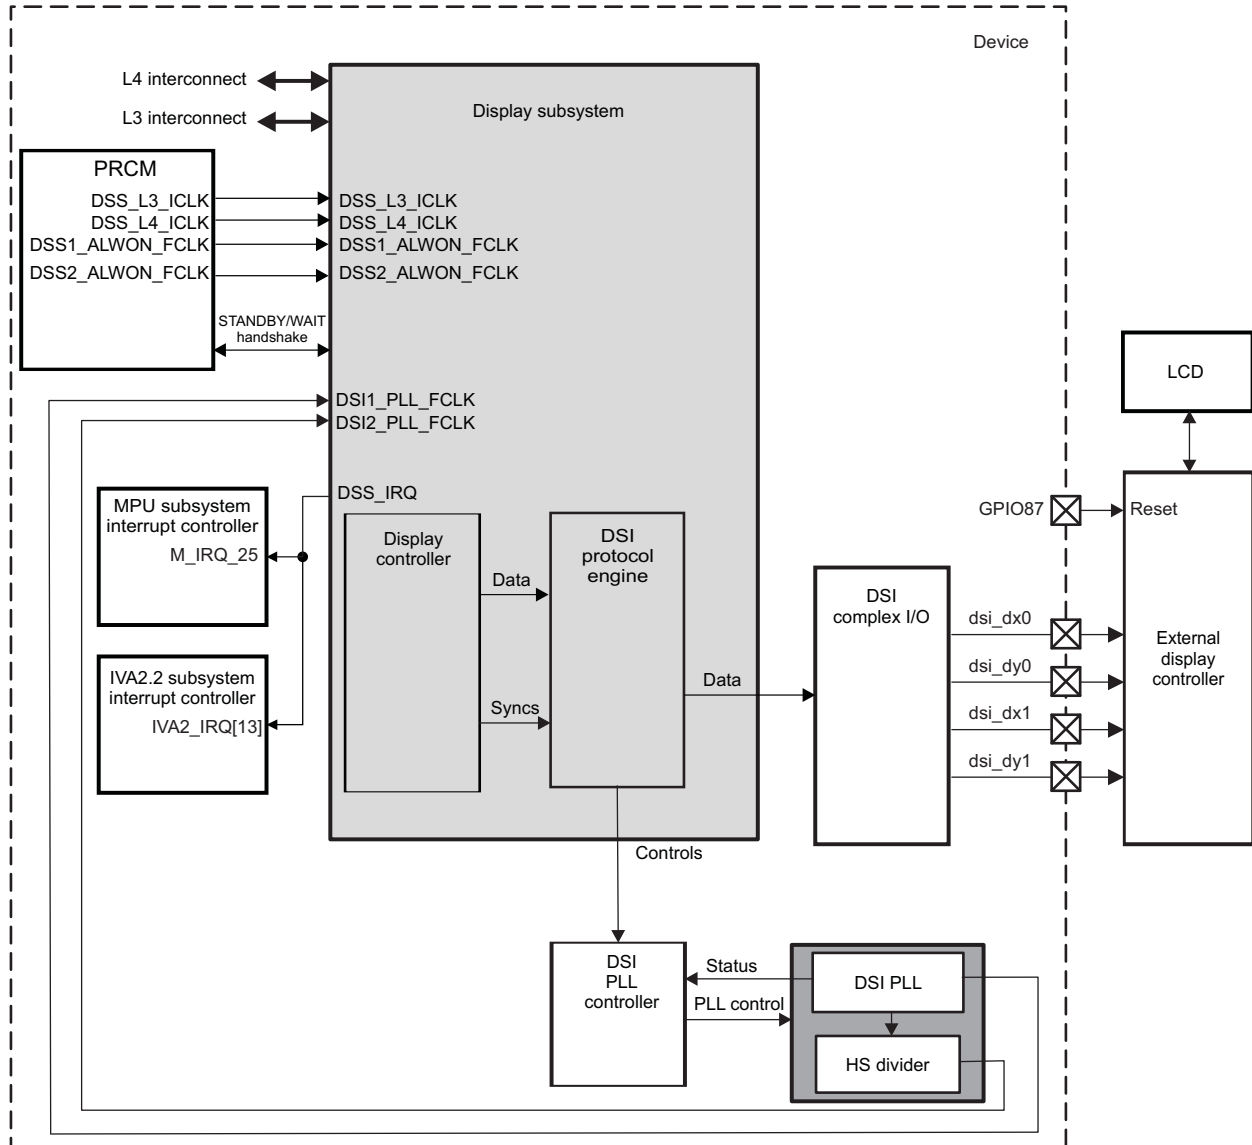

The DSI interface is connected to an external MIPI DISPC using the following parameters:

- One data lane: NDL = 1
- Clock lane at 150 MHz (DSI\_DDR\_CLK)
- LCD size is 640 × 480:
  - 480 PPL
  - 680 LPP
- DISPC input format: YUV
- DISPC output format: RGB888 (24 BPP)
- Word Count: WC = 3 × PPL
- DSS2\_ALWON\_FLCK = 26 MHz used as a reference clock for DSI PLL
- Virtual channel 1 (VC1) used for command mode to configure the external DISPC, and virtual channel 0 (VC0) used to send data
- Automatic TE used for synchronization
- Interleaving not used
- It is assumed that all modules used in these programming models are in after-POR state.

[Figure 15-178](#) is an overview of the connections in the display subsystem.

Figure 15-178. Overview

dss-330

Table 15-110 lists the steps of the main sequence and the sections that describe them.

Table 15-110. Main Sequence

Steps	Register/Bit Field/Programming Model
Configure DSS clocks.	<a href="#">Section 15.6.8.1.1, Configure DSS Clocks at the PRCM Module</a>
Configure the DSI protocol engine and DSI PLL.	<a href="#">Section 15.6.8.1.2, Configure DSI Protocol Engine, DSI PLL, and Complex I/O</a>
Configure the external MIPI display controller.	<a href="#">Section 15.6.8.1.3, Initialization of the External MIPI Display Controller</a>
Configure the DISPC.	<a href="#">Section 15.6.8.1.4, Configure the DISPC</a>
Enable command mode using the DISPC video port.	<a href="#">Section 15.6.8.1.5, Enable Command Mode Using the DISPC Video Port</a>
Send a frame data to LCD panel using automatic TE.	<a href="#">Section 15.6.8.1.6, Send Frame Data to LCD Panel Using Automatic TE</a>

The programming model must follow the step sequence.

### 15.6.8.1.1 Configure DSS Clocks at the PRCM Module

Table 15-111 lists the steps required to enable the clocks.

**Table 15-111. Configure DSS Clocks at the PRCM Module**

Steps	Register/Bit Field/Programming Model	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[0] AUTO_DSS	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[2:0] EN_IVA2, EN_MPU, EN_CORE	0x0
Disable automatic transition.	CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS	0x0
Enable the DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, and TV_CLK functional clocks. <sup>(1)</sup>	CM_FCLKEN_DSS[2:0] EN_TV, EN_DSS2, EN_DSS1	0x7
Enable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks.	CM_ICLKEN_DSS[0] EN_DSS	0x1

<sup>(1)</sup> TV\_CLK is required only for a correct reset.

### 15.6.8.1.2 Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Table 15-112 lists the steps to configure the DSI protocol engine, DSI PLL, and complex I/O and the sections that describe the sequence.

**Table 15-112. Configure DSI Protocol Engine, DSI PLL, and Complex I/O**

Steps	Register/Bit Field/Programming Model
Reset DSI modules.	<a href="#">Section 15.6.8.1.2.1, Reset DSI Modules</a>
Configure DSI DPLL.	<a href="#">Section 15.6.8.1.2.2, Configure DSI PLL</a>
Switch to DSI PLL clock source.	<a href="#">Section 15.6.8.1.2.3, Switch to DSI PLL Clock Source</a>
Configure DSI protocol engine.	<a href="#">Section 15.6.8.1.2.4, Configure DSI Protocol Engine</a>
Configure DSI_PHY.	<a href="#">Section 15.6.8.1.2.5, Configure DSI_PHY</a>
Drive stop state.	<a href="#">Section 15.6.8.1.2.6, Drive Stop State</a>

#### 15.6.8.1.2.1 Reset DSI Modules

Table 15-113 lists the steps required to reset the DSI modules.

**Table 15-113. Reset DSI Modules**

Steps	Register/Bit Field/Programming	Value
Clear DSI IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Maintain interface and functional clock during wakeup.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	0x3
Enable smart-idle for power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	0x2
Set DSI reset.	DSI_SYSCONFIG[1] SOFT_RESET	0x1
Wait until RESET_DONE = 1.	DSI_SYSSTATUS[0] RESET_DONE	

#### 15.6.8.1.2.2 Configure DSI PLL

Table 15-114 lists the steps required to configure the DSI PLL.

**Table 15-114. Configure DSI PLL**

Steps	Register/Bit Field/Programming	Value
Enable PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	
Set the REGM4 value (see <a href="#">Step 1</a> ).	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
Set the REGM3 value (see <a href="#">Step 2</a> ).	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
Set the REGN value (see <a href="#">Step 3</a> ).	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Set the REGM value (see <a href="#">Step 4</a> ).	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
Enable PLL STOPMODE.	DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	0x1
Set the PLL internal reference frequency range between 1.75 and 2.1 MHz.	DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL	0x7
Enable PLL reference clock control.	DSI_PLL_CONFIGURATION2[13] DSI_PLL_REFEN	0x1
Enable CLKIN4DDR control.	DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN	0x1
Enable DSS clock divider.	DSI_PLL_CONFIGURATION2[16] DSS_CLOCK_EN	0x1
Enable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] DSI_PROTO_CLOCK_EN	0x1
Enable DSI configuration update with DISPC_UPDATE_SYNC.	DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE	0x0
Start PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Wait until DSI_PLL_GO = 0.	DSI_PLL_GO[0] DSI_PLL_GO	
Check whether PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	0x1
Set the LP mode clock ratio.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	0x8
Set L3_ICLK clock to the DSI complex I/O to not gated.	DSI_CLK_CTRL[14] CIO_CLK_ICG	0x1
Enable the automatic assertion/deassertion of the DSISopClk signal.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	0x1
Specify that the DSI functional clock is higher than 30 MHz with a synchronization rising/rising.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	0x1
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2

1. Calculate the divider value for the DSI protocol engine clock source:

$$\begin{aligned} \text{RegM4} &= \text{FCLKIN4DDR} / \text{FDSI\_PLL\_REFCLK} - 1 \\ \text{FCLKIN4DDR} &= 4 \times \text{FCLKIN} \\ \text{RegM4} &= 5 \end{aligned}$$

dss-E126

2. Determine LCD, PCD, and REGM3:

Calculate the divider value for the DSS clock source: Same as Step 3.

$$\begin{aligned} \text{RegM3} &= ((\text{BPP} \times 2) / (\text{DISPC\_LCD} \times \text{DISPC\_PCD} \times \text{NDL})) - 1 \\ \text{RegM3} &= 15 \end{aligned}$$

dss-E127

3. Calculate N divider for PLL:

$$\begin{aligned} \text{FCLKIN4DDR} &= \text{FCLKIN} \times 4 \\ \text{RegN} &= (\text{FDSI\_PLL\_REFCLK} / \text{F Int}) - 1 \\ \text{FDSI\_PLL\_REFCLK} &= 26 \text{ MHz (system clock)} \\ \text{Fint} &= 2 \text{ MHz (reduce PLL lock time)} \\ \text{RegN} &= 12 \end{aligned}$$

dss-E128

4. Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI\_PLL\_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

### 15.6.8.1.2.3 Switch to DSI PLL Clock Source

Table 15-115 lists the sequence to switch the DSI and DISPC module clocks to DSI PLL clock source.

**Table 15-115. Switch to DSI PLL Clock Source**

Steps	Register/Bit Field/Programming	Value
Switch DISPC clock to DSI1_PLL_FCLK.	DSS_CONTROL[0] DISPC_CLK_SWITCH	0x1
Switch DSI clock to DSI2_PLL_FCLK.	DSS_CONTROL[1] DSI_CLK_SWITCH	0x1

### 15.6.8.1.2.4 Configure DSI Protocol Engine

#### 15.6.8.1.2.4.1 Set Up DSI Control Registers

Table 15-116 lists the steps required to set up the DSI control registers. Table 15-117 lists the steps to set up the DSI complex I/O registers.

**Table 15-116. DSI Control Registers**

Steps	Register/Bit Field/Programming	Value
Enable SYNCLOST event.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on VC1.	DSI_VC1_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Enable IRQ to indicate that packet has been sent on VC0.	DSI_VC0_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Set the trigger reset mode to <i>immediate</i> .	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate the two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
Set the size of the video port data bus to 24 bits (RGB 888).	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	0x1
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as sequential scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

**Table 15-117. DSI Complex I/O Registers**

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	0x2
Determine the position of data 1 lane.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	0x3
Turn on COMPLEXIO.	DSI_COMPLEXIO_CFG[28:27] PWR_CMD	0x1
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear all COMPLEXIO IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable all COMPLEXIO IRQs.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable interface.	DSI_CTRL[0] IF_EN	0x1
Disable interface.	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0.	DSI_CTRL[0] IF_EN	
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1

**Table 15-117. DSI Complex I/O Registers (continued)**

Steps	Register/Bit Field/Programming	Value
Check whether reset is complete.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	0x1
Check whether power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	0x1
Check whether reset is complete.	DSI_SYSTATUS[0] RESETDONE	0x1

#### 15.6.8.1.2.4.2 Configure DSI Timing and Virtual Channels

Table 15-118 lists the steps to configure DSI timing and the virtual channels.

**Table 15-118. DSI Timing Registers**

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x999
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x0
Disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x0
Clear turn-around timer settings.	DSI_TIMING1[30:16]	0x0000
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x0CD
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x0
Enable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x1
Determine the number of TxByteClkHS clock cycles for the HS RX timer.	DSI_TIMING2[12:0] HS_TX_TO_COUNTER	0xFD2
Disable the multiplication factor of 8 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[13] HS_TX_TO_X8	0x0
Enable the multiplication factor of 16 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[14] HS_TX_TO_X16	0x1
DDR_CLK_PRE<<8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
<b>Configuration of VC1</b>		
Enable the checksum generation for the transmit payload.	DSI_VC1_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC1_CTRL[8] ECC_TX_EN	0x1
Disable DMA request for TX FIFO.	DSI_VC1_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC1_CTRL[29:27] DMA_RX_REQ_NB	0x4
<b>Configuration of VC0</b>		
Selects source of data and enable VP_STALL.	DSI_VC0_CTRL[1] SOURCE	0x1
Enable the checksum generation for the transmit payload.	DSI_VC0_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC0_CTRL[8] ECC_TX_EN	0x1
Enable high-speed mode to send short and long packets to the peripheral.	DSI_VC0_CTRL[9] MODE_SPEED	0x1
Disable DMA request for TX FIFO.	DSI_VC0_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC0_CTRL[29:27] DMA_RX_REQ_NB	0x4

**Table 15-118. DSI Timing Registers (continued)**

Steps	Register/Bit Field/Programming	Value
Configuration TX and RX FIFO		
Set size of the RX FIFO allocated for VC1 to 32 x 33 bits.	DSI_RX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x1
Set size of the TX and TX FIFO allocated for VC1 to 96 x 33 bits.	DSI_TX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x3

- Freq HSBYTE\_CLK:

$$FHSB = FCLKIN4DDR / 16$$

$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC\_LCD * DISPC\_PCD)$$

$$FVP = FCLKIN4DDR / (RegM3 + 1)$$

dss-E130

- Length of the line in video mode in number of byte clock cycles (PPI clk):

$$TL = FHSB / FVPP \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

$$TL1f = (BPP / (8 \times NDL)) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

dss-E131

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC\_HSA + DISPC\_HBP + PPL + DISPC\_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP / THSB) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + (WC + 6) / NDL)$$

$$HBPplusHFP = (FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + WC + 6) / NDL$$

$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)) - ((HS + WC + 6) / NDL)$$

$$HFP = (DISPC\_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$

$$HBP = HBPplusHFP - HFP$$

dss-E132

#### 15.6.8.1.2.5 Configure DSI\_PHY Timing

Table 15-119 summarizes DSI\_PHY timing. For more details on timing calculation, see Section 15.4.3.2, *Clock Requirements*.

**Table 15-119. Configure DSI\_PHY Timing**

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 15.4.3.2, <i>Clock Requirements</i> .	DSI_PHY_CFG0[31:24] THS_PREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_CFG0[7:0] THS_EXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_CFG0[15:8] THS_TRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_CFG2[7:0] TCLK_PREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_CFG1[7:0] TCLK_ZERO	ceil(260 ns/DDR clock period)
	DSI_PHY_CFG1[15:0] TCLK_TRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_CFG1[22:16] TLPX_HALF	ceil(26.5 ns/DDR clock period)

**Note:** Keep Reserved bits at reset value in the DSI\_PHY\_CFG1 and DSI\_PHY\_CFG2 registers.

### 15.6.8.1.2.6 Drive Stop State

Table 15-120 lists the steps to drive the stop state.

**Table 15-120. Drive Stop State**

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0.	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	

### 15.6.8.1.3 Initialization of the External MIPI LCD Controller

Table 15-121 lists the steps to initialize the external MIPI LCD controller.

**Table 15-121. Initialization of the External MIPI LCD Controller**

Steps	Register/Bit Field/Programming	Value
Reset the MIPI LCD controller using GPIO87.	–	0x1
Wait until initialization of the external MIPI LCD controller is finished after power up.	–	–
Configure the external MIPI LCD controller.	–	–

### 15.6.8.1.4 Configure the DISPC

#### 15.6.8.1.4.1 Reset DISPC

Table 15-122 lists the steps to reset the DISPC.

**Table 15-122. Reset DISPC**

Steps	Register/Bit Field/Programming	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
Wait until RESETDONE = 1.	DISPC_SYSCONFIG[0] RESETDONE	
Disable master interface power management.	DISPC_SYSCONFIG [13:12] MIDDLEMODE	0x1
Disable slave interface power management.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all DISPC interrupts.	DISPC_IRQENABLE[31:0]	0x0

#### 15.6.8.1.4.2 Configure DISPC Timing, Window, and Color

Table 15-123 lists the steps to configure the DISPC registers. Table 15-106 lists the steps to configure the color space coefficient registers.

Table 15-124 lists the steps to configure DISPC\_CONTROL.

**Table 15-123. Configure DISPC Registers**

Steps	Register/Bit Field/Programming	Value
Configure LCD output		
Set the logic clock divisor (LCD).	DISPC_DIVISOR[23:16] LCD	0x1
Set the pixel clock divisor (PCD).	DISPC_DIVISOR[7:0] PCD	0x4
Set the number of lines on the LCD panel.	DISPC_SIZE_LCD[26:16] LPP	0x2A7
Set the number of PPL on the LCD panel.	DISPC_SIZE_LCD[10:0] PPL	0x1DF

**Table 15-123. Configure DISPC Registers (continued)**

Steps	Register/Bit Field/Programming	Value
Set solid background color.	DISPC_DEFAULT_COLOR0	0xFF
Configure VIDEO pipeline VID1.		
Set VID1 FIFO low threshold.	DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOWLOWTHRESHOLD	0x0C0
Set VID1 FIFO high threshold.	DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD	0xFC0
Set the X position of the VID1 window.	DISPC_VID1_POSITION[10:0] VIDPOSX	0x0
Set the Y position of the VID1 window.	DISPC_VID1_POSITION[26:16] VIDPOSY	0x0
Set the number of lines of the VID1 window.	DISPC_VID1_SIZE[26:16] VIDSIZEY	0x2A7
Set the number of pixels of the VID1 window.	DISPC_VID1_SIZE[10:0] VIDSIZEX	0x1DF
Define the base address of the VID1 frame buffer.	DISPC_VID1_BA0	0x–

**Table 15-124. Configure DISPC\_CONTROL**

Comments	Register/Bit Field/Programming	Value
Enable pixel clock free-running.	DISPC_CONTROL[27] PCLKFREEENABLE	0x1
Disable RFBI.	DISPC_CONTROL[16] GPOUT1	0x1
	DISPC_CONTROL[15] GPOUT0	0x1
Enable the stall mode.	DISPC_CONTROL[11] STALLMODE	0x1
Select size of DATALINES.	DISPC_CONTROL[9:8] TFTDATALINES	0x3
Select active matrix display operation mode.	DISPC_CONTROL[3] STNTFT	0x1
Disable LCD output interface.	DISPC_CONTROL[0] LCDENABLE	0x0
Update the internal DISPC registers.	DISPC_CONTROL[5] GOLCD	0x1

### 15.6.8.1.5 Enable Command Mode Using DISPC Video Port

Table 15-125 lists the steps to enable DISPC to send frames continuously. Two bus turn-arounds (BTA) must be generated (see the MIPI DSI specification for details):

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

**Table 15-125. Enable Command Mode and Automatic TE**

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue code.	DSI_CTRL[25] DCS_CMD_CODE	0x0
Enable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_CTRL[24] DCS_CMD_ENABLE	0x1
Enable VC1.	DSI_VC1_CTRL[0] VC_EN	0x1
Enable VC0.	DSI_VC0_CTRL[0] VC_EN	0x1
Enable the interface.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN = 1.	DSI_CTRL[0] IF_EN	
Send the sequence to receive the TE trigger from the peripheral. In this use case, code 0x35 + 1 parameter VC = 0, data type = 0x15, DCS write + 1 parameter.	DSI_VC1_SHORT_PACKET_HEADER[31:0] HEADER	0x0000 3515
Wait until PACKET_SENT_IRQ = 1.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	
Write 1 to clear PACKET_SENT_IRQ.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	0x1

### 15.6.8.1.6 Send Frame Data to LCD Panel Using Automatic TE

Table 15-126 summarizes the steps to send a frame data to the LCD panel using automatic TE.

**Table 15-126. Send Frame Data to LCD Panel Using Automatic TE**

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	DISPC_CONTROL[0] LCDENABLE	0x1
Specify the number of bytes to send. When DCS insertions is used, word count (WC) must include this one DCS byte.	DSI_VC0_TE[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header. Send 0x39 DCS long write/write_LUT command packet used to send larger blocks of data to a display module that implements a DCS.	DSI_VC0_LONG_PACKET_HEADER[31:0] HEADER	(WC+1) << 8 + 0x39
Enable TE control.	DSI_VC0_TE[30] TE_EN	0x1
Wait until RX FIFO is empty, RX_FIFO_NOT_EMPTY = 0.	DSI_VC1_CTRL[20] RX_FIFO_NOT_EMPTY	0x0
Wait until TX FIFO is not full. TX_FIFO_FULL = 0.	DSI_VC1_CTRL[16] TX_FIFO_FULL	0x0
Enable first BTA to give bus possession to the display module.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Enable second BTA to get the TE trigger.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Wait until transfer is complete.	DSI_VC0_TE[30] TE_EN	Read 0x0

## 15.7 Display Subsystem Register Manual

### CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access..
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI\_VCn\_LONG\_PACKET\_HEADER and DSS.DSI\_VCn\_SHORT\_PACKET\_HEADER registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI\_VCn\_LONG\_PACKET\_PAYLOAD register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

Table 15-127 summarizes the display subsystem instance.

**Table 15-127. Instance Summary**

Module Name	Base Address	Size
DSI Protocol Engine	0x4804 FC00	512 bytes
DSI_PHY	0x4804 FE00	64 bytes
DSI PLL Controller	0x4804 FF00	32 bytes
Display Subsystem	0x4805 0000	512 bytes
Display Controller	0x4805 0400	1K byte
Display Controller VID1	0x4805 0400	1K byte
Display Controller VID2	0x4805 0400	1K byte
RFBI	0x4805 0800	256 bytes
Video Encoder	0x4805 0C00	256 bytes

### 15.7.1 Display Subsystem Register Mapping Summary

Table 15-128 through Table 15-132 summarize the display subsystem register mapping.

**Table 15-128. Display Subsystem Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
DSS_REVISIONNUMBER	R	32	0x000	0x4805 0000

## 15.7.2 Register Descriptions

### 15.7.2.1 Display Subsystem and SDI Registers

**Table 15-136. DSS\_REVISIONNUMBER**

<b>Address Offset</b>	0x000	
<b>Physical address</b>	0x4805 0000	<b>Instance</b> DISS
<b>Description</b>	This register contains the display subsystem revision number.	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																REV															

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Read returns 0.	R	0x000000
7:0	REV	Revision number [7:4] Major revision [3:0] Minor revision	R	TI internal data

**Table 15-137. Register Call Summary for Register DSS\_REVISIONNUMBER**

- Display Subsystem Register Manual

**Table 15-138. DSS\_SYSCONFIG**

<b>Address Offset</b>	0x010	
<b>Physical address</b>	0x4805 0010	<b>Instance</b> DISS
<b>Description</b>	This register controls the various parameters of the interconnect interface.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																Reserved	Reserved	SOFTRESET	AUTOIDLE												

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Write 0s for future compatibility. Reads return zero.	RW	0x00000000
4:3	Reserved	Reserved. Keep at reset value.	RW	0x0
2	Reserved	Write 0s for future compatibility . Reads return zero.	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0.  0x0: Normal mode 0x1: The module is reset	RW	0
0	AUTOIDLE	Enable power management capability  0x0: OCP clock is free-running 0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity	RW	1

**Table 15-154. DISPC\_SYSCONFIG**

<b>Address Offset</b>	0x010	
<b>Physical address</b>	0x4805 0410	<b>Instance</b> DISC
<b>Description</b>	This register allows the control of various parameters of the interconnect interface.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																MIDLEMODE	Reserved	CLOCKACTIVITY	Reserved	SIDLEMODE	ENWAKEUP	SOFTRESET	AUTOIDLE								

Bits	Field Name	Description	Type	Reset
31:14	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000000
13:12	MIDLEMODE	Master interface power management, standby/waitcontrol 0x0: Force standby. MStandby is asserted only when the module is disabled. 0x1: No standby: MStandby is never asserted.	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x2: Smart Standby. MStandby is asserted based on the internal activity of the module.		
		0x3: Reserved		
11:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
9:8	CLOCKACTIVITY	Clock activity during wakeup mode period	RW	0x0
		0x0: interface and functional clocks can be switched off.		
		0x1: Functional clocks can be switched off and interface clocks are maintained during wakeup period.		
		0x2: Interface clocks can be switched off and functional clocks are maintained during wakeup period.		
		0x3: Interface and functional clocks are maintained during wakeup period.		
7:5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
4:3	SIDLEMODE	Slave interface power management, idle req/ack control	RW	0x0
		0x0: Force idle. An idle request is acknowledged unconditionally.		
		0x1: No idle. An idle request is never acknowledged.		
		0x2: Smart idle. Idle request is acknowledged based on the internal activity of the module.		
		0x3: Reserved		
2	ENWAKEUP	Wakeup feature control	RW	0
		0x0: Wakeup is disabled.		
		0x1: Wakeup is enabled.		
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0
		0x0: Normal mode		
		0x1: The module is reset.		
0	AUTOIDLE	Internal interface clock gating strategy	RW	1
		0x0: Interface clock is free-running.		
		0x1: Automatic L3 and L4 interface clock gating strategy is applied based on interface activity.

27	PCKFREEENABLE	Pixel clock free-running enabled/disabled 0x0: Clock disabled 0x1: Clock enabled	RW	0																											
26:25	TDMUNUSEDBITS	State of unused bits (TDM mode only) WR: VFP 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved	RW	0x0																											
24:23	TDMCYCLEFORMAT	Cycle format (TDM mode only) WR: VFP 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels	RW	0x0																											
22:21	TDMPARALLELMODE	Output Interface width (TDM mode only) WR: VFP 0x0: 8-bit parallel output interface selected 0x1: 9-bit parallel output interface selected	RW	0x0																											

Bits	Field Name	Description	Type	Reset
		0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected		
20	TDMENABLE	Enable the multiple cycle format (TDM mode used only for Active Matrix mode with the RFBI enable bit off). WR: VFP 0x0: TDM disabled 0x1: TDM enabled	RW	0
19:17	HT	Hold Time for digital output WR: EVSYNC Encoded value (from 0 to 7) holds time for digital output. The data will be held for (HT + 1) external digital clock periods.	RW	0x0
16	GPOUT1	General Purpose Output Signal 0x0: The GPout1 is reset. 0x1: The GPout1 is set.	RW	0
15	GPOUT0	General Purpose Output Signal 0x0: The GPout0 is reset. 0x1: The GPout0 is set.	RW	0
14	GPIN1	General Purpose Input Signal WR: VFP Read 0x0: The GPin1 has been reset. Read 0x1: The GPin1 has been set.	R	0
13	GPIN0	General Purpose Input Signal WR: VFP Read 0x0: The GPin0 has been reset. Read 0x1: The GPin0 has been set.	R	0
12	OVERLAYOPTIMIZATION	Overlay Optimization (available when graphics format is NOT is 1-, 2, and 4-BPP) WR: VFP or EVSYNC 0x0: Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows. 0x1: Graphics data below video1 window not fetched from memory.	RW	0
11	STALLMODE	Stall mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI and DSI command modes.	RW	0
10	Reserved	Reserved for non-GP devices	RW	0
9:8	TFTDATALINES	Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0

Bits	Field Name	Description	Type	Reset
7	STDITHERENABLE	Spatial temporal dithering enable WR: VFP  0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0
6	GODIGITAL	Digital GO Command  0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC.	RW	0
5	GOLCD	LCD GO Command  0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.	RW	0
4	M8B	Mono 8-bit mode WR: VFP  0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode). 0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode).	RW	0
3	STNTFT	LCD display type WR: VFP  0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled. 0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/Color WR: VFP  0x0: Color operation enabled (Passive Matrix mode only) 0x1: Monochrome operation enabled (Passive Matrix mode only)	RW	0
1	DIGITALENABLE	Digital enable  0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: Digital output enabled	RW	0
0	LCDENABLE	LCD enable  0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

Bits	Field Name	Description	Type	Reset
31: 20	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x00000
19	TVALPHABLENDER ENABLE	Selects the alpha blender (TV output)	RW	0
		0x0: Alpha blender is disabled.		

Bits	Field Name	Description	Type	Reset
		0x1: The alpha blender is enabled.		
18	LCDALPHABLENDER ENABLE	Selects the alpha blender (LCD output)	RW	0
		0x0: Alpha blender is disabled.		
		0x1: The alpha blender is enabled.		
17	FIFOFILLING	Controls if the FIFO are refilled only when the LOW threshold is reached or if all FIFO are refilled when at least one of them reaches the LOW threshold.	RW	0
		0x0: Each FIFO is refilled when it reaches LOW threshold.		
		0x1: All FIFOs are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs should be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again).		
16	FIFOHANDCHECK	Controls the handshake between FIFO and RFBI STALL to prevent from underflow. The bit should be set to 0 when the module is not in STALL mode.	RW	0
		0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information to provide data to the RFBI module.		
		0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information to provide data to the RFBI module only when it does not generated FIFO underflow.		
15	CPR	Color phase rotation control wr: VFP	RW	0
		0x0: Color phase rotation disabled		
		0x1: Color phase rotation enabled		
14	FIFOMERGE	FIFO merge control wr: EVSYNC or VFP	RW	0
		0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline.		
		0x1: FIFO merge enabled All the FIFOS are merged into a single one to be used by the single active pipeline.		
13	TCKDIGSELECTION	Transparency color key selection (digital output) wr: EVSYNC	RW	0
		0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode		
		0x1: Video source transparency color key selected in normal mode		
12	TCKDIGENABLE	Transparency color key enabled (digital output) wr: EVSYNC	RW	0
		0x0: Disable the transparency color key for digital output		
		0x1: Enable the transparency color key for digital output		
11	TCKLCDSELECTION	Transparency color key selection (LCD output) WR: VFP	RW	0
		0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode		
		0x1: Video source transparency color key selected in normal mode		
10	TCKLCDENABLE	Transparency color key enabled (LCD output) WR: VFP *	RW	0
		0x0: Disable the transparency color key for the LCD		
		0x1: Enable the transparency color key for the LCD		
9	FUNCGATED	Functional clocks gated enabled WR: immediate	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled		
8	ACBIASGATED	ACBias Gated Enabled WR: VFP 0x0: AcBias Gated Disabled 0x1: AcBias Gated Enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled WR: VFP 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled	RW	0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0
4	PIXELDATAGATED	Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0
3	PALETTEGAMMATABL	Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0
2:1	LOADMODE	Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. ( <a href="#">DISPC_GFX_ATTRIBUTES</a> . GfxEnable has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W).	RW	0x0
0	PIXELGATED	Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)	RW	0

Bits	Field Name	Description	Type	Reset
31: 25	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
24	VIDSELFREFRESH	Enables the self refresh of the video window from its own FIFO only.  0x0: The video pipeline accesses the interconnect to fetch data from the system memory  0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO	RW	0
23	VIDARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them.  0x0: The video pipeline is one of the normal priority pipeline.  0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	VIDLINEBUFFER SPLIT	Video vertical line buffer split  0x0: Vertical line buffers are not split.  0x1: Vertical line buffers are split into two.	RW	0
21	VIDVERTICALTAPS	Video vertical resize tap number  0x0: Three taps are used for the vertical filtering logic. The other two taps are not used.  0x1: Five taps are used for the vertical filtering logic.	RW	0
20	VIDDMAOPTI MIZATION	Video optimization in case of  0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory).  0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory).	RW	0
19	VIDFIFOPRELOAD	Video preload value  0x0: H/W prefetches pixels up to the preload value defined in the preload register.  0x1: H/W prefetches pixels up to the high threshold value.	RW	0
18	VIDROWREPEAT ENABLE	Video Row Repeat (YUV case only when rotating 90 or 270-degree)  0x0: Row of VIDn won't be read twice.  0x1: The Row data are fetched twice to extract both the Y components	RW	0
17	VIDENDIANNESS	Video Endianness  0x0: Little endian operation is selected.  0x1: Big endian operation is selected.	RW	0
16	VIDCHANNELOUT	Video Channel Out configuration wr: Immediate  0x0: LCD output selected  0x1: 24 bit output selected	RW	0
15:14	VIDBURSTSIZE	Video DMA Burst Size  0x0: 4x32bit bursts  0x1: 8x32bit bursts  0x2: 16x32bit bursts  0x3: Reserved	RW	0x0
13:12	VIDROTATION	Video Rotation Flag  0x0: No rotation or VidFormat is RGB	RW	0x0

Bits	Field Name	Description	Type	Reset			
11	VIDFULLRANGE	0x1: Rotation by 90 degrees	RW	0			
		0x2: Rotation by 180 degrees					
		0x3: Rotation by 270 degrees					
		VidFullRange					
		0x0: Limited range selected: 16 subtracted from Y before color space conversion					
		0x1: Full range selected: Y is not modified before the color space conversion					
10	VIDREPLICATION ENABLE	VidReplicationEnable	RW	0			
		0x0: Disable Video replication logic					
		0x1: Enable Video replication logic					
9	VIDCOLORCONV ENABLE	VidColorConvEnable	RW	0			
		0x0: Disable Color Space Conversion CbYCr to RGB					
		0x1: Enable Color Space Conversion CbYCr to RGB					
8	VIDVRESIZECONF	Video Vertical Resize Configuration	RW	0			
		0x0: Up-sampling selected					
		0x1: Down-sampling selected

**Table 15-260. RFBI\_SYSCONFIG**

<b>Address Offset</b>	0x10	
<b>Physical address</b>	0x4805 0810	<b>Instance</b> RFBI
<b>Description</b>	This register allows control of various parameters of the interconnect interface.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																Reserved	Reserved	SIDLEMODE	Reserved	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:7	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
6	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 00: Force-idle: Idle request is acknowledged unconditionally. 01: No idle: An idle request is never acknowledged 10: Smart idle: Idle request is acknowledged based on the internal activity of the module. 11: Reserved	RW	0x0
2	Reserved	Write 0s for future compatibility Read returns 0	RW	0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Software reset Sets this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0: Normal mode 1: The module is reset	RW	0
0	AUTOIDLE	Internal clock gating strategy (interconnectL4 and display controller clock) 0: Interconnect L4 clock and display controller clock are free-running. 1: Automatic clock gating strategy is applied for the interconnect L4 clock and display controller clock, based on the interconnect interface and internal activity.	RW	1

**Table 15-264. RFBI\_CONTROL**

<b>Address Offset</b>	0x40	<b>Instance</b>	RFBI
<b>Physical address</b>	0x4805 0840		
<b>Description</b>	The control register allows configuration of the RFBI module.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SMART_DMA_REQ	DISABLE_DMA_REQ	HIGHTHRESHOLD	ITE	CONFIGSELECT	BYPASSMODE	ENABLE									

Bits	Field Name	Description	Type	Reset
31: 9	Reserved	Write 0s for future compatibility Read returns 0	RW	0x00000000
8	SMART_DMA_REQ	Smart DMA request  0x0: The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if Mldlreq is high in smart idle/no-idle mode and the entire burst gets error responses from the module.  0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlreq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.	RW	0x0
7	DISABLE_DMA_REQ	Disable DMA request  0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register.  0x1: The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests.	RW	0x0
6:5	HIGHTHRESHOLD	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to <a href="#">RFBI_DATA</a> are sent using system DMA.  0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide	RW	0x0
4	ITE	Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.	RW	0
3:2	CONFIGSELECT	Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used)	RW	0x0

Bits	Field Name	Description	Type	Reset
1	BYPASSMODE	Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected	RW	1
0	ENABLE	Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module	RW	0

<b>Address Offset</b>	0x5C		<b>Instance</b>	VENC
<b>Physical address</b>	0x4805 0C5C			
<b>Description</b>	VENC L21 & WC_CTL registers			
<b>Type</b>	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																INV	EVEN_ODD_EN		LINE						Reserved				L21EN		

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Reserved. Read returns 0s.	RW	0x0000
15	INV	WSS inverter 0x0: No effect	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Invert WSS data		
14:13	EVEN_ODD_EN	This bit controls the WSS encoding. 0x0: WSS encoding OFF 0x1: Enables encoding in 1 <sup>st</sup> field (odd field) 0x2: Enables encoding in 2 <sup>nd</sup> field (even field) 0x3: Enables encoding in both fields	RW	0x0
12:8	LINE	Selects the line where WSS data are encoded. The LINE[4:0] bit field value depends on the video standard: PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line 0x16 + 1 = 0x17 (23rd line). NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line 0x10 + 4 = 0x14 (20th line).	RW	0x14
7:2	Reserved	Reserved. Read returns 0s.	RW	0x00
1:0	L21EN	Those bits controls the Line21 closed caption encoding according to the mode. 0x0: Line21 encoding OFF 0x1: Enables encoding in 1st field (odd field) 0x2: Enables encoding in 2d field (even field) 0x3: Enables encoding in both fields	RW	0x0

<b>Address Offset</b>	0x0000 00C4	
<b>Physical Address</b>	0x4805 0CC4	<b>Instance</b> VENC
<b>Description</b>	Output channel control register Also contains some test control features	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LUMA_TEST								RESERVED								CHROMA_SOURCE	COMPOSITE_SOURCE	LUMA_SOURCE	TEST_MODE	VIDEO_INVERT	CHROMA_ENABLE	COMPOSITE_ENABLE	LUMA_ENABLE

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved. Read returns 0s.	RW	0x00
25:16	LUMA_TEST	In test mode, DAC 1 input value (if s-video video mode is selected)	RW	0x000
15:8	RESERVED	Reserved. Read returns 0s.	RW	0x00
7	CHROMA_SOURCE	Source of chroma video data in test mode  0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16]  0x1: Chroma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
6	COMPOSITE_SOURCE	Source of composite video data in test mode  0x0: Composite test data comes from internal register OUTPUT_TEST[9:0]  0x1: Composite test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
5	LUMA_SOURCE	Source of luminance video data in test mode  0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16]  0x1: Luma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
4	TEST_MODE	This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits  0x0: Video outputs are in normal operation  0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port.	RW	0x0
3	VIDEO_INVERT	Controls the video output polarity. This may be used to correct for inversion in an external video amplifier.  0x0: Video outputs are inverted  0x1: Video outputs are normal polarity	RW	0x1
2	CHROMA_ENABLE	Enable the Chrominance output channel  0x0: Chroma output is disabled  0x1: Chroma output is enabled	RW	0x0
1	COMPOSITE_ENABLE	Enable the Composite output channel  0x0: Composite output is disabled  0x1: Composite output is enabled	RW	0x0
0	LUMA_ENABLE	Enable the Luminance output channel  0x0: Luma output is disabled  0x1: Luma output is enabled	RW	0x0

### 15.7.2.5 DSI Protocol Engine Registers

**Table 15-382. DSI\_REVISION**

<b>Address Offset</b>	0x0000 0000	
<b>Physical Address</b>	0x4804 FC00	<b>Instance</b> DSI_PROTOCOL_ENGINE
<b>Description</b>	MODULE REVISION This register contains the IP revision code in binary coded digital. For example, we have: 0x01 = revision 0.1 and 0x21 = revision 2.1	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision	R	TI internal data

**Table 15-383. Register Call Summary for Register DSI\_REVISION**

Display Subsystem Register Manual

**Table 15-384. DSI\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	0x4804 FC10	<b>Instance</b> DSI_PROTOCOL_ENGINE
<b>Description</b>	SYSTEM CONFIGURATION REGISTER This register is the system configuration register.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED				CLOCKACTIVITY	RESERVED		SIDLEMODE	ENWAKEUP	SOFT_RESET	AUTO_IDLE					

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
13:10	RESERVED	Write 0s for future compatibility.	RW	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: Interface and Functional clocks can be switched off 0x1: Functional clocks can be switched off and Interface clocks are maintained during wake up period 0x2: Interface clocks can be switched off and Functional clocks are maintained during wake up period 0x3: Interface and Functional clocks are maintained during wake up period	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved	RW	0x2
2	ENWAKEUP	Wake-up mode enable bit 0x0: Wakeup is disabled. 0x1: Wakeup is enabled,	RW	0x0
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied based on the module interface activity.	RW	0x1

**Table 15-390. DSI\_IRQENABLE**

<b>Address Offset</b>	0x0000 001C	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Physical Address</b>	0x4804 FC1C		
<b>Description</b>	INTERRUPT ENABLE REGISTER - This register associates one bit for each VC to enable/disable each VC individually.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED											TA_TO_IRQ_EN	LDO_POWER_GOOD_IRQ_EN	SYNC_LOST_IRQ_EN	ACK_TRIGGER_IRQ_EN	TE_TRIGGER_IRQ_EN	LP_RX_TO_IRQ_EN	HS_TX_TO_IRQ_EN	RESERVED	RESERVED	RESERVED	PLL_RECAL_IRQ_EN	PLL_UNLOCK_IRQ_EN	PLL_LOCK_IRQ_EN	RESERVED	RESYNCHRONIZATION_IRQ_EN	WAKEUP_IRQ_EN	RESERVED				

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
20	TA_TO_IRQ_EN	Turn-around Time out. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

Bits	Field Name	Description	Type	Reset
19	LDO_POWER_GOOD_IRQ_EN	Transition of the status signal LDOPWRGOOD from the DSI_PHY indicating a state change for the supply VDDALDODSIPLL from up to down or down to up.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
18	SYNC_LOST_IRQ_EN	Synchronization with Video port is lost (Video mode only)  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
17	ACK_TRIGGER_IRQ_EN	Acknowledge trigger  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
16	TE_TRIGGER_IRQ_EN	Tearing Effect trigger  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
15	LP_RX_TO_IRQ_EN	Interrupt for Low Power Rx Time out.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
14	HS_TX_TO_IRQ_EN	Interrupt for high-speed Tx Time out.  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:11	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
9	PLL_RECAL_IRQ_EN	PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module)  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
8	PLL_UNLOCK_IRQ_EN	PLL un-lock event (deassertion of lock signal from the DSI PLL Control module)  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
7	PLL_LOCK_IRQ_EN	PLL lock event (assertion of lock signal from the DSI PLL Control module)  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
5	RESYNCHRONIZATION_IRQ_EN	Resynchronization  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	WAKEUP_IRQ_EN	Wakeup  0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

**Table 15-392. DSI\_CTRL**

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Physical Address</b>	0x4804 FC40		
<b>Description</b>	GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register should not be modified dynamically (except IF_EN bit field).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED								RGB565_ORDER	DCS_CMD_CODE	DCS_CMD_ENABLE	HSA_BLANKING_MODE	HBP_BLANKING_MODE	HFP_BLANKING_MODE	BLANKING_MODE	EOT_ENABLE	VP_HSYNC_END	VP_HSYNC_START	VP_VSYNC_END	VP_VSYNC_START	TRIGGER_RESET_MODE	LINE_BUFFER	VP_VSYNC_POL	VP_HSYNC_POL	VP_DE_POL	VP_CLK_POL	VP_DATA_BUS_WIDTH	TRIGGER_RESET	VP_CLK_RATIO	TX_FIFO_ARBITRATION	ECC_RX_EN	CS_RX_EN	IF_EN

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
26	RGB565_ORDER	Byte order for RBG565 command mode from video port 0x0: Unused 0x1: Byte order as for video mode	RW	0
25	DCS_CMD_CODE	DCS command code value to insert between header and video port data when enabled by DCS_CMD_ENABLE 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted.	RW	0
24	DCS_CMD_ENABLE	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is not inserted when command mode traffic is coming from the Video Port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0x0

Bits	Field Name	Description	Type	Reset
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0x0
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0x0
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) regardless of the packets present in the TX FIFO ready to be sent	RW	0x0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS to LP transitions	RW	0
18	VP_HSYNC_END	HSYNC end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0x0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0x0
16	VP_VSYNC_END	VSYNC end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0x0
15	VP_VSYNC_START	VSYNC start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	RW	0x0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is VC using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0x0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0

Bits	Field Name	Description	Type	Reset
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0x0
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0x0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0x0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	0x1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.	RW	0x0
4	VP_CLK_RATIO	This bit indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0x0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the VC pending ready requests in the TX FIFO 0x0: Round-Robin Scheme is used 0x1: Sequential Scheme is used	RW	0x0
2	ECC_RX_EN	Enables the ECC check for the received header (short and long packets for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IF_EN	<p>Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register).</p> <p>It is not possible to change the bit fields in the <a href="#">DSI_CTRL</a> register, except IF_EN when it is enabled. All the other registers can be changed except the ones that require <a href="#">DSI_VCn_CTRL[0]</a> VC_EN to be equal to 0 to be modified.</p> <p>0x0: The interface is disabled. If one of the VC uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other VCs in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested).</p> <p>0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).</p>	RW	0x0

**Table 15-394. DSI\_COMPLEXIO\_CFG1**

<b>Address Offset</b>	0x0000 0048	
<b>Physical Address</b>	0x4804 FC48	<b>Instance</b> DSI_PROTOCOL_ENGINE
<b>Description</b>	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHADOWING	GOBIT	RESET_DONE	PWR_CMD	PWR_STATUS	RESERVED	RESERVED	RESERVED	LDO_POWER_GOOD_STATE	USE_LDO_EXTERNAL	RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	DATA2_POL	DATA2_POSITION	DATA1_POL	DATA1_POSITION	CLOCK_POL	CLOCK_POSITION										

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration. 0x0: Disabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done only when the GO bit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active.	RW	0x0
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case users decide to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the GObit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit must be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using TxByteClkHS from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ultralow-power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in ultralow-power state	R	0x0
24:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	LDO_POWER_GOOD_STATE	Indicates the state of the signal LDOPWRGOOD. VDDALDODSIPLL: 1.2-V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSI_PHY.  0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up	R	0x0
20	USE_LDO_EXTERNAL	Select the external LDO for the DSI_PHY. 0x0: DSI_PHY internal LDO is used. 0x1: External LDO is used. DSI_PHY LDO is tri-stated.	RW	0x0
19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
14:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1 (line 1). 0x2: Data lane 2 is at the position 2 (line 2). 0x3: Data lane 2 is at the position 3 (line 3). Other values: reserved	RW	0x0
7	DATA1_POL	+/- differential pin order of DATA lane 1 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. 0x1: Data lane 1 is at the position 1 (line 1). 0x2: Data lane 1 is at the position 2 (line 2). 0x3: Data lane 1 is at the position 3 (line 3). Other values: reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1 (line 1). 0x2: Clock lane is at the position 2 (line 2). 0x3: Clock lane is at the position 3 (line 3). Other values: reserved	RW	0x0

<b>Address Offset</b>	0x0000 0054	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Physical Address</b>	0x4804 FC54		
<b>Description</b>	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL_PWR_CMD		PLL_PWR_STATUS		RESERVED								LP_RX_SYNCHRO_ENABLE	LP_CLK_ENABLE	HS_MANUAL_STOP_CTRL	HS_AUTO_STOP_ENABLE	LP_CLK_NULL_PACKET_SIZE	LP_CLK_NULL_PACKET_ENABLE	CIO_CLK_ICG	DDR_CLK_ALWAYS_ON	LP_CLK_DIVISOR											

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	Command for power control of the DSI PLL Control module 0x0: Command to change to OFF state 0x1: Command to change to ON state for PLL only (HSDIVISER is OFF) 0x2: Command to change to ON state for both PLL and HSDIVISER 0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	RW	0x0
29:28	PLL_PWR_STATUS	Status of the power control of the DSI PLL Control module 0x0: DSI PLL Control module in OFF state 0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF) 0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER 0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	R	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
21	LP_RX_SYNCHRO_ENABLE	Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.	RW	0x0
20	LP_CLK_ENABLE	Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] bit field is not used and does not have to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] bit field is used and must be programmed.	RW	0x0
19	HS_MANUAL_STOP_CTRL	In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit field allows manual control of the assertion/deassertion of the signal DSISStopClk by users. 0x0: DSISStopClk deassertion unconditionally. 0x1: DSISStopClk assertion unconditionally.	RW	0x0
18	HS_AUTO_STOP_ENABLE	Enables the automatic assertion/deassertion of DSISStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled.	RW	0x0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0x0
14	CIO_CLK_ICG	Controls the signal for gating the L3_ICLK clock provided to the complex I/O 0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated. 0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated.	RW	0x0

Bits	Field Name	Description	Type	Reset
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted.  0x0: Disabled. The DDR clock is only provided when HS packets are sent.  0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LP mode).	RW	0x0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191 (the value 0 is invalid). The output frequency must be in the range between 20 MHz and 32 kHz.	RW	0x0001

**Table 15-402. DSI\_TIMING1**

<b>Address Offset</b>	0x0000 0058	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Physical Address</b>	0x4804 FC58		
<b>Description</b>	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while <a href="#">DSI_CTRL.IF_EN</a> is set to 1. It is used to indicate the number of DSI_FCLK clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER													FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO												

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer  0x0: Turn-around counter is disabled.  0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0

Bits	Field Name	Description	Type	Reset
30	TA_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field  0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x  0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	0x1
29	TA_TO_X8	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field  0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x  0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.	RW	0x1FFF
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal  0x0: Deassertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit to stop the assertion of the ForceTXStopMode signal prior to the completion of the period.  0x1: Assertion of ForceTxStopMode	RW	0x0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field  0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x  0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 16x	RW	0x1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field  0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x  0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 4x	RW	0x1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

<b>Address Offset</b>	0x0000 0064	
<b>Physical Address</b>	0x4804 FC64	<b>Instance</b> DSI_PROTOCOL_ENGINE
<b>Description</b>	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	
<b>Type</b>	RW	
	31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
	RESERVED	WINDOW_SYNC VSA VFP VBP

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:24	WINDOW_SYNC	Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronization on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15.	RW	0x0
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

<b>Address Offset</b>	0x0000 006C																														
<b>Physical Address</b>	0x4804 FC6C								<b>Instance</b>	DSI_PROTOCOL_ENGINE																					
<b>Description</b>	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register should not be modified while <a href="#">DSI_CTRL.IF_EN</a> is set to 1.																														
<b>Type</b>	RW																														
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DDR_CLK_PRE								DDR_CLK_POST															
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>														<b>Type</b>	<b>Reset</b>														
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.														RW	0x0000														
15:8	DDR_CLK_PRE	Indicates the number of TxByteClkHS cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if <a href="#">DSI_CLK_CTRL[13]</a> DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.														RW	0x01														
7:0	DDR_CLK_POST	Indicates the number of TxByteClkHS cycles after the deassertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if <a href="#">DSI_CLK_CTRL[13]</a> DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.														RW	0x01

<b>Description</b>	Defines the maximum number of bytes of Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENTER_HS_MODE_LATENCY																EXIT_HS_MODE_LATENCY															

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000
15:0	EXIT_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TxByteClkHS clock cycles from deassertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Reset</b>
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29:27	DMA_RX_REQ_NB	Selection of the use of the DMA request (associated to the RX FIFO)  0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
26:24	DMA_RX_THRESHOLD	Defines the threshold value for the DMA request (associated to the RX FIFO)  0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
23:21	DMA_TX_REQ_NB	Selection of the use of the DMA request (associated to the TX FIFO)  0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
20	RX_FIFO_NOT_EMPTY	FIFO status in command mode. Otherwise, this bit can be ignored.  0x0: The RX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO)  0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored.  0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full	R	0x0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration.  0x0: No pending operations for this VC 0x1: Pending operations for this VC	R	0x0
14	PP_BUSY	Line buffer busy status.  0x0: Software is permitted to write a new header for VP command mode traffic. 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0

Bits	Field Name	Description	Type	Reset
13:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	MODE_SPEED	Selection of the mode. This bit is ignored by hardware when video mode is selected.  0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral.  0x1: High speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0x0
8	ECC_TX_EN	Enables the ECC generation for the transmit header (short and long packets).  0x0: Disabled 0x1: Enabled	RW	0x0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only).  0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW.	RW	0x0
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode allows users to define for which packets, the turn around is required for example getting acknowledge from the peripheral.  0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, must not be used).  0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.	RW	0x0
5	TX_FIFO_NOT_EMPTY	FIFO status  0x0: The TX FIFO is empty (the FIFO does not contain any data for the VC)  0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
4	MODE	Selection of the mode  0x0: Command mode. 0x1: Video mode.	RW	0x0
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission.  0x0: Disabled 0x1: Enabled	RW	0x0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission.  0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
1	SOURCE	<p>Selection of the source between L4 interconnect slave port and video port. This bit is ignored by hardware when video mode is selected.</p> <p>0x0: All the data are provided by the L4 interconnect slave port. Any transfer on the video port is ignored for this VC.</p> <p>0x1: If MODE=VIDEO_MODE, any data received on the video port (pixels and enabled synchronization events using <a href="#">DSI_CTRL[17]</a> VP_HSYNC_START, <a href="#">DSI_CTRL[18]</a> VP_HSYNC_END, <a href="#">DSI_CTRL[15]</a> VP_VSYNC_START, <a href="#">DSI_CTRL[16]</a> VP_VSYNC_END,) are sent on the VC (only one VC can be associated with the video port, the software must ensure that no more than one VC is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the L4 interconnect slave port.</p>	RW	0x0
0	VC_EN	<p>Enables the VC.</p> <p>0x0: Disabled. The VC must be disabled for any register change in the DSI_VCn_XXX registers the corresponding VC ID.</p> <p>0x1: Enabled. No change is allowed to the VC registers (except for setting the bit fields/registers: <a href="#">DSI_VCn_CTRL[6]</a> BTA_EN, <a href="#">DSI_VCn_TE[15:0]</a> TE_SIZE, <a href="#">DSI_VCn_TE[31]</a> TE_START, <a href="#">DSI_VCn_LONG_XXX</a>, <a href="#">DSI_VCn_SHORT_XXX</a>, <a href="#">DSI_VCn_IRQXXX</a> registers).</p>	RW	0x0

**Table 15-436. DSI\_VCn\_TE**

<b>Address Offset</b>	0x0000 0104+ (n* 0x20)	<b>Index</b>	n = 0 to 3
<b>Physical Address</b>	0x4804 FD04+ (n* 0x20)	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Description</b>	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TE_START	TE_EN	RESERVED						TE_SIZE																							

Bits	Field Name	Description	Type	Reset
31	TE_START	Manual control of the start of the transfer. Users can use the TE interrupt to determine that the TE trigger has been received before setting the TE_START bit field. It is not mandatory to use the TE interrupt.  0x0: Indicates the end of the transfer. The bit can be used to cancel the transfer if not already started. The FIFO must be flushed by software to ensure it contains no remaining data.  0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer completes. It is reset by hardware when the transfer completes.	RW	0
30	TE_EN	Tearing effect control  0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The interruption is used to know when the TE trigger is received. The hardware resets the bit field when the transfer completes(TE_SIZE=0).  0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event.	RW	0
29:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
23:0	TE_SIZE	Defines the number of bytes (payload data excluding the check-sum) to be sent. Users must perform the write into the <a href="#">DSI_VCn_LONG_PACKET_HEADER</a> register before sending data from the <a href="#">DSI_VCn_LONG_PACKET_PAYLOAD</a> register. The register value is decremented for every byte of the DSI link that is sent. At the end of the transfer (TE_SIZE = 0), the TE_EN bit field is reset by hardware. The DMA_request is asserted when the trigger is received in order to receive data in the TX FIFO. It must not be used until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

**Table 15-444. DSI\_VCn\_IRQSTATUS**

<b>Address Offset</b>	0x0000 0118+ (n* 0x20)	<b>Index</b>	n = 0 to 3
<b>Physical Address</b>	0x4804 FD18+ (n* 0x20)	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Description</b>	INTERRUPT STATUS REGISTER - Virtual channel This register regroups all the events related to the VC.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																PP_BUSY_CHANGE_IRQ	FIFO_TX_UDF_IRQ	ECC_NO_CORRECTION_IRQ	BTA_IRQ	FIFO_RX_OVF_IRQ	FIFO_TX_OVF_IRQ	PACKET_SENT_IRQ	ECC_CORRECTION_IRQ	CS_IRQ							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
8	PP_BUSY_CHANGE_IRQ	Video port ping-pong buffer busy status.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0
7	FIFO_TX_UDF_IRQ	FIFO underflow status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO).  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	ECC_NO_CORRECTION_IRQ	ECC error status (short and long packets). No correction of the header because of more than 1-bit error.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
5	BTA_IRQ	Virtual channel - BTA status.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
4	FIFO_RX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the DSI link for the VC has overflowed.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
3	FIFO_TX_OVF_IRQ	FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has overflowed.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
2	PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
1	ECC_CORRECTION_IRQ	Virtual channel - ECC has been used to do the correction of the only 1-bit error status (short and long packet only).  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
0	CS_IRQ	Virtual channel - Check-Sum mismatch status.  0x0: READS: Event is false. WRITES: Status bit unchanged.  0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

<b>Address Offset</b>	0x0000 011C+ (n* 0x20)	<b>Index</b>	n = 0 to 3
<b>Physical Address</b>	0x4804 FD1C + (n* 0x20)	<b>Instance</b>	DSI_PROTOCOL_ENGINE
<b>Description</b>	INTERRUPT ENABLE REGISTER - Virtual channel This register regroups all the events related to VC.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							PP_BUSY_CHANGE_IRQ_EN	FIFO_TX_UDF_IRQ_EN	ECC_NO_CORRECTION_IRQ_EN	BTA_IRQ_EN	FIFO_RX_OVF_IRQ_EN	FIFO_TX_OVF_IRQ_EN	PACKET_SENT_IRQ_EN	ECC_CORRECTION_IRQ_EN	CS_IRQ_EN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
8	PP_BUSY_CHANGE_IRQ_EN	Video port ping-pong buffer busy. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0
7	FIFO_TX_UDF_IRQ_EN	FIFO underflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	ECC_NO_CORRECTION_IRQ_EN	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
5	BTA_IRQ_EN	Virtual channel -Bus turn around reception 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	FIFO_RX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the DSI link for the VC has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3	FIFO_TX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has overflowed. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
2	PACKET_SENT_IRQ_EN	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
1	ECC_CORRECTION_IRQ_EN	Virtual channel - ECC has been used to correct the only 1-bit error (short and long packet). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
0	CS_IRQ_EN	Virtual channel - Check-Sum of the payload mismatch detection 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

## 16.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose timers (GP timers), 2 watchdog timers (WDTs), a 32-kHz synchronized timer. Figure 16-1 shows the counters in the device in a high-level block diagram.

**Figure 16-1. Timers**

PU108-027

The 2 WDTs are clocked with 32-kHz clocks. The 32-kHz synchronized timer, which is reset only at power up, provides the operating system with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

## 16.2 General-Purpose Timers

### 16.2.1 GP Timers Overview

The device has 11 GP timers: GPTIMER1 through GPTIMER11.

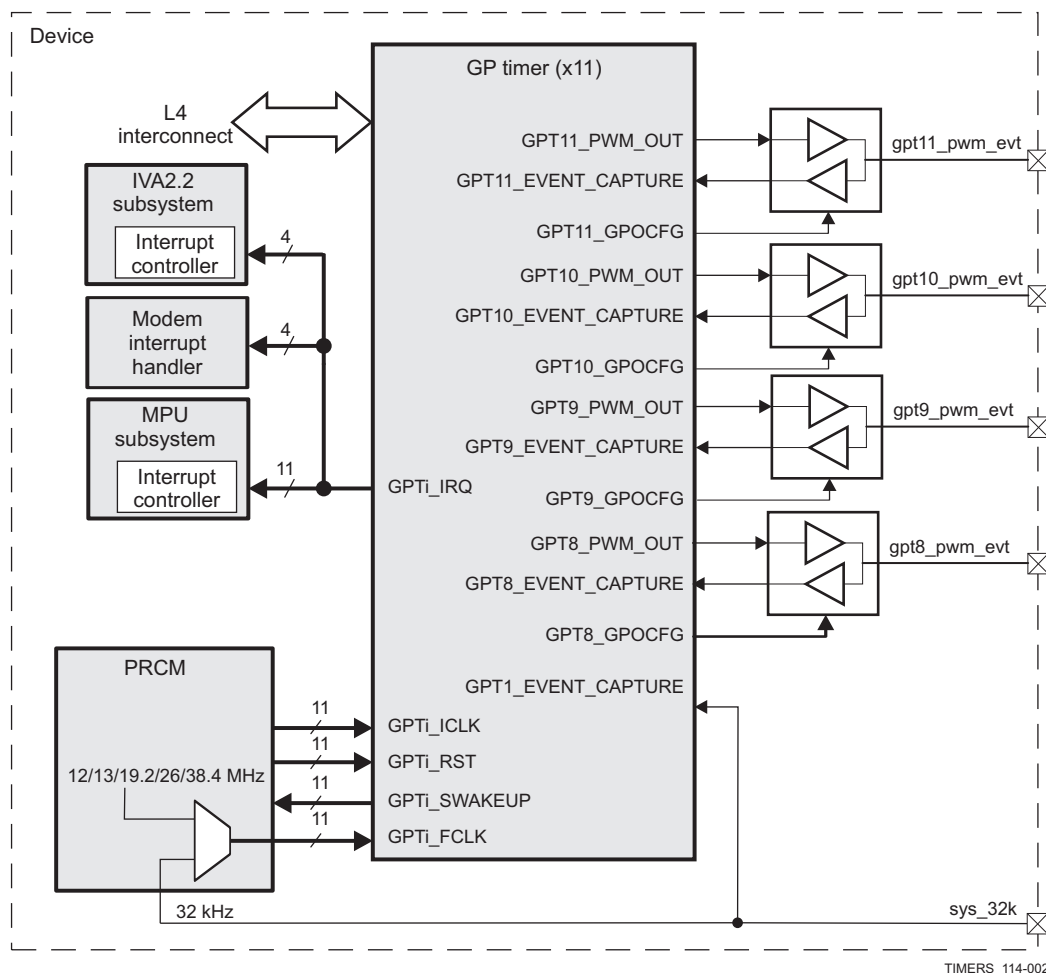

Each timer can be clocked from either the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of the clock source is made at the power, reset, clock management (PRCM) module level. For more information, see [Section 16.2.3.1, Clocking, Reset, and Power-Management Scheme](#).

GPTIMER1 has its GPT1\_EVENT\_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA2.2 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 16-2](#) shows an overview of the GP timers.

Figure 16-2. GP Timers Overview

#### 16.2.1.1 GP Timers Features

The following are the main features of the GP timers controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$  with  $n = [0:8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general-purpose using GPTi\_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768 Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

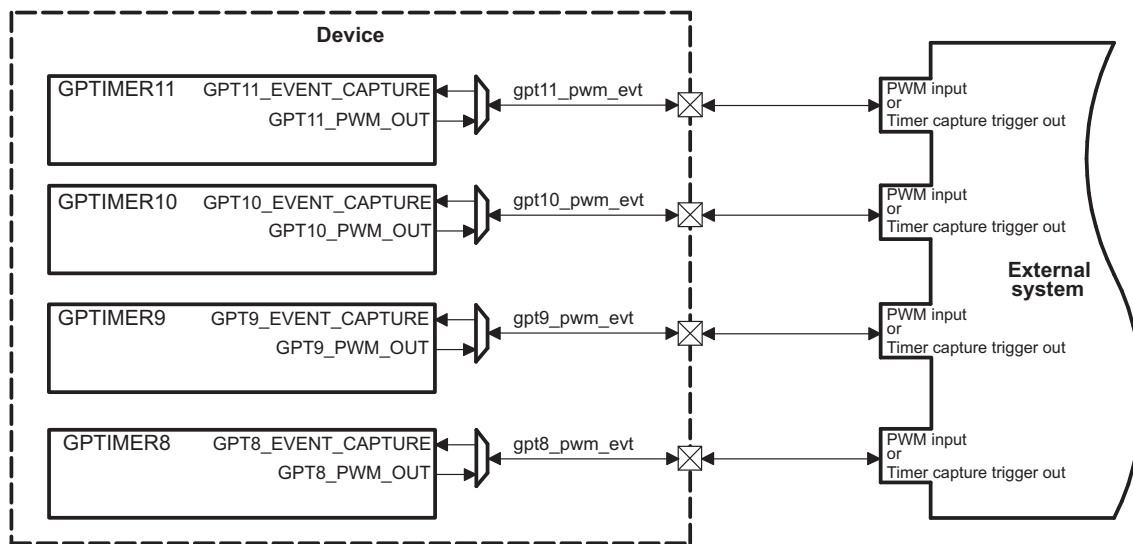

## 16.2.2 GP Timers Environment

### 16.2.2.1 GP Timers External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only GPTIMER8 through GPTIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1\_EVENT\_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Figure 16-3 shows the external system interface for the GP timers, and Table 16-1 describes the GP timer inputs and outputs.

**Figure 16-3. GP Timers External System Interface**

PU108-003

**Table 16-1. Input/Output Description**

Pin Name	Type <sup>(1)</sup>	Reset Value	Signal Name	Description
gpt8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
gpt9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
gpt10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
gpt11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

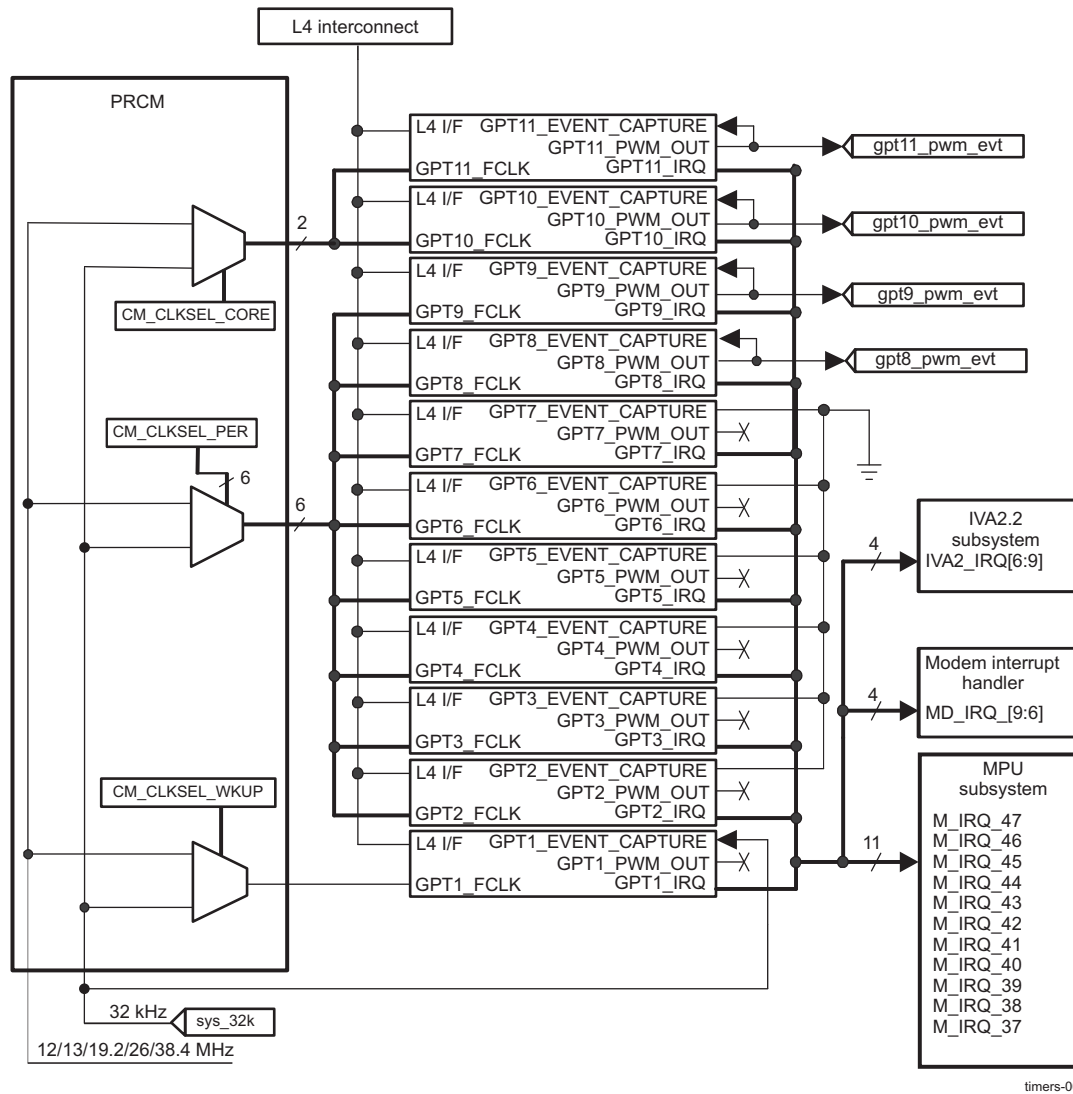

<sup>(1)</sup> When configured for that function; I = input, O = output

**Note:** The event trigger input (GPTi\_EVENT\_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi\_PWM\_OUT) is not connected.

### 16.2.3 GP Timers Integration

Figure 16-4 shows the GP timer integration in the device.

**Figure 16-4. GP Timer Integration**

#### 16.2.3.1 Clocking, Reset, and Power-Management Scheme

##### 16.2.3.1.1 Clock Management

There are two clock domains in the GP timers:

- Functional clock domain: GPTi\_FCLK is the GP timer functional clock. It is used to clock the GP timer internal logic.
- Interface clock domain: GPTi\_ICLK is the GP timer interface clock. It is used to synchronize the GP timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to GPTi\_ICLK.

Table 16-2 lists the source clocks for each GP timer in the device. For more information on clock control and domains, see [Chapter 4, Power, Reset, and Clock Management](#).

**Table 16-2. Clock, Power, and Reset Domains for GP Timers**

Timer	Interface Clock	Functional Clock	Power Domain
GPTIMER1	WKUP_L4_ICLK	GPT1_FCLK	WKUP
GPTIMER2 through GPTIMER9	PER_L4_ICLK	GPTx_ALWON_FCLK (x = 2 through 9)	PER
GPTIMER10 and 11	CORE_L4_ICLK	GPTx_FCLK (x = 10 or 11)	CORE

GP timers can be selected as the source of GPTi\_FCLK (32-kHz clock or 12, 13, 16.8, 19.2, 26, or 38.4 MHz) at the PRCM level in the corresponding registers. For more information, see [Chapter 4, Power, Reset, and Clock Management](#). [Table 16-3](#) lists the GP timer PRCM clock selection bits.

**Table 16-3. GP Timer PRCM Clock Selection Bits**

Name	Associated PRCM Clock Output	Selection Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_CLKSEL_WKUP[0] CLKSEL_GPT1
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_CLKSEL_PER [0:7] CLKSEL_GPT[2:9]
GPT10_FCLK	GPT10_FCLK	PRCM.CM_CLKSEL_CORE [6] CLKSEL_GPT10
GPT11_FCLK	GPT11_FCLK	PRCM.CM_CLKSEL_CORE [7] CLKSEL_GPT11

From a global system power-management perspective, when one or both of the GP timer clocks is no longer required, the GP timers can be deactivated at the PRCM level in the corresponding registers. [Table 16-4](#) lists the GP timer PRCM clock control bits.

**Table 16-4. GP Timer PRCM Clock Control Bits**

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1 bit	N/A
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_FCLKEN_PER [3:10] EN_GPT[2:9] bit	N/A
GPT10_FCLK	GPT10_FCLK	PRCM.CM_FCLKEN1_CORE [11] EN_GPT10 bit	N/A
GPT11_FCLK	GPT11_FCLK	PRCM.CM_FCLKEN1_CORE [12] EN_GPT11 bit	N/A
GPT1_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[0] EN_GPT1 bit	PRCM.CM_AUTOIDLE_WKUP[0] AUTO_GPT1 bit
GPT[2:9]_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[3:10] EN_GPT[2:9] bit	PRCM.CM_AUTOIDLE_PER[3:10] AUTO_GPT[2:9] bit
GPT10_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE[11] EN_GPT10 bit	PRCM.CM_AUTOIDLE1_CORE[11] AUTO_GPT10 bit
GPT11_ICLK		PRCM.CM_ICLKEN1_CORE[12] EN_GPT11 bit	PRCM.CM_AUTOIDLE1_CORE[12] AUTO_GPT11 bit

**Notes:**

- The PRCM function clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 4, Power, Reset, and Clock Management](#).
- The PRCM interface clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 4, Power, Reset, and Clock Management](#).
- The PRCM AUTOIDLE bits are used to link/unlink the GP timers from the clock domain transitions related to the GPTi\_ICLK clocks.
- For further details about source clock gating and domain transitions, see [Chapter 4, Power, Reset, and Clock Management](#).

GP timer modules also have an internal bit, GPTi.TIOCP\_CFG[0] AUTOIDLE. The GP timer AUTOIDLE bit is used to apply an internal interface clock gating strategy.

At the PRCM level, when all conditions to shut off the PRCM functional or interface output clocks are met (see [Chapter 4, Power, Reset, and Clock Management](#), for details), the PRCM automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPTi.TIOCP\_CFG[4:3] IDLEMODE bit. [Table 16-5](#) lists the IDLEMODE settings and the related acknowledgement modes.

**Table 16-5. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi\_FCLK and GPTi\_ICLK gating. The GPTi.TIOCP\_CFG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (GPTi\_FCLK, GPTi\_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if GPTi\_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi\_ICLK and the associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi\_ICLK and others are associated with GPTi\_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 16-6 lists the CLOCKACTIVITY settings and the associated features.

**Table 16-6. CLOCKACTIVITY Settings**

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	Both GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means both GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is finished during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

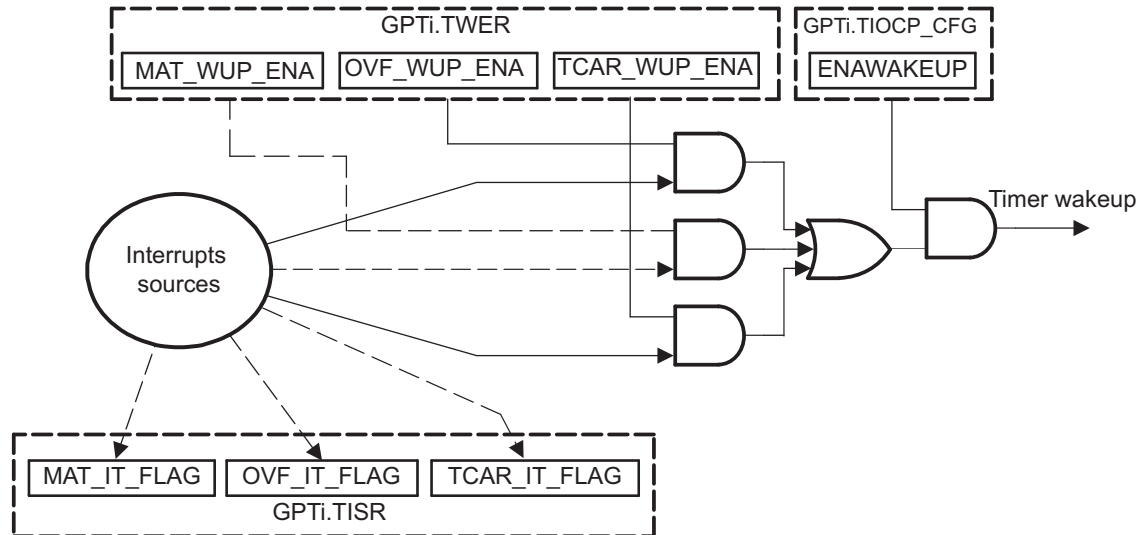

**CAUTION**

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the GP timer is disabled in both CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

**16.2.3.1.2 Wake-Up Capability**

If the GPTi.TIOCP\_CFG[4:3] IDLEMODE bit field sets the smart-idle mode, the timer module evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPTi.TIOCP\_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 16-5 shows the wake-up request generation. For more information on the GP timer clock control, see Section 16.2.3.1.1, *Clock Management*.

**Figure 16-5. Wake-Up Request Generation**

PU108-005

The timer wake-up enable register (GPTi.TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPTi.TWER register is programmed synchronously with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPTi.TCRR), a timer match (the compare result of GPTi.TCRR and GPTi.TMAR matches the counter value), and a timer capture (an external pulse transition of the correct polarity is detected on the GPTi\_EVENT\_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending wake-up event is reset when the set status bit is overwritten by 1.

---

**Note:** The status bit must be reset to re-enter idle mode.

---

### 16.2.3.1.3 Reset and Power Management

GPTIMER1 belongs to the WKUP power domain. As part of that domain, this GP timer is sensitive to a WKUP\_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and the WKUP\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

GPTIMER2 through GPTIMER9 belong to the PER power domain. As part of that domain, these GP timers are sensitive to a PER\_RST signal issued by the PRCM module. For further details about the PER power domain implementation and the PER\_RST signal, see [Chapter 4, Power, Reset, Clock Management](#).

GPTIMER10 and GPTIMER11 belong to the CORE power domain. As part of that domain, these GP timers are sensitive to a CORE\_RST signal issued by the PRCM module. For further details about the CORE power domain implementation and the CORE\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

### 16.2.3.2 Software Reset

Two bit fields (GPTi.TIOCP\_CFG[1] SOFTRESET and GPTi.TSICR[1] SFT) can generate a software reset of the GP timer. For both of these bits, all read accesses return 0.

The GPTi.TIOCP\_CFG[1] SOFTRESET bit allows resetting the functional and interface domains. The GPTi.TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPTi.TISTAT[0] RESETDONE bit. This bit field monitors the internal reset status.

### 16.2.3.3 GP Timer Interrupts

Table 16-7 lists the interrupt mapping from the 12 GP timers to the three internal processors.

**Table 16-7. Timer Interrupt Names and Processor IRQ Mapping**

Timer	Interrupt Name	Mapping	Comments
GPTIMER 1	GPT1_IRQ	M_IRQ_37	GPTIMER1 interrupt to MPU
GPTIMER2	GPT2_IRQ	M_IRQ_38	GPTIMER2 interrupt to MPU
GPTIMER3	GPT3_IRQ	M_IRQ_39	GPTIMER3 interrupt to MPU
GPTIMER4	GPT4_IRQ	M_IRQ_40	GPTIMER4 interrupt to MPU
GPTIMER5	GPT5_IRQ	M_IRQ_41	GPTIMER5 interrupt to MPU
		IVA2_IRQ[6]	GPTIMER5 interrupt to IVA2.2
GPTIMER6	GPT6_IRQ	M_IRQ_42	GPTIMER6 interrupt to MPU
		IVA2_IRQ[7]	GPTIMER6 interrupt to IVA2.2
		MD_IRQ_6	GPTIMER6 interrupt to modem subsystem (D2D)
GPTIMER7	GPT7_IRQ	M_IRQ_43	GPTIMER7 interrupt to MPU
		IVA2_IRQ[8]	GPTIMER7 interrupt to IVA2.2
		MD_IRQ_7	GPTIMER7 interrupt to modem subsystem (D2D)
GPTIMER8	GPT8_IRQ	M_IRQ_44	GPTIMER8 interrupt to MPU
		IVA2_IRQ[9]	GPTIMER8 interrupt to IVA2.2
		MD_IRQ_8	GPTIMER8 interrupt to modem subsystem (D2D)
GPTIMER9	GPT9_IRQ	M_IRQ_45	GPTIMER9 interrupt to MPU
		MD_IRQ_9	GPTIMER9 interrupt to modem subsystem (D2D)
GPTIMER10	GPT10_IRQ	M_IRQ_46	GPTIMER10 interrupt to MPU
GPTIMER11	GPT11_IRQ	M_IRQ_47	GPTIMER11 interrupt to MPU

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt enable register (GPTi.TIER). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending interrupt event is reset when the set status bit is overwritten by a1.

### 16.2.4 GP Timers Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPTi.TIER register for the interrupt features and a dedicated bit of the GPTi.TWER register for the wakeup. In addition, GPTIMER1, GPTIMER2, and GPTIMER10 have implemented a mechanism to generate an accurate tick interrupt.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 16.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

16.2.4.1 GP Timers Block Diagram

Figure 16-6 shows the block diagram of common GP timers, and Figure 16-7 shows the block diagram of GP timers with 1-ms tick generation module.

Figure 16-6. Block Diagram of GPTIMER3 through GPTIMER9 and GPTIMER11

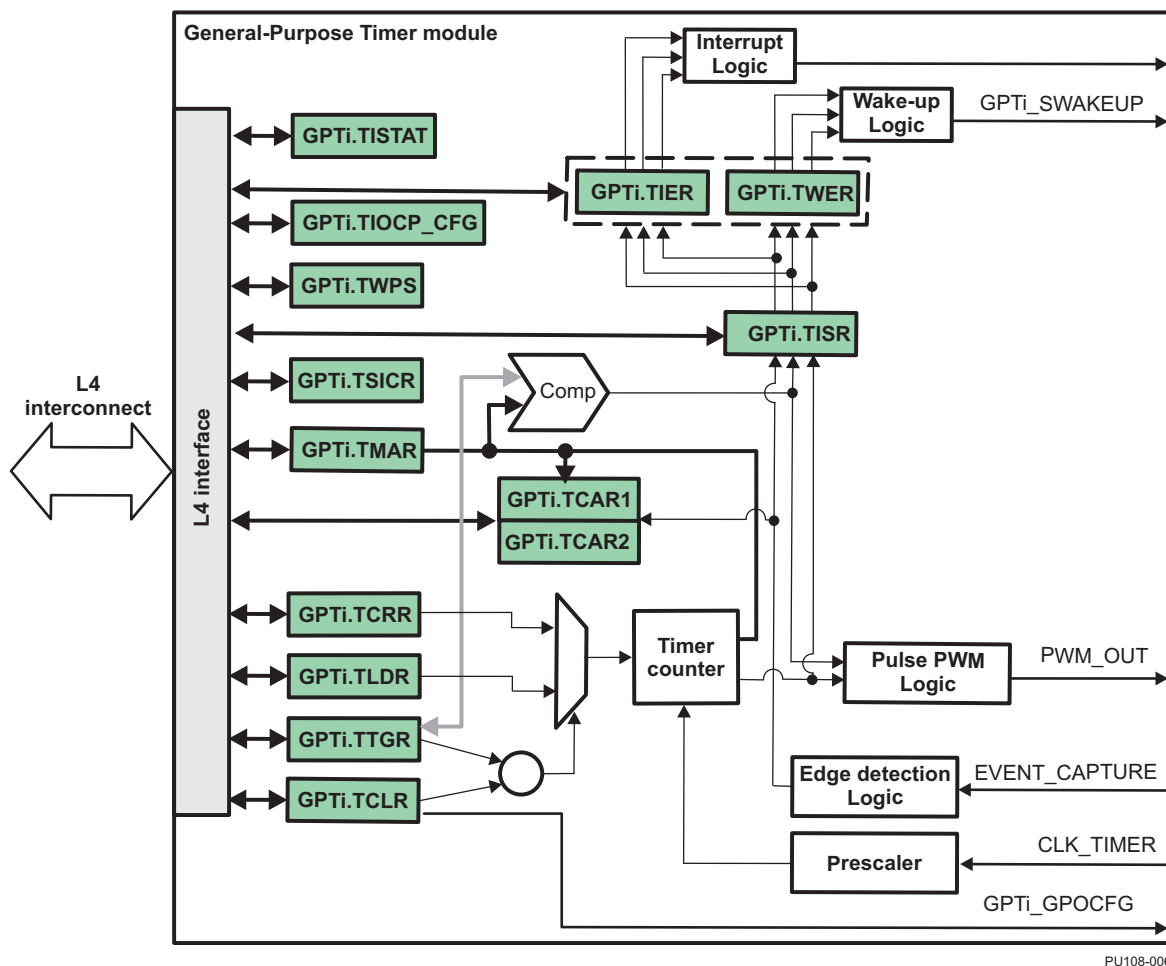

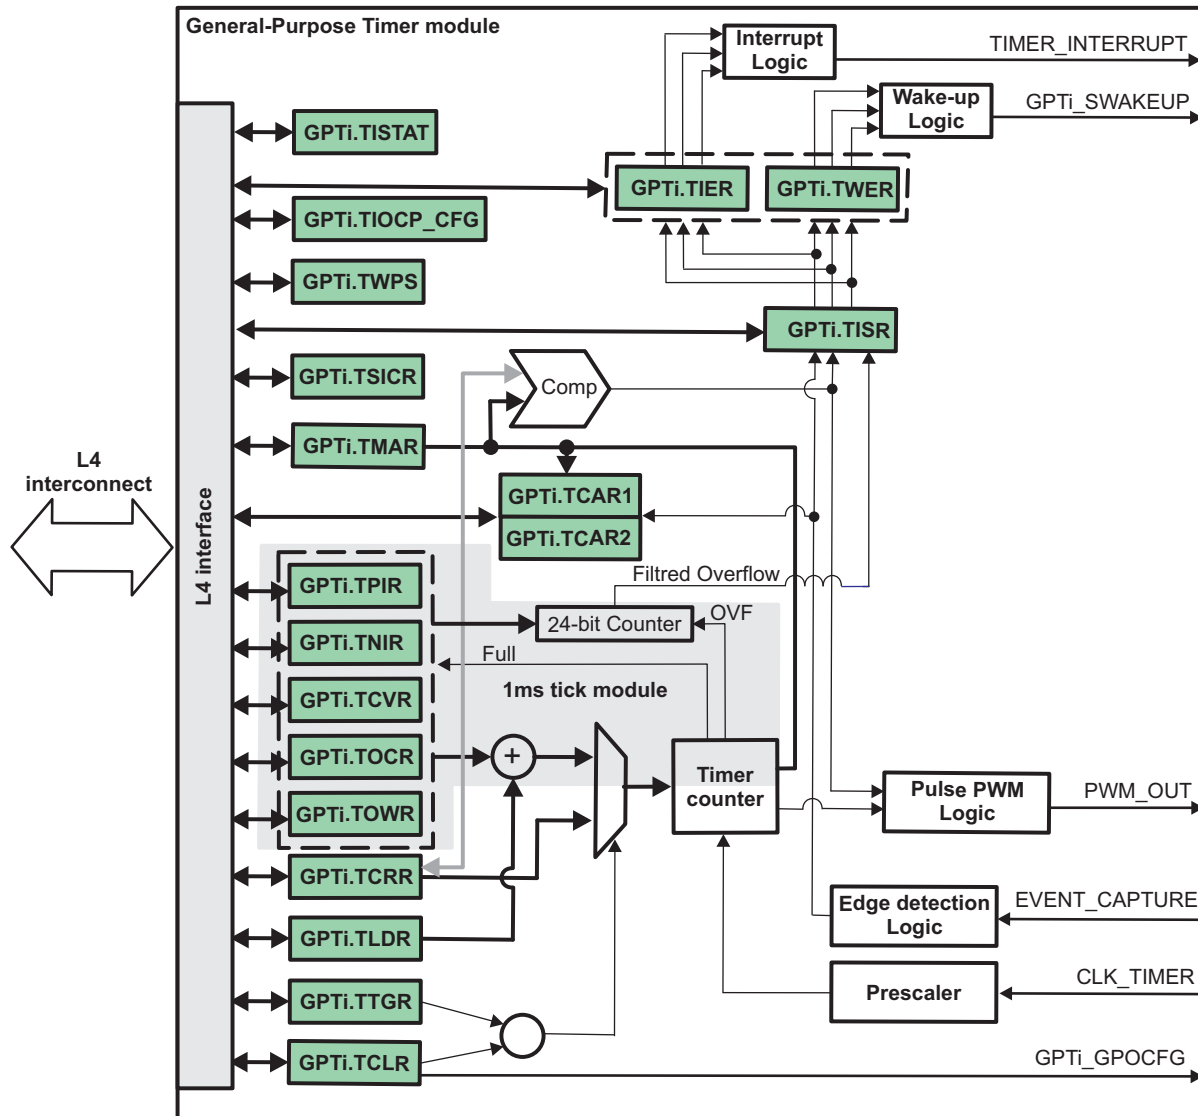

Figure 16-7. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

PU108-007

### 16.2.4.2 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPTi.TCLR[0] ST bit). The timer counter register (GPTi.TCRR) can be loaded when stopped or on-the-fly (while counting). GPTi.TCRR can be loaded directly by a GPTi.TCRR write access with a new timer value. The GPTi.TCRR register can also be loaded with the value held in the timer load register GPTi.TLDR by a trigger register (GPTi.TTGR) write access. The GPTi.TCRR loading is done regardless of the GPTi.TTGR written value. The timer counter register GPTi.TCRR value can be read when stopped or captured on-the-fly by a GPTi.TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPTi.TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPTi.TCLR[1] AR bit set to 1), the GPTi.TCRR register is reloaded with the timer load register (GPTi.TLDR) value after a counting overflow occurs.

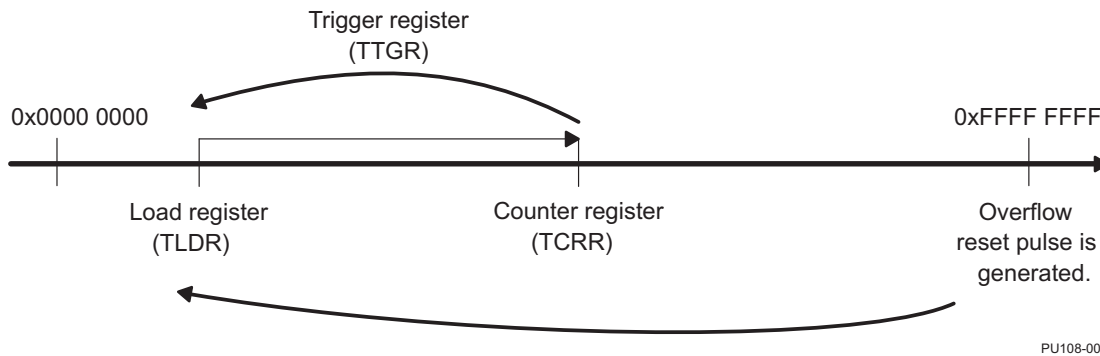

**CAUTION**

Do not put the overflow value (0xFFFFFFFF) in the GPTi.TLDR register because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer interrupt enable register (GPTi.TIER[1] OVF\_IT\_ENA bit set to 1), the interrupt is enabled after 10 \* GPTi.ICLK clock cycles. A dedicated output pin (timer PWM) can be programmed in GPTi.TCLR[12] through GPTi.TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPTi.TCLR[12] PT bit selects pulse/toggle modulation (GPTi.TCLR[11:10] TRG bit field select trigger mode).

Figure 16-8 shows the GPTi.TCRR timing value.

**Figure 16-8. GPTi.TCRR Timing Value**

PU108-008

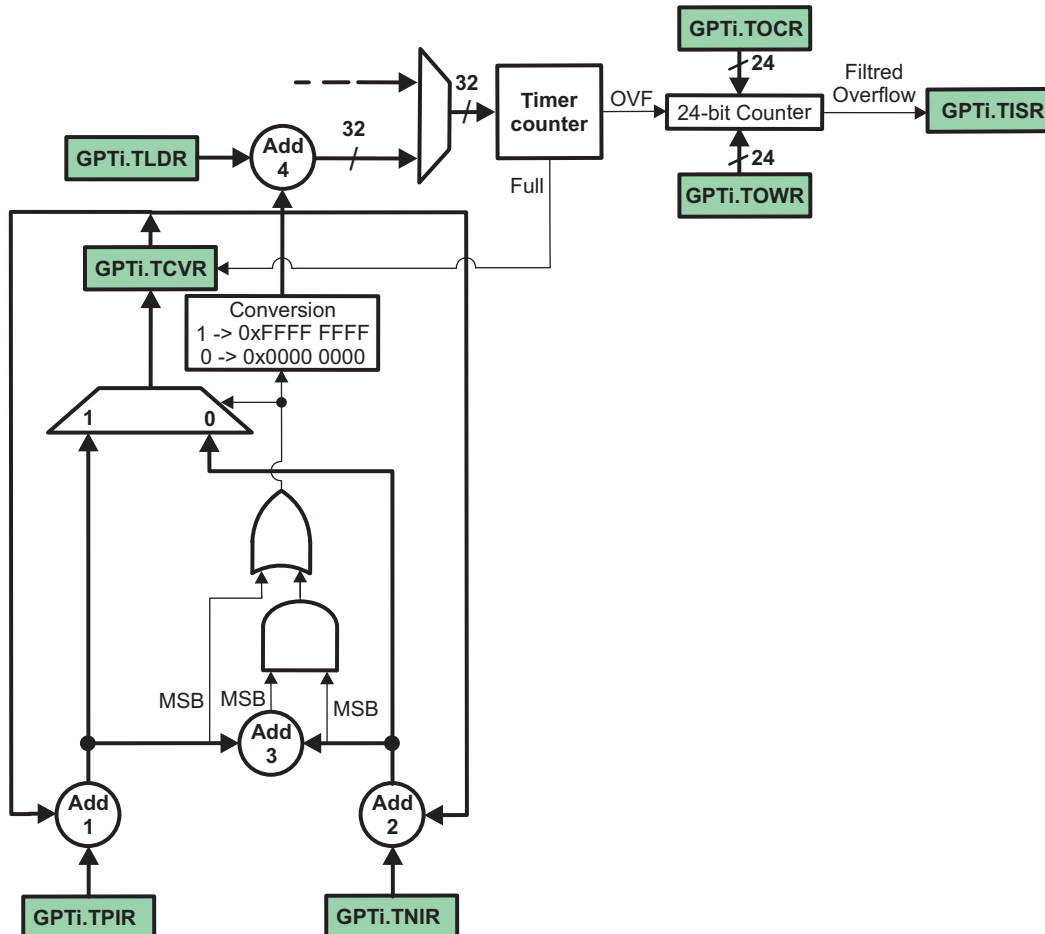

**16.2.4.2.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)**

Because the timer input clock is 32,768 Hz, the interrupt period is not exactly 1 ms. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations to the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. Refer to Figure 16-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPTi.TPIR[31:0] POSITIVE\_INC\_VALUE bit field) and the timer negative increment register (GPTi.TNIR[31:0] NEGATIVE\_INC\_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 16-9. Block Diagram of the 1-ms Tick Module

PU108-009

The GPTi.TPIR, GPTi.TNIR, and GPTi.TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPTi.TCRR[31:0] TIMER\_COUNTER bit field) is the value of the GPTi.TLDR[31:0] LOAD\_VALUE bit field (period less than 1 ms) or the value of GPTi.TLDR[31:0] LOAD\_VALUE - 1 (period greater than 1 ms).

Table 16-8 lists the value loaded in the GPTi.TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 16-8. Value Loaded in GPTi.TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of GPTi.TCRR Register
0	0	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	0	1	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1

The values of the GPTi.TPIR and GPTi.TNIR registers are calculated using the following formula:

- Positive increment value =  $(\text{INTEGER}[\text{Fclk} * \text{Ttick}] + 1) * 1\text{e}6 - (\text{Fclk} * \text{Ttick} * 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[\text{Fclk} * \text{Ttick}] * 1\text{e}6) - (\text{Fclk} * \text{Ttick} * 1\text{e}6)$

---

**Note:** Fclk clock frequency (kHz)

Ttick tick period (ms)

---

The timer overflow counter register (GPTi.TOCR) and the timer overflow wrapping register (GPTi.TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR register. When the 24-bit TOCR register values match the value in the 24-bit TOWR register and the timer overflow is asserted, the TOCR register is reset and an interrupt is generated to the TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPTi.TPIR[31:0] POSITIVE\_INC\_VALUE = 232000
- GPTi.TNIR[31:0] NEGATIVE\_INC\_VALUE = -768000
- GPTi.TLDR[31:0] LOAD\_VALUE = 0xFFFFFEE0

---

**Note:** Any value of the tick period can be generated with the appropriate value of the GPTi.TPIR, GPTi.TNIR, and GPTi.TLDR registers.

By default, the GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

---

### 16.2.4.3 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT\_CAPTURE), the timer value in the GPTi.TCRR register can be captured and saved in the GPTi.TCAR1 or GPTi.TCAR2 register function of the mode selected in the GPTi.TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT\_CAPTURE).

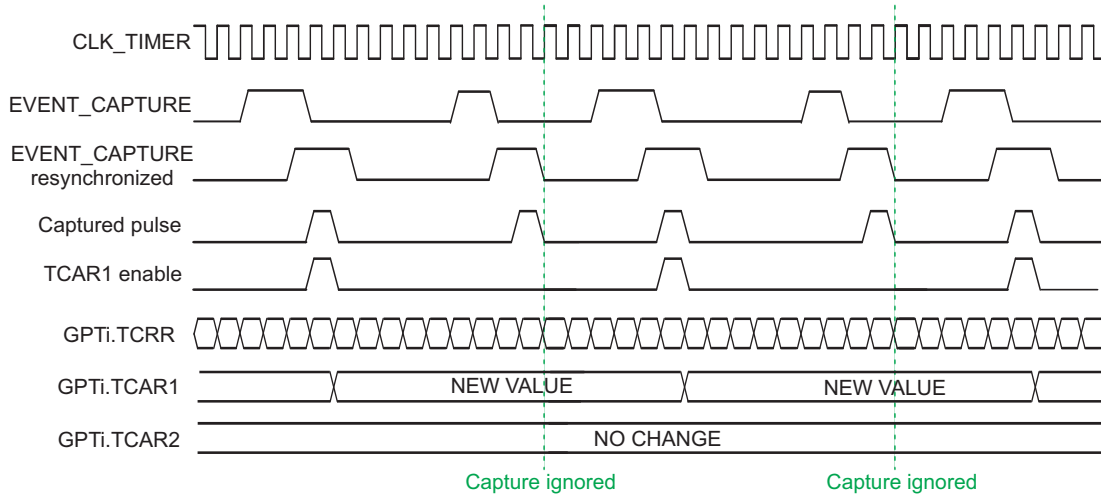

The rising edge, falling edge, or both, can be selected in the GPTi.TCLR[9:8] TCM field to trigger the timer counter capture. The module sets the GPTi.TISR[2] TCAR\_IT\_FLAG bit when an active edge is detected, and at the same time, the counter value GPTi.TCRR is stored in timer capture register GPTi.TCAR1 or GPTi.TCAR2, as follows:

- If the GPTi.TCLR[13] CAPT\_MODE bit is 0, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and all the next events are ignored (no update on the GPTi.TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPTi.TISR[2] TCAR\_IT\_FLAG bit is cleared by writing 1 in it.
- If the GPTi.TCLR[13] CAPT\_MODE bit is 1, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPTi.TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPTi.TCAR1/GPTi.TCAR2 and no interrupt triggering) until the detection logic is reset or GPTi.TISR[2] TCAR\_IT\_FLAG bit is cleared by writing 1 in it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT\_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served the GPTi.TISR[2] TCAR\_IT\_FLAG bit (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPTi.TCLR[9:8] TCM field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT\_CAPTURE). An input negative or positive pulse can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt enable bit is set in the GPTi.TIER[2] TCAR\_IT\_ENA bit. See the examples in [Figure 16-10](#) and [Figure 16-11](#).

In Figure 16-10, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT\_MODE is 0. Only the rising edge of EVENT\_CAPTURE triggers a capture in the GPTi.TCAR1 and GPTi.TCAR2 registers, and only the GPTi.TCAR1 register updates.

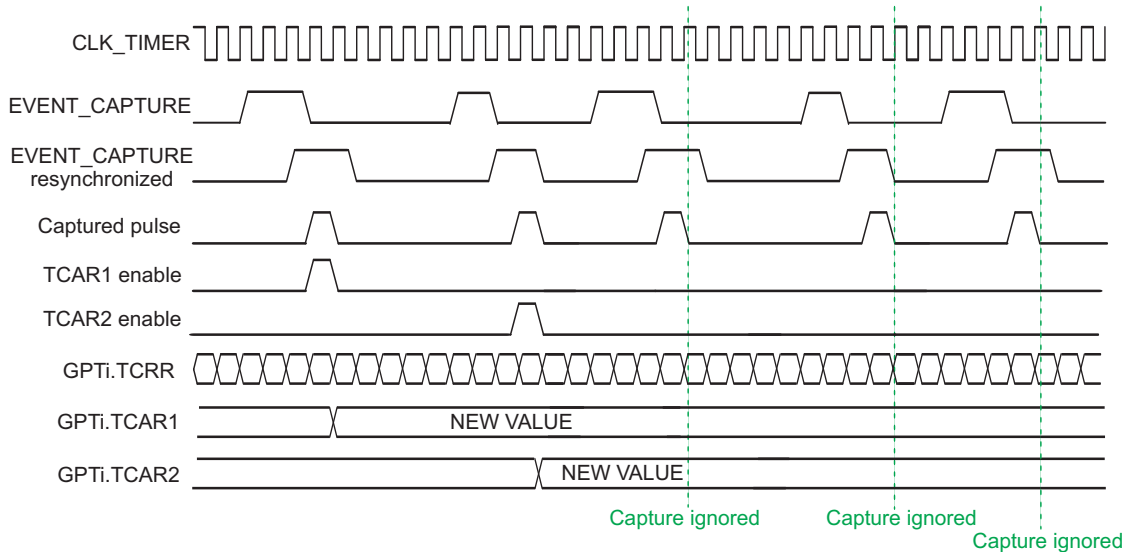

**Figure 16-10. Capture Wave Example for GPTi.TCLR[13] CAPT\_MODE = 0**

PU108-010

In Figure 16-11, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT\_MODE is 1. Only the rising edge of EVENT\_CAPTURE triggers a capture in the GPTi.TCAR1 register on the first enabled event, and the GPTi.TCAR2 register updates on the second enabled event.

**Figure 16-11. Capture Wave Example for GPTi.TCLR[13] CAPT\_MODE = 1**

PU108-011

#### 16.2.4.4 Compare Mode Functionality

When the compare enable register GPTi.TCLR[6] CE bit is set to 1, the timer value (GPTi.TCRR[31:0] TIMER\_COUNTER field) is continuously compared to the value held in the timer match register (GPTi.TMAR). The GPTi.TMAR[31:0] COMPARE\_VALUE value can be loaded at any time (timer counting or stopped). When the GPTi.TCRR and the GPTi.TMAR values match, an interrupt is issued, if the GPTi.TIER[0] MAT\_IT\_ENA bit is set.

The dedicated output pin (timer PWM) can be programmed in the GPTi.TCLR[12] PT bit through the GPTi.TCLR[11:10] TRG field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 16.2.4.5 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPTi.TCLR[5] PRE bit is set. The GPTi.TCLR[4:2] PTV field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 16-9 lists the prescaler/timer reload values versus contexts.

**Table 16-9. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPTi.TLDR[31:0]
TCCR write	Reset	GPTi.TCRR[31:0]
TTGR write	Reset	GPTi.TLDR[31:0]
Stop	Reset	Frozen

#### 16.2.4.6 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPTi.TCLR[11:10] TRG field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

#### CAUTION

In toggle mode when GPTi.TCLR[11:10] TRG = 0x2 (overflow and match), the first event that will toggle the PWM line is an overflow event. If a match event occurs first, it will not toggle the PWM line. Figure 16-13 illustrates those.

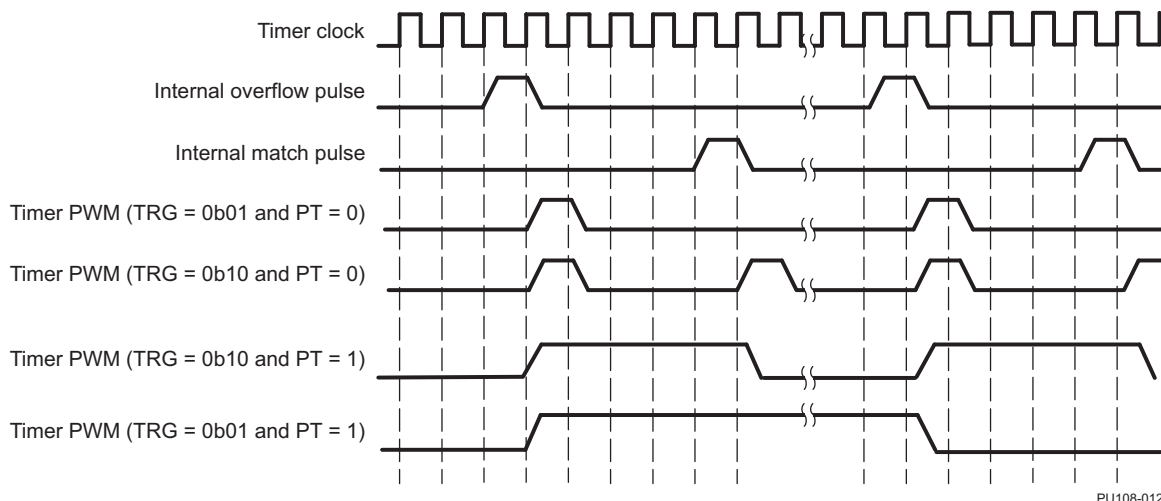

The GPTi.TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPTi.TCLR[11:10] TRG field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 16-12, the internal overflow pulse is set each time (0xFFFF FFFF - GPTi.TLDR[31:0] LOAD\_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPTi.TMAR register value. According to the value of the GPTi.TCLR[12] PT and GPTi.TCLR[11:10] TRG bits, the timer provides pulse or PWM event on the output pin (timer PWM).

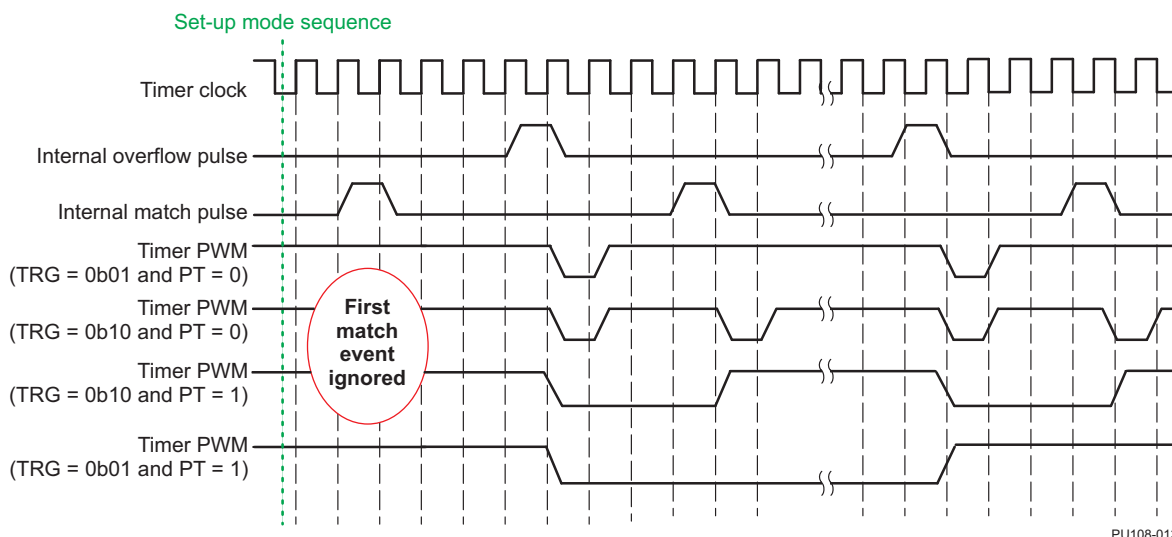

The GPTi.TLDR and GPTi.TMAR registers must keep values smaller than the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPTi.TMAR register and the value in the GPTi.TLDR register must be at least two units. When match event is used, the compare mode GPTi.TCLR[6] CE bit must be set.

In Figure 16-12, the GPTi.TCLR[7] SCPWM bit is set to 0. In Figure 16-13, the GPTi.TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPTi.TCLR[7] SCPWM bit).

**Figure 16-12. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 0**

**Figure 16-13. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 1**

**16.2.4.7 Timer Counting Rate**

The timer rate is defined by the following values:

- Value of the prescaler fields (GPTi.TCLR[5] PRE bit and GPTi.TCLR[4:2] PTV field)
- Value loaded into the timer load register (GPTi.TLDR)

Table 16-10 lists prescaler clock ratio values.

**Table 16-10. Prescaler Clock Ratio Values**

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

**Table 16-10. Prescaler Clock Ratio Values (continued)**

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow-rate is expressed as:

$$\text{OVF\_Rate} = (\text{0xFFFF FFFF} - \text{GPTn.TLDR} + 1) * (\text{timer-functional clock period}) * \text{PS}$$

With (timer-functional clock period) =  $1 / (\text{timer-functional clock frequency})$  and  $\text{PS} = 2^{(\text{PTV} + 1)}$  if prescaler is enabled, or  $\text{PS} = 1$  if prescaler is disabled.

#### CAUTION

Internal resynchronization causes any write to the GPTn.TCLR[1] ST bit to have some latency before the register is updated:

2.5 \* functional clock cycles write\_GPTn.TCLR\_latency 3.5 \* functional clock cycles

Remember to take this latency into account whenever the timer must be started or stopped by a software change to the GPTn.TCLR[1] ST bit.

#### CAUTION

- In the non-PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and a GPTn.TCLR[5] PRE field equal to 0, the timer output period is as listed in [Table 16-11](#).

**Table 16-11. Value and Corresponding Interrupt Period**

GPTi.TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 $\mu\text{s}$
0xFFFF FFFE	65.5 $\mu\text{s}$

### 16.2.5 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPTi.TIOCP\_CFG[5] EMUFREE bit.

If the GPTi.TIOCP\_CFG[5] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPTi.TIOCP\_CFG[5] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (gpti\_pwm\_evt, with i=[9:12]) is internally synchronized on two timer-clock rising edges.

## 16.2.6 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration.

All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB). Write operations to the GP timer registers (GPTi.TIDR, GPTi.TIOCP\_CFG, GPTi.TISR, GPTi.TIER, GPTi.TWER, and GPTi.TSICR) can skip the MSB access if it is not necessary to update the 16 MSBs of the register.

Write operations to any functional register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, and GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10) must be complete (the MSB must be written even if the MSB data is not used).

### 16.2.6.1 Writing to Timer Registers

The host uses the L4 interface to write the following registers synchronously with the timer interface clock:

- GPTi.TLDR
- GPTi.TCRR
- GPTi.TIER
- GPTi.TISR
- GPTi.TCLR
- GPTi.TIOCP\_CFG
- GPTi.TWER
- GPTi.TTGR
- GPTi.TSICR
- GPTi.TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPTi.TPIR
- GPTi.TNIR
- GPTi.TCVR
- GPTi.TOCR
- GPTi.TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

#### 16.2.6.1.1 Write Posting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later, because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status register GPTi.TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPTi.TCRR does not add any resynchronization latency; the current value is always available.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{L4 interface clock})/4$

#### 16.2.6.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 0.

This mode uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

#### 16.2.6.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPTi.TCRR, GPTi.TCAR1, and GPTi.TCAR2) captures the current timer counter value. This must be followed by reading the 16MSBs.

IVA2.2 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

---

**Note:** LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

---

## 16.3 General-Purpose Timers Register Manual

### 16.3.1 GP Timer Register Map

#### 16.3.1.1 Instance Summary

Table 16-12 lists the base address and block size for the GP timer module instances. All timers are memory mapped to the L4 peripheral bus memory space.

**Table 16-12. GP Timer Instance Summary**

Module Name	Base Address	Size
GPTIMER1	0x4831 8000	4K bytes
GPTIMER2	0x4903 2000	4K bytes
GPTIMER3	0x4903 4000	4K bytes
GPTIMER4	0x4903 6000	4K bytes
GPTIMER5	0x4903 8000	4K bytes
GPTIMER6	0x4903 A000	4K bytes
GPTIMER7	0x4903 C000	4K bytes
GPTIMER8	0x4903 E000	4K bytes
GPTIMER9	0x4904 0000	4K bytes
GPTIMER10	0x4808 6000	4K bytes
GPTIMER11	0x4808 8000	4K bytes

### 16.3.2 GP Timer Register Mapping Summary

#### CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 16-13 through Table 16-15 provide the register summary and associated offset addresses for the 11 GP timer internal registers. (Example: The physical address for the **TCLR** register of GPTIMER8 is 0x4903 E024.)

**Table 16-13. GPTIMER1 to GPTIMER4 Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address (GPTIMER1)	Physical Address (GPTIMER2)	Physical Address (GPTIMER3)	Physical Address (GPTIMER4)

	0x4904 0010		GPT10
	0x4808 6010		GPT11
	0x4808 8010		GPT11
<b>Description</b>	This register controls the various parameters of the GP timer L4 interface.		
<b>Type</b>	RW		

Bits	Field Name	DESCRIPTION	Type	Reset
31:10	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x00000000
9:8	CLOCKACTIVITY	Clock activity during wakeup mode period: 0x0: L4 interface and Functional clocks can be switched off. 0x1: L4 interface clock is maintained during wake-up period; Functional clock can be switched off. 0x2: L4 interface clock can be switched off; Functional clock is maintained during wake-up period. 0x3: L4 interface and Functional clocks are maintained during wake-up period.	RW	0x0
7:6	Reserved	Write 0s for future compatibility. Reads return 0.	R	0x0

Bits	Field Name	DESCRIPTION	Type	Reset
5	EMUFREE	Emulation mode 0x0: Timer counter frozen in emulation 0x1: Timer counter free-running in emulation	RW	0
4:3	IDLEMODE	Power management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved. Do not use.	RW	0x0
2	ENAWAKEUP	Wake-up feature global control 0x0: No wake-up line assertion in idle mode 0x1: Wake-up line assertion enabled in smart-idle mode	RW	0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal L4 interface clock gating strategy 0x0: L4 interface clock is free-running. 0x1: Automatic L4 interface clock gating strategy is applied, based on the L4 interface activity.		0

## 16.4 Watchdog Timers

### 16.4.1 WDTs Overview

The device includes two instances of the 32-bit WDT: WDT2 and WDT3. Figure 16-14 shows how each timer is connected in the device.

**Note:** WDT<sub>i</sub> (where *i* is the watchdog timer instance: *i* = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA2 watchdog timer

Each WDT is an upward counter capable of generating both a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU WDT serves resets to the PRCM module (its interrupt outputs are unused), and the IVA2 WDT serves watchdog interrupts to the MPU (its reset outputs are unused).

The WDTs can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA2 WDTs have the 32-kHz clock for their timer clock input.

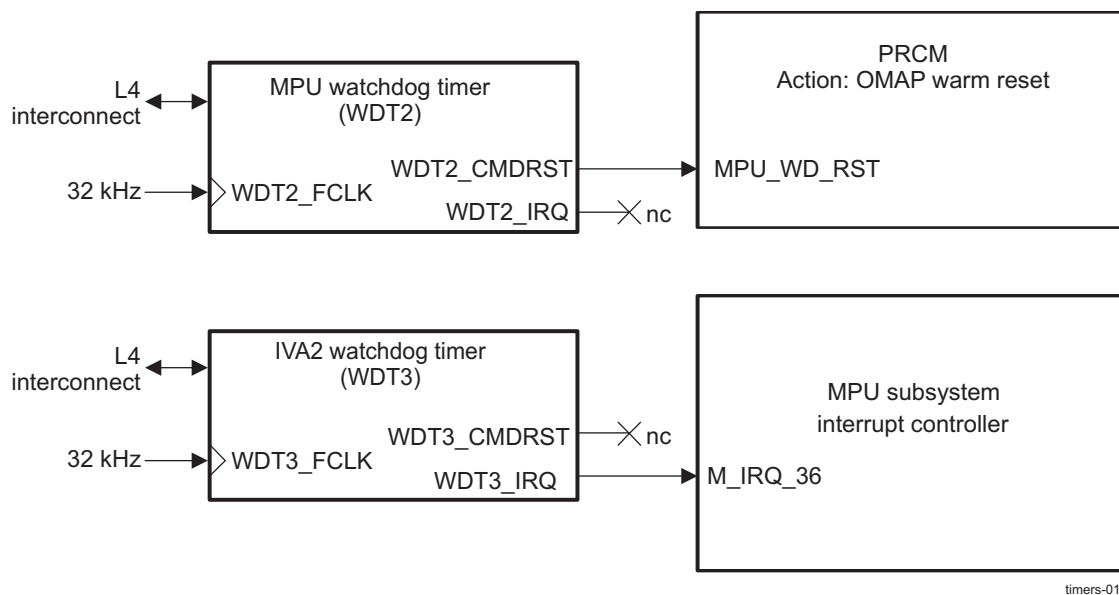

The MPU WDT directly generates a warm reset condition on overflow. The IVA2 WDT generates an MPU interrupt condition on overflow, which can be used by the application software via the PRCM to indirectly trigger a reset condition (that is, to the IVA2 subsystem).

The MPU WDT connects to a single target agent port on the L4 interconnect.

**Table 16-56. WD Timers Default State for GP and EMU devices**

Timer	Device			
	EMU		GP	
MPU WDTIMER2	Enabled	Running	Enabled	Running
IVA2 WDTIMER3	Enabled	NOT Running	Enabled	NOT Running

**Figure 16-14. WDTs Block Diagram**

#### 16.4.1.1 WDT Features

The following are the main features of the WDT controllers:

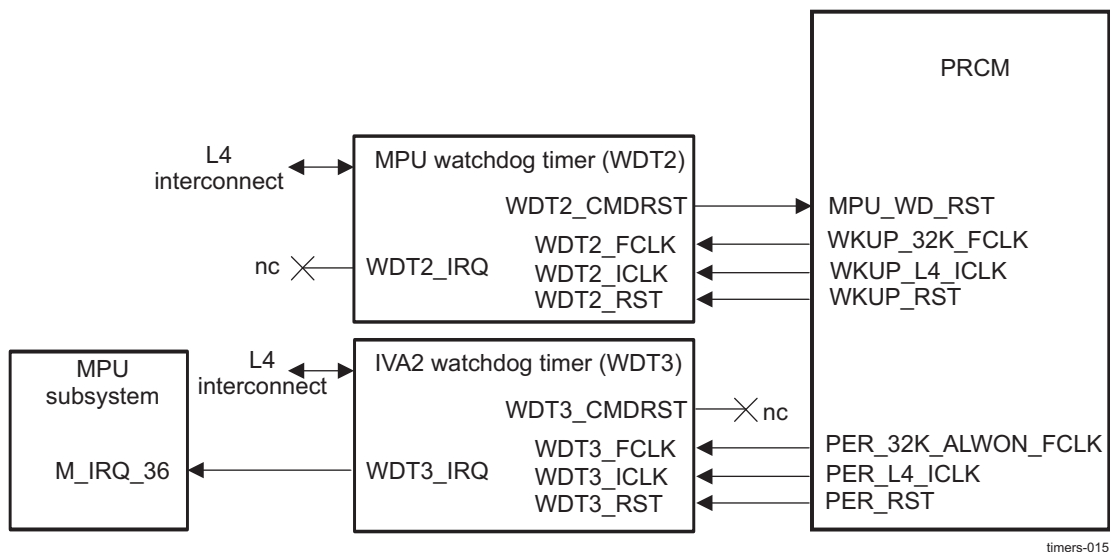

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 11-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source ( $2^n$  with  $n=[0:7]$ )
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- WDTs are reset either on power-on or after a warm reset.
- Reset or interrupt actions when a timer overflow condition occurs
- WDT generates either a reset or an interrupt in its hardware integration (WDT2, or WDT3).

### 16.4.2 WDT Integration

Figure 16-15 shows the integration of the WDT in the device.

Figure 16-15. WDT Integration

#### 16.4.2.1 Clocking, Reset, and Power-Management Scheme

##### 16.4.2.1.1 Clock Management

There are two clock domains in the WDTs:

- Functional clock domain: WDTi\_FCLK is the WDT functional clock. It is used to clock the WDT internal logic.
- Interface clock domain: WDTi\_ICLK is the WDT interface clock. It is used to synchronize the WDT L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi\_ICLK.

Table 16-57 lists the the source clocks for each WDT in the device. For more information on clock control and domains, see Chapter 4, Power, Reset, and Clock Management.

**Table 16-57. Clock, Power, and Reset Domains for WDTs**

Timer	Interface Clock	Functional Clock	Power Domain
MPU WDT	WKUP_L4_ICLK	WKUP_32K_FCLK	WKUP
IVA2 WDT	PER_L4_ICLK	PER_32K_ALWON_FCLK	PER

From a global system power-management perspective, when one or both of the WDT clocks is no longer required, the WDTs can be deactivated at the PRCM level in the corresponding registers. [Table 16-58](#) lists the WDT PRCM clock control bits.

**Table 16-58. WDT PRCM Clock Control Bits**

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
WDT2_FCLK	WKUP_32K_FCLK	PRCM.CM_FCLKEN_WKUP[5] EN_WDT2 bit	N/A
WDT3_FCLK	PER_32K_ALWON_FCLK	PRCM.CM_FCLKEN_PER[12] EN_WDT3 bit	N/A
WDT2_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[5] EN_WDT2 bit	PRCM.CM_AUTOIDLE_WKUP[5] AUTO_WDT2 bit
WDT3_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[12] EN_WDT3 bit	PRCM.CM_AUTOIDLE_PER[12] AUTO_WDT3 bit

**Notes:**

- The PRCM function clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 4, Power, Reset, and Clock Management](#).
- The PRCM interface clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient condition. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see [Chapter 4, Power, Reset, and Clock Management](#).
- The PRCM AUTOIDLE bits are used to link/unlink the WDTs from the clock domain transitions related to the GPTi\_ICLK clocks.
- For further details about source clocks gating and domain transitions, see [Chapter 4, Power, Reset, and Clock Management](#).

At the PRCM level, when the conditions to shut off the PRCM functional or interface output clocks are met (see [Chapter 4, Power, Reset, and Clock Management](#), for details), the PRCM automatically launches a hardware handshake protocol to ensure the WDT is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the WDT.

Although this handshake is a hardware function and out of software control, the way the WDT acknowledges the PRCM IDLE request is configurable through the WDTi.WD\_SYSCONFIG[4:3] IDLEMODE bit. [Table 16-59](#) lists the IDLEMODE settings and the related acknowledgement modes.

**Table 16-59. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The WDT acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The WDT never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures the clocks remain active; it is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

**Table 16-59. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The WDT acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQs requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the WDT also offers an additional granularity on WDTi\_FCLK and WDTi\_ICLK gating. The WDTi.WD\_SYSCONFIG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (WDTi\_FCLK, WDTi\_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the WDT to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if WDTi\_FCLK is not to be shut down on a PRCM IDLE request, the WDT considers only WDTi\_ICLK and the associated pending activities before acknowledging the request.

Some WDT features are associated with WDTi\_ICLK, and others are associated with WDTi\_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the WDT acknowledges an IDLE request.

Table 16-60 lists the CLOCKACTIVITY settings.

**Table 16-60. CLOCKACTIVITY Settings**

CLOCKACTIVITY Value	WDTi_ICLK Effects	WDTi_FCLK Effects	Description
00	OFF	OFF	Both WDTi_ICLK and WDTi_FCLK are considered for generating the acknowledge. This setting also means both WDTi_FCLK and WDTi_ICLK are likely to be shut down on a PRCM IDLE request.
01	OFF	ON	WDTi_FCLK is not shut down on a PRCM IDLE request; only WDTi_ICLK is concerned.
10	ON	OFF	WDTi_ICLK is not shut down on a PRCM IDLE request; only WDTi_FCLK is concerned.
11	ON	ON	None of the clocks are shut down. Therefore, the WDT can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.

#### CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the WDT CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the WDT is disabled in both the CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the WDT clocks. This can lead to unpredictable behavior.

#### 16.4.2.1.2 Reset and Power Management

The MPU WDT (WDT2) belong to the WKUP power domain. As part of that domain, this WDT is sensitive to a WKUP\_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and WKUP\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

The IVA WDT (WDT3) belongs to the PER power domain. As part of that domain, WDT3 is sensitive to the PER\_RST signal issued by the PRCM module. For further details about the PER power domain implementation and PER\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

---

**Note:** WDT2 is reset on power-on or after a warm reset, and then it starts counting.  
WDT3 is reset either on power-on or after a warm reset, and then it doesn't start counting.

---

### 16.4.2.2 Interrupts

Table 16-61 shows interrupt mapping from the three WDTs to the MPU.

**Table 16-61. WDT Interrupt Names and Processor IRQ Mapping**

Timer	Interrupt Name	Mapping	Comments
MPU WDT	WDT2_IRQ	Not connected	
IWA2 WDT	WDT3_IRQ	M_IRQ_36	IWA2 WDT overflow

## 16.4.3 WDTs Functional Description

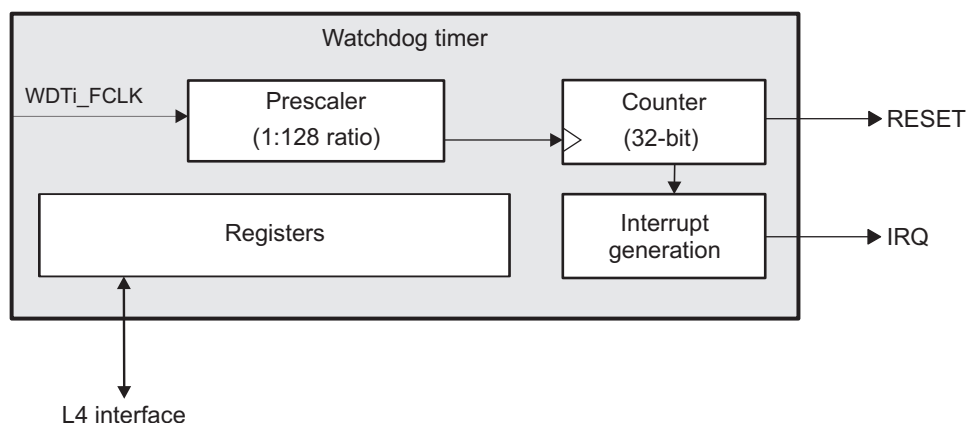

### 16.4.3.1 General WDT Operation

The WDTs are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 16-14. The interrupt generation mechanism is controlled through the WDTi.WIER and WDTi.WISR registers.

The prescaler ratio can be set between 1 and 128 by accessing the WDTi.WCLR[4:2] PTV and WDTi.WCLR[5] PRE fields of the watchdog control register (WDTi.WCLR).

The current timer value can be accessed on-the-fly by reading the WDT counter register (WDTi.WCRR), modified by accessing the WDT load register (WDTi.WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the WDT trigger register (WDTi.WTGR). A start/stop sequence applied to the WDT start/stop register (WDTi.WSPR) can start and stop the WDT.

**Figure 16-16. 32-Bit WDT Functional Block Diagram**

timers-016

### 16.4.3.2 Reset Context

After reset, the WDTs are enabled. Table 16-62 lists the default reset values of the three WDT load registers (WDTi.WLDR) and prescaler ratios (WDTi.WCLR[4:2] PTV field). To get these values, software must read the corresponding WDTi.WCLR[4:2] PTV fields and the 32-bit register to retrieve the static configuration of the module.

**Table 16-62. Count and Prescaler Default Reset Values**

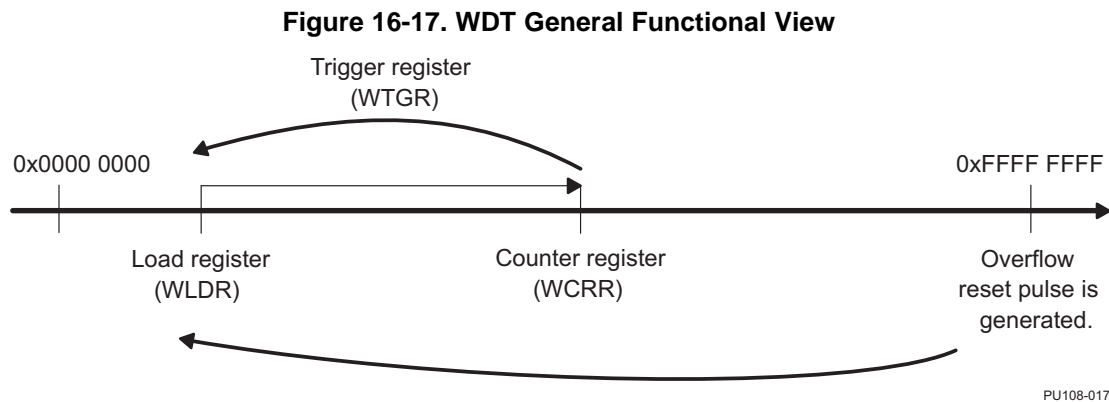

Timer	WLDLR Reset Value	PTV Reset Value
OMAP WDT (WDT2)	0xFFFB 0000	0
IVA2 WDT (WDT3)	0xFFFB 0000	0

**16.4.3.3 Overflow/Reset Generation**

When the WDT counter register (WDTi.WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDTi.WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). Then, after the reset pulse output has been generated, the timer counter begins incrementing again.

Figure 16-17 shows a general functional view of the WDT.

**16.4.3.4 Prescaler Value/Timer Reset Frequency**

Each WDT is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDTi.WCLR[5] PRE bit and the WDTi.WCLR[4:2] PTV field)
- Value loaded into the timer load register (WDTi.WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDTi.WCLR[4:2] PTV field) and is enabled with the WDTi.WCLR[5] PRE bit.

Table 16-63 lists the prescaler clock ratio values.

**Table 16-63. Prescaler Clock Ratios**

PRE Bit (in WDTi.WCLR Register)	PTV Bits (in WDTi.WCLR Register)	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

The watchdog timer overflow rate is expressed by:  $OVF\_Rate = (0xFFFF\ FFFF - WDTn.WLDR + 1) * (wd\text{-}functional\ clock\ period) * PS$

With  $wd\text{-}functional\ clock\ period = 1 / (wd\text{-}functional\ clock\ frequency)$  and  $PS = 2^{(PTV)}$ .

**CAUTION**

Internal resynchronization causes any software write to `GPTn.WSPR` to have some latency before `WSPR` is updated with the programmed value:

$1.5 * functional\ clock\ cycles \leq write\_WSPR\_latency \leq 2.5 * functional\ clock\ cycles$

Remember to take this latency into account whenever the watchdog must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and `WDTi.WCLR[5] PRE bit = 1` (clock divider enabled), the reset period is as listed in [Table 16-64](#).

**Table 16-64. Reset Period Examples**

WDTi.WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

**CAUTION**

- Ensure that the reloaded value allows the correct operation of the application. When a WDT is enabled, the software must periodically trigger a reload before the counter overflows. Hence, the `WDTi.WLDR[31:0]` value must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, `WDTi.WLDR[31:0] = 0xFFFF FFFF` is a special case, although such a `WDTi.WLDR` value is meaningless. When `WDTi.WLDR` is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the WDT is stopped.

[Table 16-65](#) lists the default reset periods for the WDTs.

**Table 16-65. Default WDT Time Periods**

WDTs	Clock Source	Default Reset Period
OMAP/IVA2 WDTs	32 kHz	10 s

**16.4.3.5 Triggering a Timer Reload**

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WDT trigger register (`WDTi.WTGR`) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT trigger register (`WDTi.WTGR`) differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without a reset pulse generation.

The timer counter is loaded with the WDT load register value (the WDTi.WLDR[31:0] TIMER\_LOAD field), and the prescaler is reset.

#### 16.4.3.6 Start/Stop Sequence for WDTs (Using WDTi.WSPR Register)

To start/stop a WDT, access must be made through the start/stop register (WDTi.WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xFFFF AAAA in WDTi.WSPR.
2. Write 0xFFFF 5555 in WDTi.WSPR.

To enable the timer, follow this sequence:

1. Write 0xFFFF BBBB in WDTi.WSPR.
2. Write 0xFFFF 4444 in WDTi.WSPR.

All other write sequences on WDTi.WSPR have no effect on the start/stop feature of the module.

#### 16.4.3.7 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (WDTi.WCRR), prescaler ratio (the WDTi.WCLR[4:2] PTV field), or load value (the WDTi.WLDR[31:0] TIMER\_LOAD field), the WDT must be disabled by using the start/stop sequence (the WDTi.WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (WDTi.WTGR).

#### 16.4.3.8 Watchdog Counter Register Access Restriction (WDTi.WCRR Register)

Because the WDTi.WCRR register is directly related to the timer counter value and is updated on the timer clock (WDTi\_FCLK), a 32-bit shadow register is implemented to read a coherent value of the WDTi.WCRR register. The shadow register is updated by a 16-bit LSB read command.

---

**Note:** Although the L4 clock (WDTi\_ICLK) is completely asynchronous with the timer clock (WDTi\_FCLK), some synchronization is done to ensure that the WDTi.WCRR value is not read while it is being incremented.

---

When 32-bit read access is performed, the shadow register is not updated. Read access is made directly from the accessed register.

To ensure that a coherent value is read inside WDTi.WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

#### 16.4.3.9 WDT Interrupt Generation

The WDT issues an overflow interrupt if this interrupt is enabled in the WDT interrupt enable register (WDTi.WIER[0] OVF\_IT\_ENA = 1). When the overflow occurs, the interrupt status bit (the WDTi.WISR[0] OVF\_IT\_FLAG bit) is set to 1. The output interrupt line (WDTi\_IRQ) is asserted (active low) when both status (OVF\_IT\_FLAG) and enable (OVF\_IT\_ENA) flags are set to 1; the order is not relevant. Writing 1 in the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status after). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDTi.WISR register. Reading the WDTi.WISR register and writing the value back allows a fast acknowledge interrupt process.

---

**Note:** Writing 0 in the WDTi.WISR[0] OVF\_IT\_FLAG bit has no effect on it.

---

Because the interrupt event is generated on the functional clock domain (WDTi\_FCLK), during the interrupt status register (WDTi.WISR) update, the two clock domains are resynchronized.

#### 16.4.3.10 WDT Under Emulation

During emulation mode, the WDT can/cannot continue running, according on the value of the WDTi.WD\_SYSCONFIG[5] EMUFREE bit of the system configuration register (WDTi.WD\_SYSCONFIG).

- When EMUFREE is 1, WDT execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

## 16.5 Watchdog Timer Register Manual

All registers are 32 bits wide and are accessible through the L4 interface with 16-bit or 32-bit access (read/write).

### 16.5.1 Instance Summary

Table 16-66 lists the base address and address space for the WDT module instances. All timers are memory mapped to the L4 peripheral bus memory space.

**Table 16-66. WDT Instance Summary**

Module Name	Base Address	Size
WDTIMER2	0x4831 4000	4K bytes
WDTIMER3	0x4903 0000	4K bytes

### 16.5.2 WDT Register Mapping Summary

#### CAUTION

The WDT registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 16-67 lists the WDT2 registers and Table 16-68 lists the WDT3 registers.

**Table 16-67. WDTIMER2 Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	WDTIMER2 Physical Address

## 16.6 32-kHz Synchronized Timer

### 16.6.1 32-kHz Sync Timer Functional Description

The 32-kHz sync timer is a 32-bit counter, clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (`sys_nrespwron`) primary I/O is active (main device reset). When `sys_nrespwron` is released (on the rising edge of `sys_nrespwron`), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again. Figure 16-18 shows the block diagram of the 32-kHz sync timer.

**Note:** `sys_nrespwron` is an active low I/O.

**Figure 16-18. 32-kHz Sync Timer Block Diagram**

#### 16.6.1.1 Reading the 32-kHz Sync Timer

The sync counter register is 32 bits wide and for correct count capture must be accessed as 16-bit LSB access first and two 16-bit MSB access last. Internal synchronization logic allows reading of the counter value while the counter is running. The time latency to read the counter is one L4 interconnect clock period.

#### 16.6.1.2 32-kHz Sync Timer Features

The following are the main features of the 32-kHz sync timer controller:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0, highest value reached (0xFFFF FFFF)
- On-the-fly read (while counting)

### 16.6.2 32-kHz Sync Timer Environment

The sync timer is accessible only through the L4 interface.

### 16.6.3 32-kHz Sync Timer Integration

#### 16.6.3.1 Clocking, Reset, and Power-Management Scheme

Table 16-91 lists the power and reset domain and the source clock for the 32-kHz sync timer in the device. For more information on power, reset, and clock control and domains, see [Chapter 4, Power, Reset, and Clock Management](#).

**Table 16-91. Clock, Power, and Reset Domains for 32-kHz Sync Timer**

Timer	Source Clock	Interface Clock	Clock and Power Domain	Reset Domain
32-kHz sync timer	sys_32k	32KSYNC_ICLK	WKUP	SYNCT_RST <sup>(1)</sup>

#### 16.6.3.2 Interrupts

The 32-kHz sync timer has no interrupt outputs.

#### 16.6.3.3 Sync Timer 32k and MSuspend Signal

By default, the Sync Timer 32k is not stopped when the MPU or DSP is in *halt*. To activate its sensitivity to the MSuspend signal, the CONTROL.CONTROL\_MSUSPEND\_2[29:27] SyncTMMsctrl bit has been added to the system control module.

## 16.7 32-kHz Sync Timer Register Manual

### 16.7.1 32-kHz Sync Timer Instance Summary

Table 16-92 lists the base address and block size for the 32-kHz sync timer. It is memory mapped to the L4 peripheral bus memory space.

**Table 16-92. 32-kHz Sync Timer Instance Summary**

Module Name	Base Address	Size
32-kHz Sync Timer	0x4832 0000	4K bytes

### 16.7.2 32-kHz Sync Timer Register Mapping Summary

**CAUTION**

The 32-kHz sync timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 16-93 lists the 32-kHz sync timer registers. Table 16-94 through Table 16-98 describe the register bits.

**Table 16-93. 32-kHz Sync Timer Register Summary**

## **UART/IrDA/CIR**

---

---

---

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module on the OMAP34xx multimedia device.

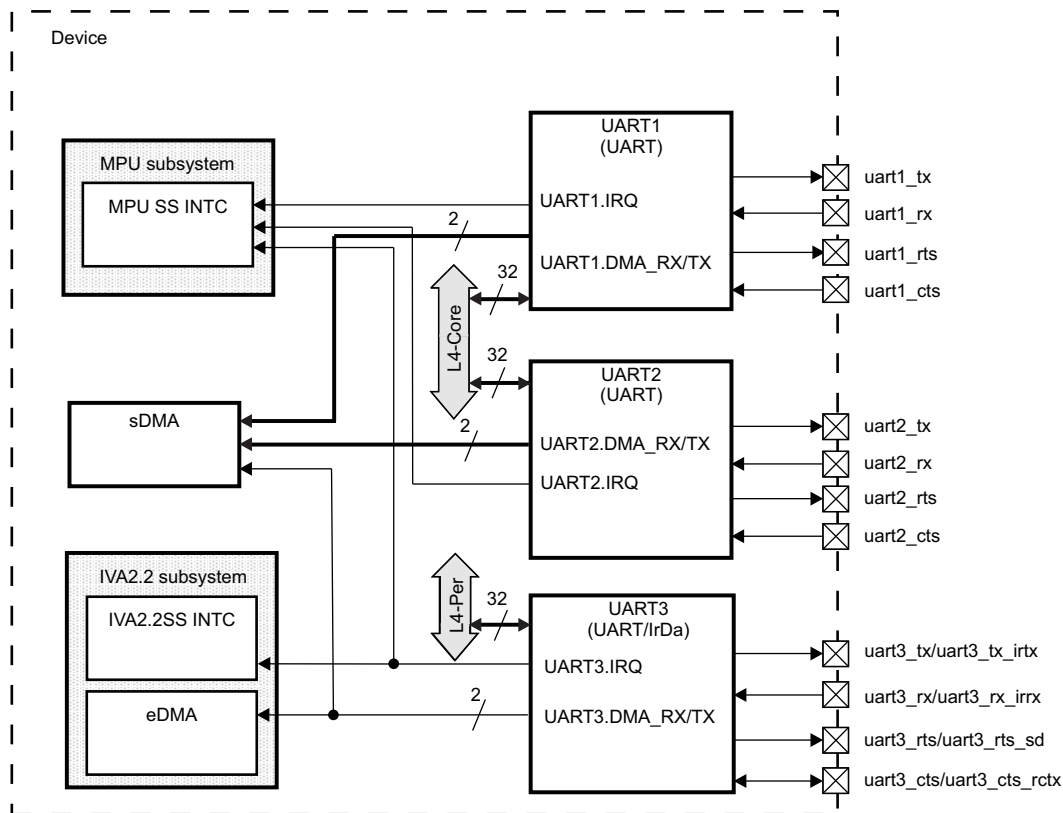

<b>Topic</b>	<b>Page</b>
<b>17.1 UART/IrDA/CIR Overview .....</b>	<b>2575</b>
<b>17.2 UART/IrDA/CIR Environment .....</b>	<b>2579</b>
<b>17.3 UART/IrDA/CIR Integration .....</b>	<b>2592</b>
<b>17.4 UART/IrDA/CIR Functional Description .....</b>	<b>2596</b>
<b>17.5 UART/IrDA/CIR Basic Programming Model .....</b>	<b>2626</b>
<b>17.6 UART/IrDA/CIR Register Manual .....</b>	<b>2634</b>

## 17.1 UART/IrDA/CIR Overview

The OMAP34xx multimedia device contains three universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see Figure 17-1):

- Two UART-only modules, UART1 and UART2, are pinned out for use as UART devices only. UART1 and UART2 must be programmed by setting the UARTi.MDR1\_REG[2:0] MODE\_SELECT field to one of the three UART operating modes.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

**Figure 17-1. UART Module**

uart-001

### 17.1.1 UART Features

The UARTs (UART1, UART2, and UART3 when in UART mode) include the following key features:

- 16C750 compatibility
- 64-byte FIFO for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is either:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6M bits/s. [Table 17-1](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

**Table 17-1. UART Mode Baud Rates, Divisor Values, and Error Rates**

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

### 17.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

[Table 17-2](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

**Table 17-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates**

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16

**Table 17-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates (continued)**

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM <sup>(1)</sup>	1	0

<sup>(1)</sup> PPM = pulse-position-modulation

### 17.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

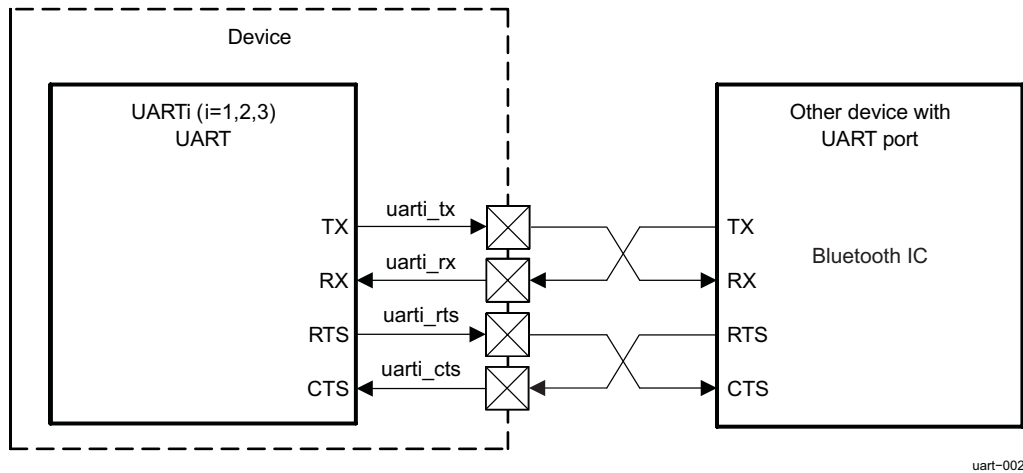

## 17.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

### 17.2.1 System Using UART Communication with Hardware Handshake

UART1, UART2, or UART3 can be connected easily to the UART port of an external IC (see [Figure 17-2](#)).

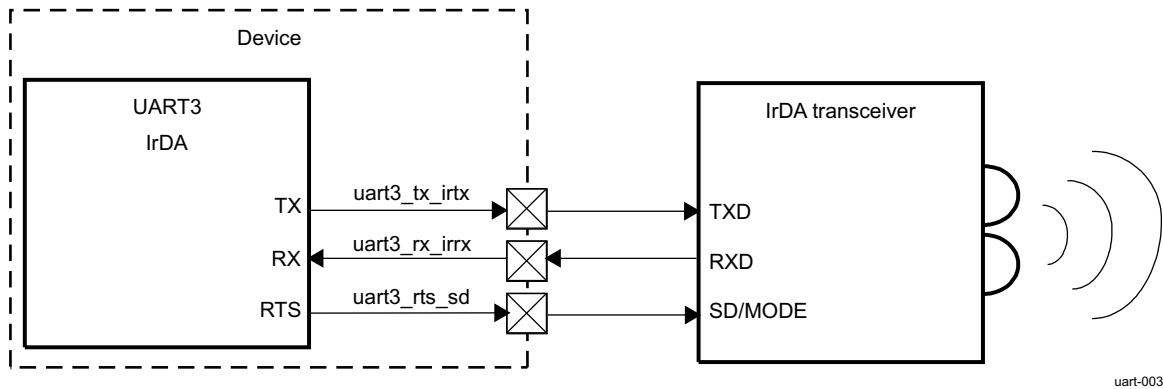

Figure 17-2. UART Mode Bus System Overview

### 17.2.2 System Using IrDA Communication Protocol

As [Figure 17-3](#) shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

Figure 17-3. IrDA System Overview

### 17.2.3 System Using CIR Communication Protocol with Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see [Figure 17-4](#)).

**Figure 17-4. CIR System Overview**

### 17.2.4 UART Interface Description

#### 17.2.4.1 UART Interface Description

[Table 17-3](#) describes the UART interface.

**Table 17-3. UART I/O Pin Description**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>UART Modem Signals</b>			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output	0
		Because this pin is active high in the IrDA mode and the output is muxed, this pin is set to low on reset (when UARTi.MDR1_REG[2:0] is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how UARTi.MDR1_REG is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	
uarti_cts	I	Clear to send	0
		Active-low modem status signal. Reading the UARTi.MSR_REG[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.MSR_REG[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	
uarti_rts	O	Request to send	0
		When active (low), the module is ready to receive data. Setting the UARTi.MCR_REG[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.MCR_REG[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	

<sup>(1)</sup> I = Input, O = Output

#### 17.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x mode ( $\leq 230.4\text{K bits/s}$ )
- UART 16x mode with autobauding ( $\geq 1200\text{ bits/s}$  and  $\leq 115.2\text{K bits/s}$ )

- UART 13x mode ( $\geq 460.8\text{K bits/s}$ )

**CAUTION**

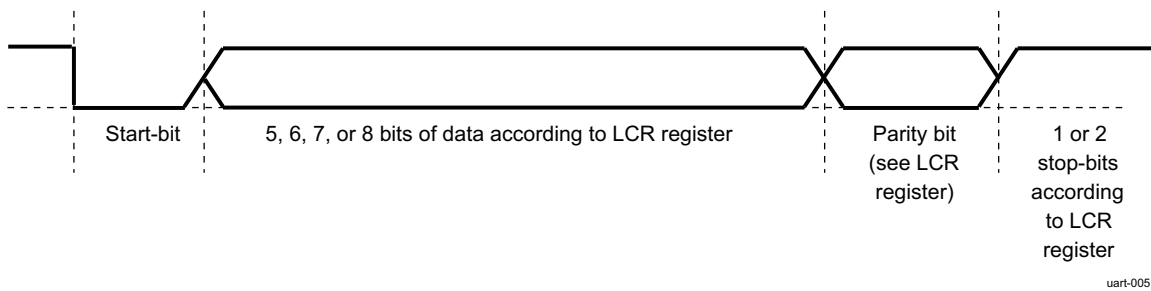

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.MDR1\_REG[2:0] MODE\_SELECT field to select the UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 17-5 shows the UART frame data format.

**Figure 17-5. UART Frame Data Format**

## 17.2.5 IrDA Functional Interfaces

### 17.2.5.1 UART3 Interface Description

Table 17-4 describes the UART3 interface.

**Table 17-4. UART3 I/O Description**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>IrDA Signals</b>			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input, O = Output

### 17.2.5.2 IrDA Protocol and Data Format

#### 17.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start bit, 8 data bits, and 1 stop bit, and is unaffected by the use and settings of the UART3.LCR\_REG register.

The UART3.BLR\_REG[6] XBOF\_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors, such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, and a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR\_REG) to find possible errors of the received frame.

---

**Note:** Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG\_REG[5] DIS\_IR\_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

---

Infrared output in SIR mode can be either 1.6- $\mu$ s or 3/16th encoding, selected by the UART3.ACREG\_REG[7] PULSE\_TYPE bit. In 1.6- $\mu$ s encoding, the infrared pulse width is 1.6  $\mu$ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

---

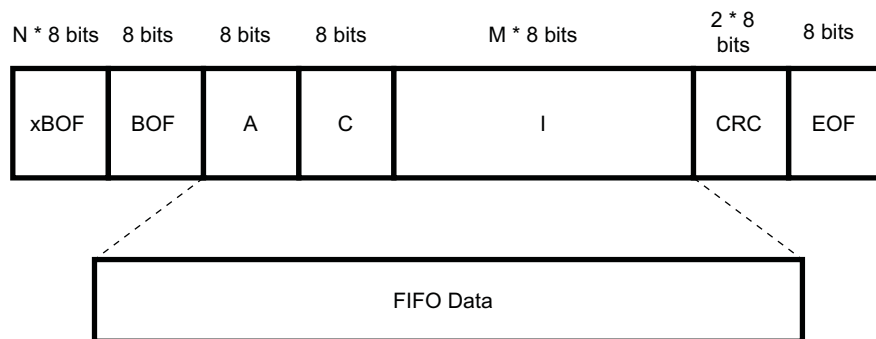

**Note:** Reception supports variable-length stop-bits.

---

### 17.2.5.2.1.1 Frame Format

Figure 17-6 shows the IrDA SIR frame format.

**Figure 17-6. IrDA SIR Frame Format**

uart-006

The CRC is applied on the address (A), control (C), and information (I) bytes.

---

**Note:** The two words of CRC are written to the FIFO in reception.

---

### 17.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)
 The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:
 

For the A, C, I, CRC field:

  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

### 17.2.5.2.1.3 Abort Sequence

The transmitter can decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

### 17.2.5.2.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6- $\mu$ s pulse duration methods. The UART3.ACREG\_REG[7] PULSE\_TYPE bit selects the pulse width method in transmit mode.

### 17.2.5.2.1.5 Encoder

Serial data from the transmit state-machine is encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the `uart3_tx_irtx` line is always low, and the counter used to form a pulse on `uart3_tx_irtx` is cleared continuously.

After the TX FIFO output resets to 0, `uart3_tx_irtx` rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, `uart3_tx_irtx` falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 17-7 shows the IrDA SIR encoding mechanism.

### 17.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 17-8 shows the IrDA SIR decoding mechanism.

**Figure 17-8. IrDA SIR Decoding Mechanism**

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rx_irrx` input can be disabled using the `UART3.ACREG_REG[5]` `DIS_IR_RX` bit. Furthermore, the `UART3.MDR2_REG[6]` `IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IRRX logic inside the UART. This inversion is performed by default.

#### 17.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting `EFR_REG[1:0]` (see Table 17-5), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the `UART3.XON1_ADDR1_REG[7:0]` field and the `UART3.XON2_ADDR2_REG[7:0]` field.

**Table 17-5. EFR\_REG[0-1] IR Address Checking Options**

<code>EFR_REG[1]</code>	<code>EFR_REG[0]</code>	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

#### 17.2.5.2.2 SIR Free Format Mode

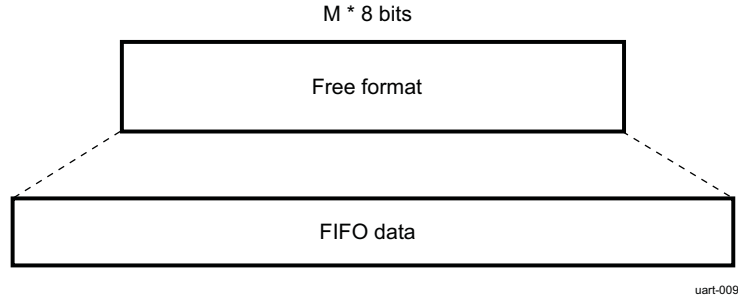

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free format (FF) mode is a subfunction of the existing SIR mode; all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 17-9 shows the SIR free format mode.

**Figure 17-9. SIR Free Format Mode**

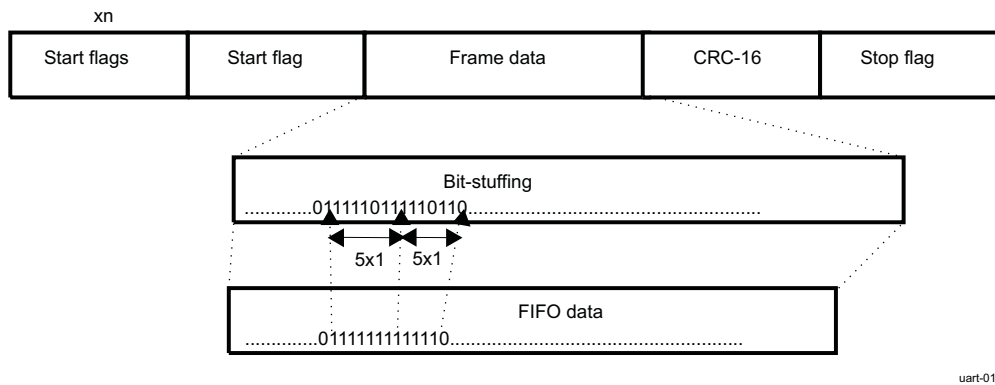

In the SIR free format mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

**17.2.5.2.3 MIR Mode**

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152M bits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag (see Figure 17-10).

**Figure 17-10. MIR Transmit Frame Format**

On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

Contrary to SIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for both start and stop flags (unambiguously, not data, because of bit-stuffing).
- Abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit stuffing).
- Back-to-back frames are allowed with three or more stop flags in between. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR\_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

### 17.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of  $\pm 0.1$  percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 17-11 shows the MIR baud rate adjustment mechanism.

**Figure 17-11. MIR Baud Rate Adjustment Mechanism**

### 17.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

Figure 17-12 shows the SIP.

**Figure 17-12. SIP**

### 17.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4M bits/s. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Table 17-6 shows the FIR transmit frame format.

**Table 17-6. FIR Transmit Frame Format**

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
-------------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 17-7](#)) and generates the SIP (see [Section 17.2.5.2.3.2, SIP Generation](#)).

**Table 17-7. 4-PPM format**

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in [Table 17-7](#) are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 17-8](#)).

**Table 17-8. FIR Preamble, Start Flag, and Stop Flag**

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start Flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop Flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see [Table 17-9](#)).

**Table 17-9. FIR Data Byte Transmission Order Example**

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR\_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

## 17.2.6 CIR Functional Interfaces

### 17.2.6.1 CIR Interface Description

Table 17-10 describes the CIR interface.

**Table 17-10. CIR I/O Description**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>CIR Signals</b>			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input, O = Output

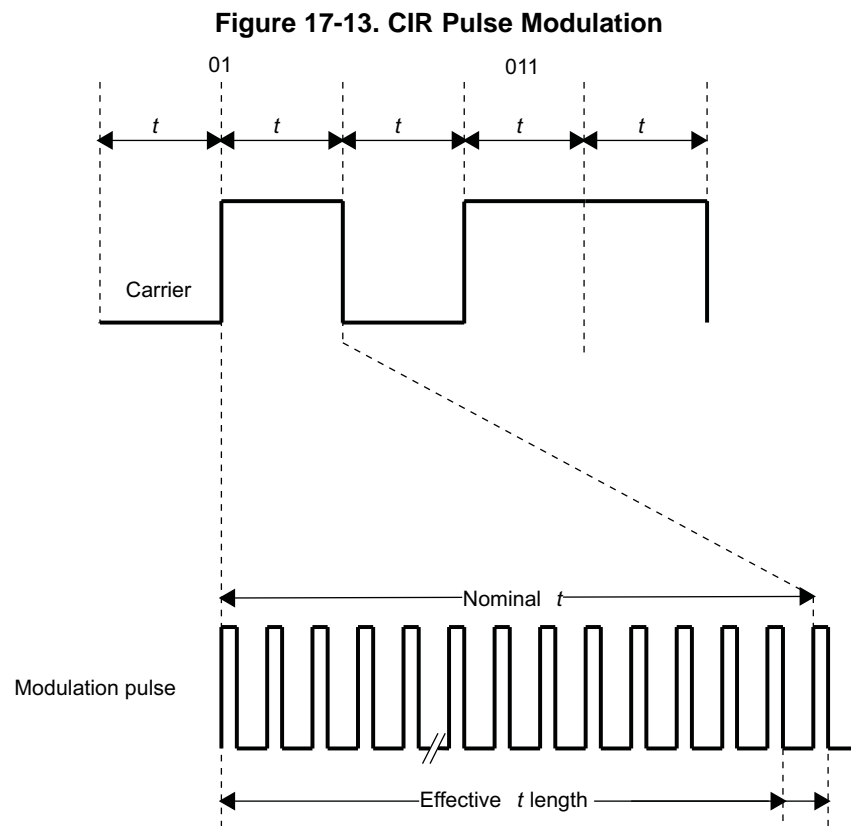

### 17.2.6.2 CIR Protocol and Data Format

In the CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic transmits data packets based on the user-defined frame structure and packet content.

#### 17.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 17-13).

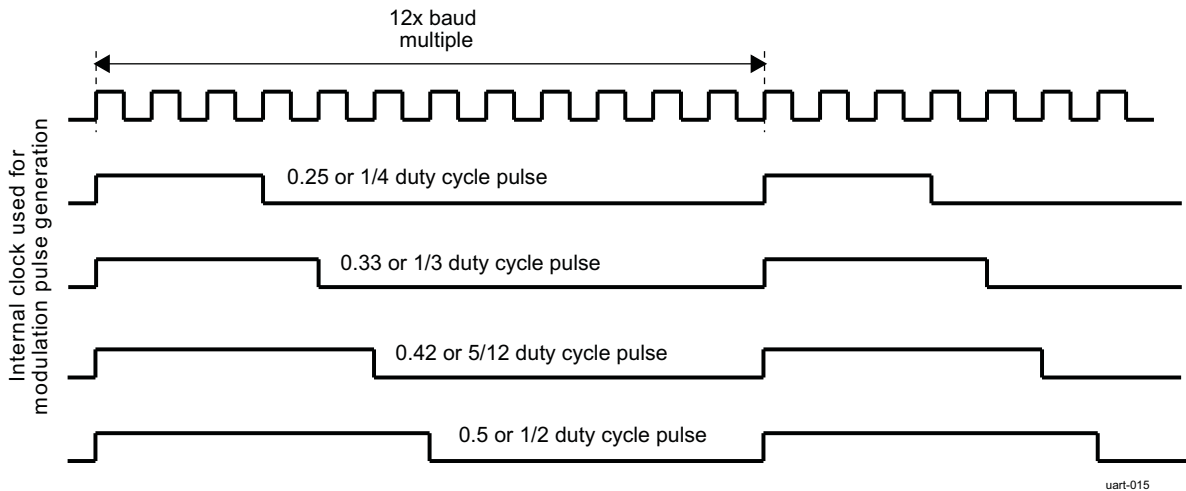

uart-014

### 17.2.6.2.2 Pulse Duty Cycle

The programmer can choose between four possible duty cycles for modulation pulses by setting the appropriate value in the UART3.MDR2\_REG[5:4] CIR\_PULSE\_MODE field (1/4, 1/3, 5/12, or 1/2).

Figure 17-14 shows the CIR modulation duty cycles.

Figure 17-14. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end needs it.

### 17.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote control applications. The first method uses time-extended bit forms (a variable pulse distance, or duration, in which the difference between a logic 1 and logic 0 is the length of the pulse width).

The second encoding method uses a biphas in which the encoding of the logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively. Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphas encoding.

The CIR mode uses a completely flexible free-format encoding in which the TX FIFO is transmitted as a modulated pulse with duration T.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 17-15.).

**Figure 17-15. RC-5 Bit Encoding**

Because the CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (that is, multiples of  $T$ ) is the method used to distinguish between 1 and 0. The following SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 17-16 shows SIRC bit encoding.

**Figure 17-16. SIRC Bit Encoding**

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 17-17 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two  $T$  pulses (digital bits) from the TX and RX FIFOs.

Figure 17-17. RC-5 Standard Packet Format

uart-018

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits inside the standard frame length varies.

Figure 17-18 shows the packet format and bit encoding. As Figure 17-19 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 17-18. SIRC Packet Format

uart-019

**Note:** The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 17-19. SIRC Bit Transmission Example

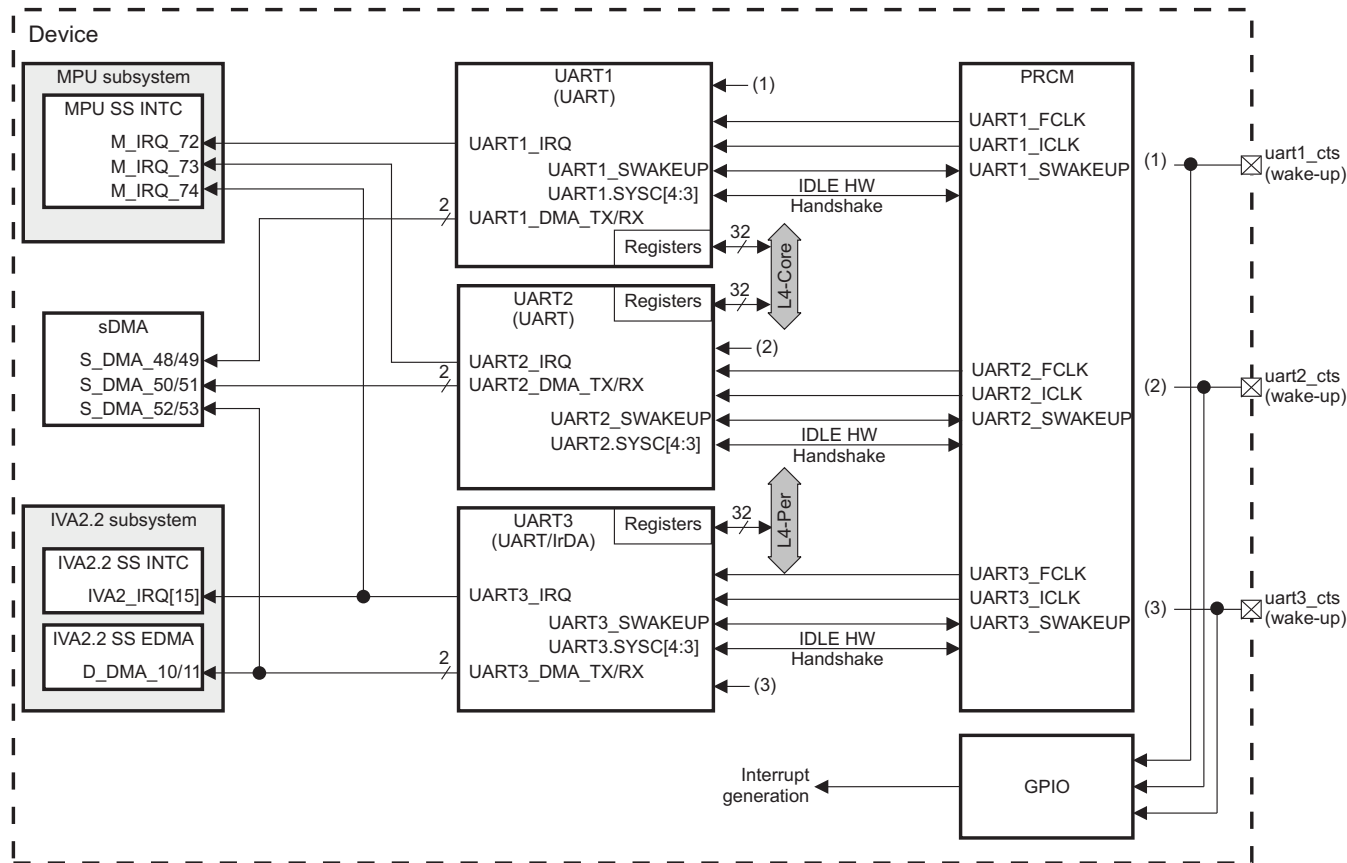

uart-020

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

### 17.3 UART/IrDA/CIR Integration

Figure 17-20 shows the OMAP34xx internal connections with related modules for UART functions.

Figure 17-20. UART Functional Integration

#### 17.3.1 Clocking, Reset, and Power-Management Scheme

##### 17.3.1.1 Clocking

Each UART uses a 48-MHz functional clock for its logic and the generation of external interface signals. Each UART uses an interface clock for register accesses. The power, reset, and clock management (PRCM) module generates and controls all these clocks (for more information, see Chapter 4, Power, Reset, and Clock Management).

Table 17-11 describes the UART clocks.

Table 17-11. UART Clocks

Clock Type	Frequency	Name	Comments
<b>UART1</b>			
Functional clock	CORE_48M_FCLK	UART1_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[13] EN_UART1 bit.
Interface clock	CORE_L4_ICLK	UART1_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[13] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[13] AUTO_UART1 bit.

**Table 17-11. UART Clocks (continued)**

Clock Type	Frequency	Name	Comments
<b>UART2</b>			
Functional clock	CORE_48M_FCLK	UART2_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[14] EN_UART2 bit.
Interface clock	CORE_L4_ICLK	UART2_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[14] EN_UART2 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[14] AUTO_UART2 bit.
<b>UART3</b>			
Functional clock	PER_48M_FCLK	UART3_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[11] EN_UART3 bit.
Interface clock	PER_L4_ICLK	UART3_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN_PER[11] EN_UART3 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_PER[11] AUTO_UART3 bit.

The idle and wake-up processes use a handshake protocol between the PRCM module and the UARTs (for a description of the protocol, see [Chapter 4, Power, Reset, and Clock Management](#)). The UARTi.SYSC\_REG[4:3] IDLEMODE field controls the UART idle mode.

### 17.3.1.2 Hardware Reset

[Table 17-12](#) lists the UART reset domain.

**Table 17-12. Reset Domain**

Peripherals	Reset Domain
UART1	CORE_RST
UART2	CORE_RST
UART3	PER_RST

### 17.3.1.3 Software Reset

The UARTi.SYSC\_REG[1] SOFTRESET bit controls the software reset; writing 1 to this bit triggers a software-reset functionally equivalent to hardware reset.

### 17.3.1.4 Power Domain

Each UART in the CORE or PER power domain can dynamically switch between available voltage levels (see [Table 17-13](#)).

**Table 17-13. Power Domain**

Peripherals	Power Domain
UART1	CORE
UART2	CORE
UART3	PER

## 17.3.2 Hardware Requests

### 17.3.2.1 Interrupts

Table 17-14 describes the UART interrupt mappings.

**Table 17-14. Interrupt Mapping to MPU Subsystem**

IRQ	Source	Description
M_IRQ_72	UART1_IRQ	UART module 1 interrupt to MPU
M_IRQ_73	UART2_IRQ	UART module 2 interrupt to MPU
M_IRQ_74	UART3_IRQ	UART module 3 interrupt to MPU

**Table 17-15. Interrupt Mapping to IVA2.2 Subsystem**

IRQ	SOURCE	DESCRIPTION
IVA2_IRQ[15]	UART3_IRQ	UART module 3 interrupt to IVA2.2 subsystem

### 17.3.2.2 DMA Requests

Table 17-16 describes the UART DMA requests.

**Table 17-16. UART DMA Requests to System DMA**

DMA <sup>(1)</sup>	Source	Description
S_DMA_48	UART1_DMA_TX	UART module 1 transmit request
S_DMA_49	UART1_DMA_RX	UART module 1 receive request
S_DMA_50	UART2_DMA_TX	UART module 2 transmit request
S_DMA_51	UART2_DMA_RX	UART module 2 receive request
S_DMA_52	UART3_DMA_TX	UART module 3 transmit request
S_DMA_53	UART3_DMA_RX	UART module 3 receive request

<sup>(1)</sup> This table assumes that DMA mode 1 is used.

**Table 17-17. UART DMA Requests to IVA2.2 Subsystem DMA**

DMA	SOURCE	DESCRIPTION
D_DMA_10	UART3_DMA_TX	UART module 3 transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 receive request

### 17.3.2.3 Wake-up Request

The UART can wake up the system on different events (see [Section 17.6, UART/IrDA/CIR Register Manual](#)).

One important wake-up generation is event detection on the uarti\_cts pin when the system is idle. The uarti\_cts pin uses an asynchronous path to transmit the wake-up request to the system (PRCM), which enables wake-up capabilities to be active even if all module clocks are off (see [Table 17-18](#)).

**Table 17-18. Wake-Up Requests from PRCM**

Wake-Up Pin	PRCM Input	Description
uart1_cts	UART1_SWAKEUP	Wake UART1 (system wake-up capabilities)

**Table 17-18. Wake-Up Requests from PRCM (continued)**

Wake-Up Pin	PRCM Input	Description
uart2_cts	UART2_SWAKEUP	Wake UART2 (system wake-up capabilities)
uart3_cts	UART3_SWAKEUP	Wake UART3 (system wake-up capabilities)

**CAUTION**

UARTs are not in the WAKEUP power domain, which implies limitations on wake-up capability. If the CORE power domain is off, UART1 and UART2 cannot wake up the system, because power is not supplied. If the PER power domain is off, UART3 cannot wake up the system, because power is not supplied. In these cases, a GPIO multiplexed on the uarti\_cts pin can be used to capture the event and wake up the system. Software must enable this strategy, if required. See [Chapter 25, General-Purpose Interface](#), for a full description of this mechanism.

## 17.4 UART/IrDA/CIR Functional Description

### 17.4.1 UART/IrDA/CIR Block Description

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two mode selections:

- Function mode selection: Route the data to the chosen functionality (UART, IrDA, or CIR) and enable the mechanism corresponding to the chosen functionality.
- Register mode selection, which enables conditional access to registers

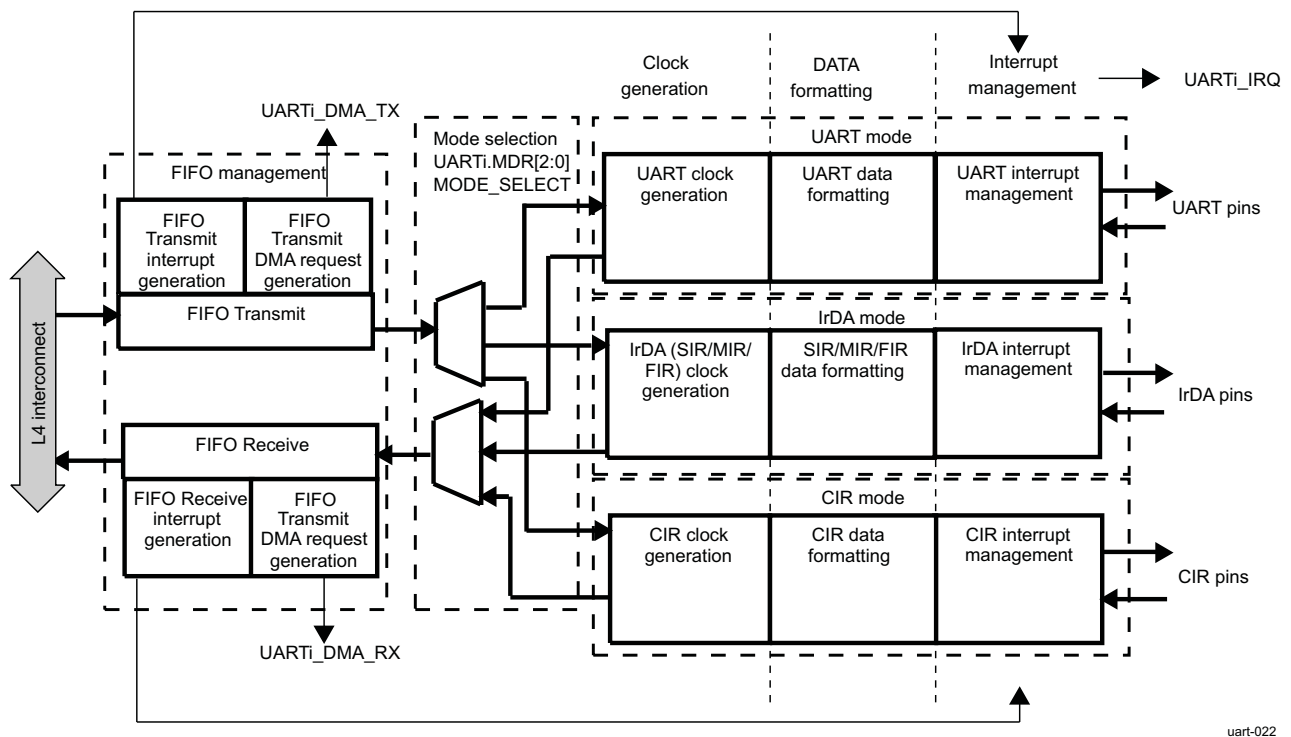

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine, which assumes the transition between FIFO data and frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 17-21 is the UART/IrDA/CIR block diagram.

**Figure 17-21. UART/IrDA/CIR Block Diagram**

uart-022

### 17.4.2 FIFO Management

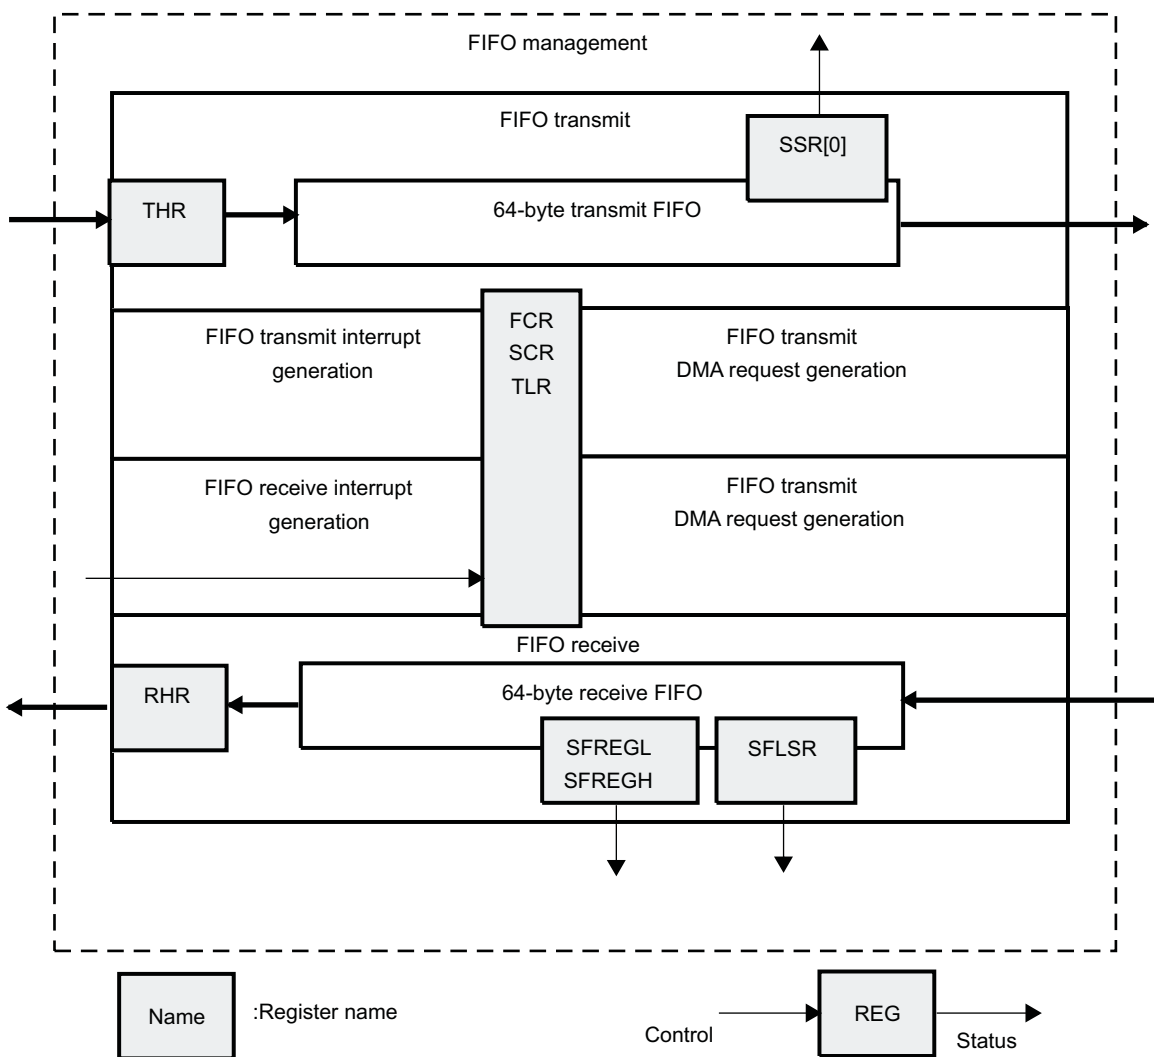

The FIFO is accessed by reading/writing the UARTi.RHR\_REG and UARTi.THR\_REG registers. Parameters are controlled using the FIFO control register (UARTi.FCR\_REG) and supplementary control register (UARTi.SCR\_REG). Reading the UARTi.SSR\_REG[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

The UARTi.TLR\_REG register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. Figure 17-22 shows the FIFO management registers.

**Note:** Data in the UARTi.RHR\_REG register is not overwritten when an overflow occurs.

**Note:** The UARTi.SFLSR\_REG, UARTi.SFREGL\_REG, and UARTi.SFREGH\_REG status registers are used in IrDA mode only. For use, see Section 17.4.4.2.3, IrDA Data Formatting.

Figure 17-22. FIFO Management Registers

uart-023

## 17.4.2.1 FIFO Trigger

### 17.4.2.1.1 Transmit FIFO Trigger

Table 17-19 summarizes the transmit FIFO trigger level settings.

**Table 17-19. TX FIFO Trigger Level Setting Summary**

SCR_REG[6]	TLR_REG[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field (8,16, 32, or 56 spaces)
0	≠ 0x0	Defined by the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space)  <b>Note:</b> The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

### 17.4.2.1.2 Receive FIFO Trigger

Table 17-20 summarizes the receive FIFO trigger level settings.

**Table 17-20. RX FIFO Trigger Level Setting Summary**

SCR_REG[7]	TLR_REG[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field (8,16, 56, or 60 characters)
0	≠ 0x0	Defined by UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character).  <b>Note:</b> The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.TCR\_REG[7:4] RX\_FIFO\_TRIG\_START and UARTi.TCR\_REG[3:0] RX\_FIFO\_TRIG\_HALT fields.

- Trigger levels from 0 to 60 bytes are available with a granularity of four. (Trigger level = 4 x [4-bit register value])
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.
- In the FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the receive FIFO trigger level (either the UARTi.TCR\_REG[7:4] RX\_FIFO\_TRIG\_START field or the UARTi.FCR\_REG[7:6] RX\_FIFO\_TRIG field); otherwise, FIFO operation stalls. In the FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

## 17.4.2.2 FIFO Interrupt Mode

In the FIFO interrupt mode (the FIFO control register UARTi.FCR\_REG[0] FIFO\_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.IER\_REG register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (the UARTi.TLR\_REG[7:4] RX\_FIFO\_TRIG\_DMA and UARTi.TLR\_REG[3:0] TX\_FIFO\_TRIG\_DMA fields or the UARTi.FCR\_REG[7:6] RX\_FIFO\_TRIG and UARTi.FCR\_REG[5:4] TX\_FIFO\_TRIG fields, respectively) is reached.

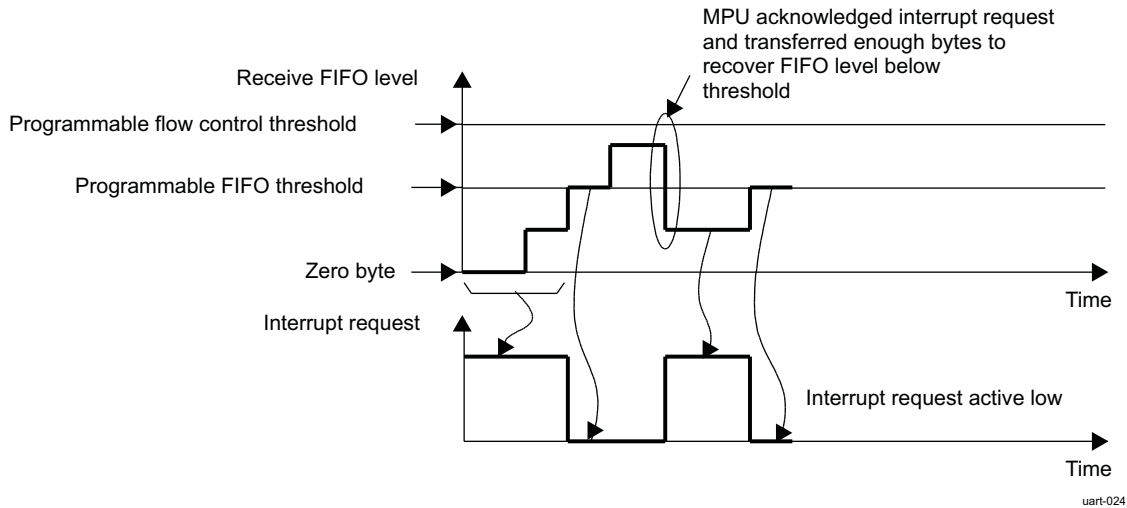

The interrupt signals instruct the MPU to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode).

When the UART flow control is enabled with the interrupt capabilities, the UART flow control FIFO threshold (UARTi.TCR\_REG[3:0] RX\_FIFO\_TRIG\_HALT field) must be greater than or equal to the receive FIFO threshold.

Figure 17-23 shows the generation of the receive FIFO interrupt request.

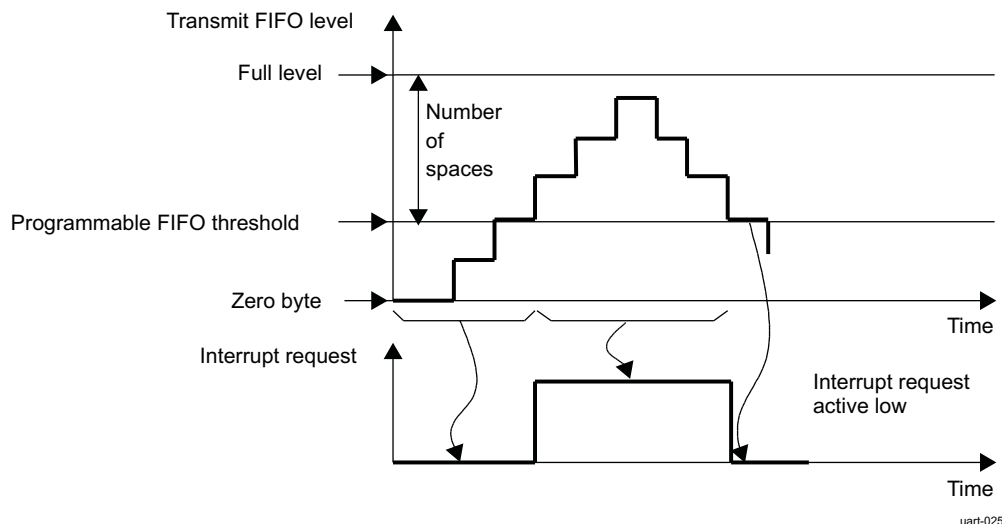

**Figure 17-23. Receive FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 17-24 shows the generation of the transmit FIFO interrupt request.

**Figure 17-24. Transmit FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

### 17.4.2.3 FIFO Polled Mode Operation

In the FIFO polled mode (the UARTi.FCR\_REG[0] FIFO\_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.IER\_REG register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.LSR\_REG).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

### 17.4.2.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in [Table 17-16](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

The DMA requests in mode 2 and mode 3 use S\_DMA\_48, S\_DMA\_50, and S\_DMA\_52/D\_DMA\_10. S\_DMA\_49, S\_DMA\_51, and S\_DMA\_53/D\_DMA\_11 are not used by the module in mode 2 and mode 3 and can be selected as follows:

- When the UARTi.SCR\_REG[0] DMA\_MODE\_CTL bit is set to 0, setting the UARTi.FCR\_REG[3] DMA\_MODE bit to 0 enables DMA mode 0. Setting the DMA\_MODE bit to 1 enables DMA mode 1.
- When the DMA\_MODE\_CTL bit is set to 1, the UARTi.FCR\_REG[2:1] DMA\_MODE\_2 field determines DMA mode 0 to 3 based on the supplementary control register (SCR\_REG) description.

For example:

- If no DMA operation is desired, set the DMA\_MODE\_CTL bit to 1 and the DMA\_MODE\_2 field to 0x0. (The DMA\_MODE bit is discarded.)
- If DMA mode 1 is desired, set either the DMA\_MODE\_CTL bit to 0 and the DMA\_MODE bit to 1, or set the DMA\_MODE\_CTL bit to 1 and the DMA\_MODE\_2 field to 01. (The DMA\_MODE bit is discarded.)

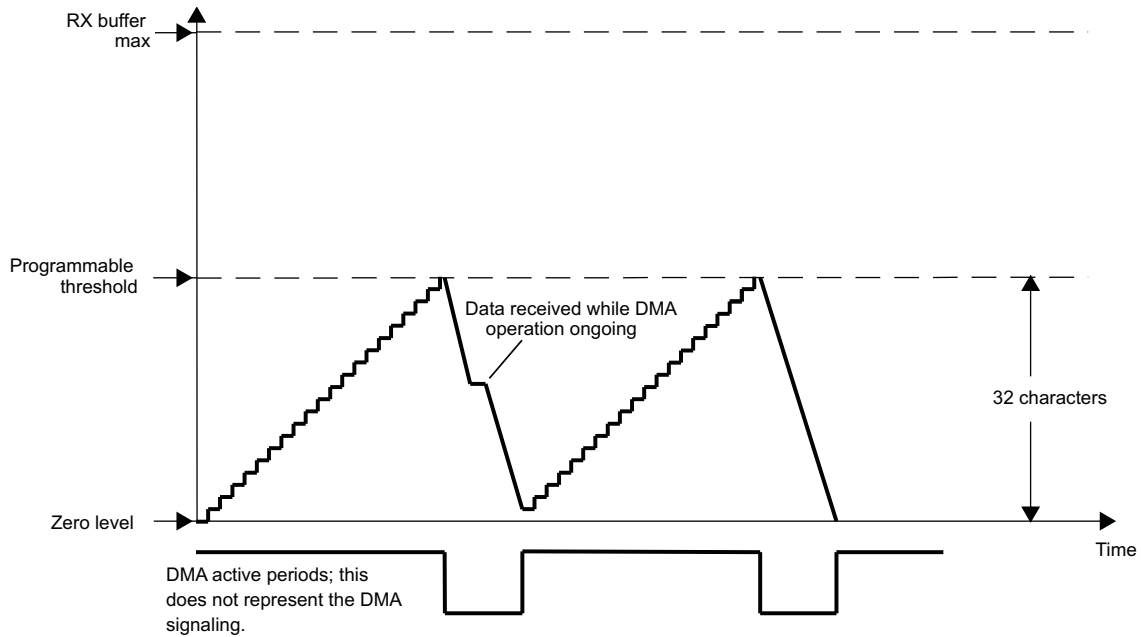

If the FIFOs are disabled (the UARTi.FCR\_REG[0] FIFO\_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

17.4.2.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 17-25 through Figure 17-28 show the supported DMA operations.

Figure 17-25. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the receive FIFO reaches its threshold level defined in the trigger level register (UARTi.TLR\_REG). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UARTi.TLR\_REG) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

**Figure 17-26. Transmit FIFO DMA Request Generation (56 Spaces)**

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the `UARTi.TLR_REG` register.

The threshold can be programmed in a number of ways. [Figure 17-26](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the `UARTi.FCR_REG[5:4]` `TX_FIFO_TRIG` field or the `UARTi.TLR_REG[3:0]` `TX_FIFO_TRIG_DMA` field concatenated with the `TX_FIFO_TRIG` field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

[Figure 17-27](#) shows an example with eight spaces to show the buffer level crossing the space threshold. Again, the local host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

**Figure 17-27. Transmit FIFO DMA Request Generation (8 Spaces)**

uart-028

The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 17-28](#)). The buffer is filled at a faster rate than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.DLL\_REG and the UARTi.DLH\_REG registers.

Again, the DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

**Figure 17-28. Transmit FIFO DMA Request Generation (1 Space)**

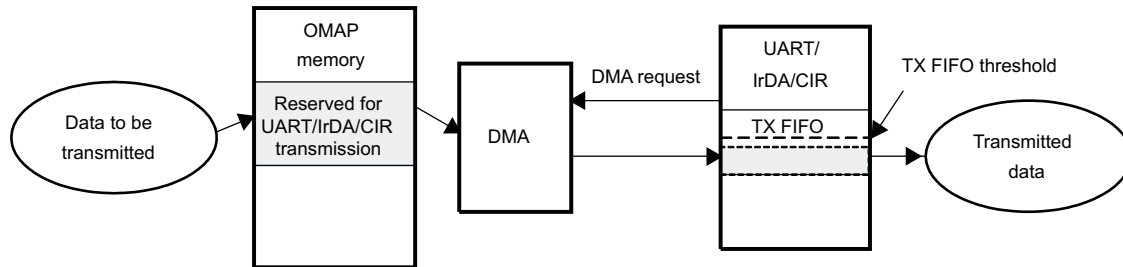

uart-029

### 17.4.2.4.2 DMA Transmission

Figure 17-29 shows the DMA transmission process.

**Figure 17-29. Transmission Process**

uart-030

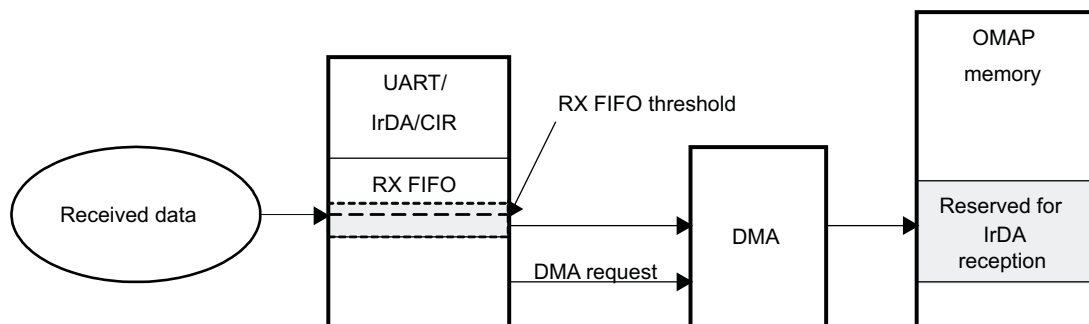

- Data to be transmitted are put in the OMAP34xx memory reserved for UART/IrDA/CIR transmission by the DMA:
  - Until the TX FIFO trigger level is not reached, a DMA request is generated.
  - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR\_REG empty (TX FIFO empty).

**Note:** In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR\_REG register empties.

### 17.4.2.4.3 DMA Reception

Figure 17-30 shows the DMA reception process.

**Figure 17-30. Reception Process**

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
  - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

### 17.4.3 Mode Selection

#### 17.4.3.1 Register Access Modes

##### 17.4.3.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Both configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only in the initialization step or reconfiguration of the module.

The value of the UARTi.LCR\_REG register determines the register access mode (see [Table 17-21](#)).

**Table 17-21. UART/IrDA/CIR Register Access Mode Programming (Using LCR\_REG)**

Mode	Condition
Configuration_mode_A	LCR_REG[7] = 0x1 and LCR_REG[7:0]! = 0xBF
Configuration_mode_B	LCR_REG[7] = 0x1 and LCR_REG[7:0] = 0xBF
Operational_mode	LCR_REG[7] = 0x0

##### 17.4.3.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional to the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Section 17.6](#), *UART/IrDA/CIR Register Manual*.

[Table 17-22](#) through [Table 17-24](#) summarize the register access submodes.

**Table 17-22. Sub-Configuration\_Mode\_A Mode Summary**

Mode	Condition
MSR_SPR	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

**Table 17-23. Sub-Configuration\_Mode\_B Mode Summary**

Mode	Condition
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1
XOFF	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)

**Table 17-24. Sub-Operational\_Mode Mode Summary**

Mode	Condition
MSR_SPR	EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

### 17.4.3.1.3 Registers Available for the Register Access Modes

Table 17-25 lists the names of the register hits in each access register mode. Gray-shaded registers do not depend on the register access mode (available in all modes).

**Table 17-25. UART/IrDA/CIR Register Access Mode Overview**

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write

(1) if MSR\_SPR mode is active (see Section 17.4.3.1.2, Register Access Submode)

(2) if TCR\_TLR mode is active (see Section 17.4.3.1.2, Register Access Submode)

(3) if XOFF mode is active (see Section 17.4.3.1.2, Register Access Submode)

### 17.4.3.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.MDR1\_REG[2:0] MODE\_SELECT field (see [Table 17-26](#)).

**Table 17-26. UART Mode Selection**

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE\_SELECT is effective when the module is in operational mode (see [Section 17.4.3.1, Register Access Modes](#)).

#### 17.4.3.2.1 Registers Available for the UART Function

Only the registers listed in [Table 17-27](#) are used for the UART function.

**Table 17-27. UART Mode Register Overview<sup>(1)(2)</sup>**

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write
0x000	DLL_REG	DLL_REG	DLL_REG	DLL_REG	RHR_REG	THR_REG
0x004	DLH_REG	DLH_REG	DLH_REG	DLH_REG	IER_REG(UART)	IER_REG(UART)

## 17.4.4 Protocol Formatting

### 17.4.4.1 UART Mode

#### 17.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 17-31 shows the baud rate generator and associated controls.

#### CAUTION

It is mandatory that `MODE_SELECT = DISABLE` (`UARTi.MDR1_REG[2:0] = 0x7`) before initializing or modifying clock parameter controls (`UARTi.DLH_REG`, `UARTi.DLL_REG`). Failure to observe this rule can result in unpredictable module behavior.

#### 17.4.4.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 17-30 describes the UART baud rate settings.

**Table 17-30. UART Baud Rate Settings (48-MHz Clock)**

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	0x27, 0x10	0.3 Kbps	0
0.6 Kbps	16x	5000	0x13, 0x88	0.6 Kbps	0
1.2 Kbps	16x	2500	0x09, 0xC4	1.2 Kbps	0
2.4 Kbps	16x	1250	0x04, 0xE2	2.4 Kbps	0
4.8 Kbps	16x	625	0x02, 0x71	4.8 Kbps	0
9.6 Kbps	16x	312	0x01, 0x38	9.6153 Kbps	+0.16
14.4 Kbps	16x	208	0x00, 0xD0	14.423 Kbps	+0.16
19.2 Kbps	16x	156	0x00, 0x9C	19.231 Kbps	+0.16
28.8 Kbps	16x	104	0x00, 0x68	28.846 Kbps	+0.16

**Table 17-30. UART Baud Rate Settings (48-MHz Clock) (continued)**

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)
38.4 Kbps	16x	78	0x00, 0x4E	38.462 Kbps	+0.16
57.6 Kbps	16x	52	0x00, 0x34	57.692 Kbps	+0.16
115.2 Kbps	16x	26	0x00, 0x1A	115.38 Kbps	+0.16
230.4 Kbps	16x	13	0x00, 0x0D	230.77 Kbps	+0.16
460.8 Kbps	13x	8	0x00, 0x08	461.54 Kbps	+0.16

1.843 Mbps	13x	2	0x00, 0x02	1.846 Mbps	+0.16
3.6884 Mbps	13x	1	0x00, 0x01	3.6923 Mbps	+0.16

#### 17.4.4.1.3 UART Data Formatting

The UART module can use hardware flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART module is enhanced with the autobauding function. In control mode, autobauding allows the speed, the number of bits per character, and the parity selected to be set automatically.

##### 17.4.4.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.LCR\_REG register.

Character length is specified using the UARTi.LCR\_REG[1:0] CHAR\_LENGTH field.

The number of stop bits is specified using the UARTi.LCR\_REG[2] NB\_STOP register bit.

The parity bit is programmed using the UARTi.LCR\_REG[5:3] PARITY\_EN, PARITY\_TYPE\_1, and PARITY\_TYPE\_2 register bits (see Table 17-31).

**Table 17-31. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE1	PARITY_TYPE2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

##### 17.4.4.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming the UARTi.EFR\_REG[7:6] AUTO\_CTS\_EN and AUTO\_RTS\_EN bits, respectively.

With auto-CTS, uarti\_cts must be active before the module can transmit data.

Auto-RTS activates the uarti\_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti\_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.TCR\_REG register determine the levels at which uarti\_rts is activated/deactivated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

- **Auto-RTS**

Auto-RTS data flow control originates in the receiver block. The receiver FIFO trigger levels used in auto-RTS are stored in the UARTi.TCR\_REG register. uarti\_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.TCR\_REG[3:0] RX\_FIFO\_TRIG\_HALT field. When the receiver FIFO HALT trigger level is reached, uarti\_rts is deasserted. The sending device (for example, another UART) might send an additional byte after the trigger level is reached because it might not recognize the deassertion of RTS until it begins sending the additional byte.

uarti\_rts is automatically reasserted when the receiver FIFO reaches the RESUME trigger level programmed by the UARTi.TCR\_REG[7:4] RX\_FIFO\_TRIG\_START field. This reassertion requests the sending device to resume transmission.

In this case, uarti\_rts is an active-low signal.

- **Auto-CTS**

The transmitter circuitry checks uarti\_cts before sending the next data byte. When uarti\_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti\_cts must be deasserted before the middle of the last stop bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti\_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti\_cts is an active-low signal.

#### 17.4.4.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.EFR\_REG) and the modem control register (UARTi.MCR\_REG). Different combinations of software flow control can be enabled by setting different combinations of UARTi.EFR\_REG[3:0] (see Table 17-32).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.MCR\_REG[5]): Operation resumes after receiving any character after recognition of the XOFF character.

---

**Note:** The XON-any character is written into the RX FIFO even if it is a software flow character.

---

- Special character (UARTi.EFR\_REG[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.IIR\_REG[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.IIR\_REG. The special character is transferred to the RX FIFO.

**Table 17-32. EFR\_REG[0-3] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	Tx, Rx Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

<sup>(1)</sup> In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. XON1 is defined in the UARTi.XON1\_ADDR1\_REG[7:0] XON\_WORD1 field, XON2 is defined in UARTi.XON2\_ADDR2\_REG[7:0] XON\_WORD2. XOFF1 is defined in the UARTi.XOFF1\_REG[7:0] XOFF\_WORD1 field, XOFF2 is defined in UARTi.XOFF2\_REG[7:0] XOFF\_WORD2.

#### 17.4.4.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character is complete. XOFF detection also sets UARTi.IIR\_REG[4] (if enabled by UARTi.IER\_REG[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, UARTi.IIR\_REG[4] is cleared and the XOFF interrupt disappears.

---

**Note:** When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

---

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.EFR\_REG[1:0] = 0x2, if XON1 and XOFF1 characters are received, they do not get written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.EFR\_REG[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 17.4.4.1.3.3.2 Transmit (TX)

XOFF1: Two characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.TCR\_REG[3:0].

XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed by UARTi.TCR\_REG[7:4].

---

**Note:** If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission to proceed.

---

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 17.4.4.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an AT command (ASCII code). These characteristics are used to receive data after an "at" (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UASR\_REG register reflects the correct settings for the baud rate detected. The interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

**Note:** The combination of 7-bit character + space parity is not supported.

---

Autobauding mode is selected when the UARTi.MDR1\_REG[2:0] MODE\_SELECT field is set to 0x2. In the UART autobauding mode, UARTi.DLL\_REG, UARTi.DLH\_REG, UARTi.LCR\_REG[5:0] settings are not used; instead, UASR\_REG is updated with the configuration detected by the autobauding logic.

#### UASR\_REG Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.LCR\_REG, UARTi.DLL\_REG, and UARTi.DLH\_REG registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.MDR1\_REG[2:0] MODE\_SELECT field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1,200 and 115,200 bps (10 possibilities)

#### 17.4.4.1.3.5 Error Detection

When the UARTi.LSR\_REG register is read, UARTi.LSR\_REG[4:2] reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the UARTi.LSR\_REG register and then reading the UARTi.RHR\_REG register identifies errors in a character.

Reading the UARTi.RHR\_REG register updates the BI, FE, and PE bits (see Table 17-33 for the UART mode interrupts).

The UARTi.LSR\_REG [7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

---

**Note:** Reading UARTi.LSR\_REG does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading UARTi.RHR\_REG.

---

Reading UARTi.LSR\_REG clears the OE bit if it is set (see Table 17-33 for the UART mode interrupts).

#### 17.4.4.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with UARTi.IIR\_REG[5:1] IT\_TYPE = 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the system (MPU) must:

- Reset the RX FIFO
- Read the UARTi.RESUME\_REG register (which clears the internal flag)

#### 17.4.4.1.3.7 Time-out and Break Conditions

##### 17.4.4.1.3.7.1 Time-out Counter

An RX idle condition is detected when the receiver line (uarti\_rx) is high for a time equivalent to 4x programmed word length + 12 bits. uarti\_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti\_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti\_rx or when the UARTi.RHR\_REG is read.

##### 17.4.4.1.3.7.2 Break Condition

When a break condition occurs, uarti\_tx is pulled low. A break condition is activated by setting the UARTi.LCR\_REG[6] BREAK\_EN bit. The break condition is not aligned on word stream (that is, a break condition can occur in the middle of a character). The only way to send a break condition on a full character is as follows:

1. Reset the transmit FIFO (if enabled).
2. Wait for the transmit shift register to empty (UARTi.LSR\_REG[6] TX\_SR\_E = 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

#### 17.4.4.1.4 UART Mode Interrupt Management

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.IIR\_REG) sets the UARTi.IIR\_REG[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and provides the type of interrupt through UARTi.IIR\_REG[5:1]. Table 17-33 summarizes the interrupt control functions.

**Table 17-33. UART Mode Interrupts**

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR_REG. OE: Read LSR_REG.
001100	2	RX time-out	Stale data in RX FIFO	Read RHR_REG.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR_REG until interrupt condition disappears.
000010	3	THR interrupt	TFE (THR_REG empty) (FIFO disable)	Write to THR_REG until interrupt condition disappears.

**Table 17-33. UART Mode Interrupts (continued)**

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000000	4	Modem status	TX FIFO below trigger level (FIFO enable) See the <a href="#">MSR_REG</a> register.	Read <a href="#">MSR_REG</a> .
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of <a href="#">IIR_REG</a> , if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read <a href="#">IIR_REG</a> .

For the receiver-line status interrupt, the RX\_FIFO\_STS bit (UARTi.[LSR\\_REG](#)[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.[IIR\\_REG](#) register.

#### 17.4.4.1.4.1 Wake-up Interrupt

Wake-up interrupt is a special interrupt that is not designed the same way as other interrupts. This interrupt is enabled when the UARTi.[SCR\\_REG](#)[4] RX\_CTS\_WU\_EN bit is set to 1. The UARTi.[IIR\\_REG](#) register is not modified when it occurs; the UART3.[SSR\\_REG](#)[1] RX\_CTS\_WU\_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, the only way to clear it is to reset the UARTi.[SCR\\_REG](#)[4] RX\_CTS\_WU\_EN bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

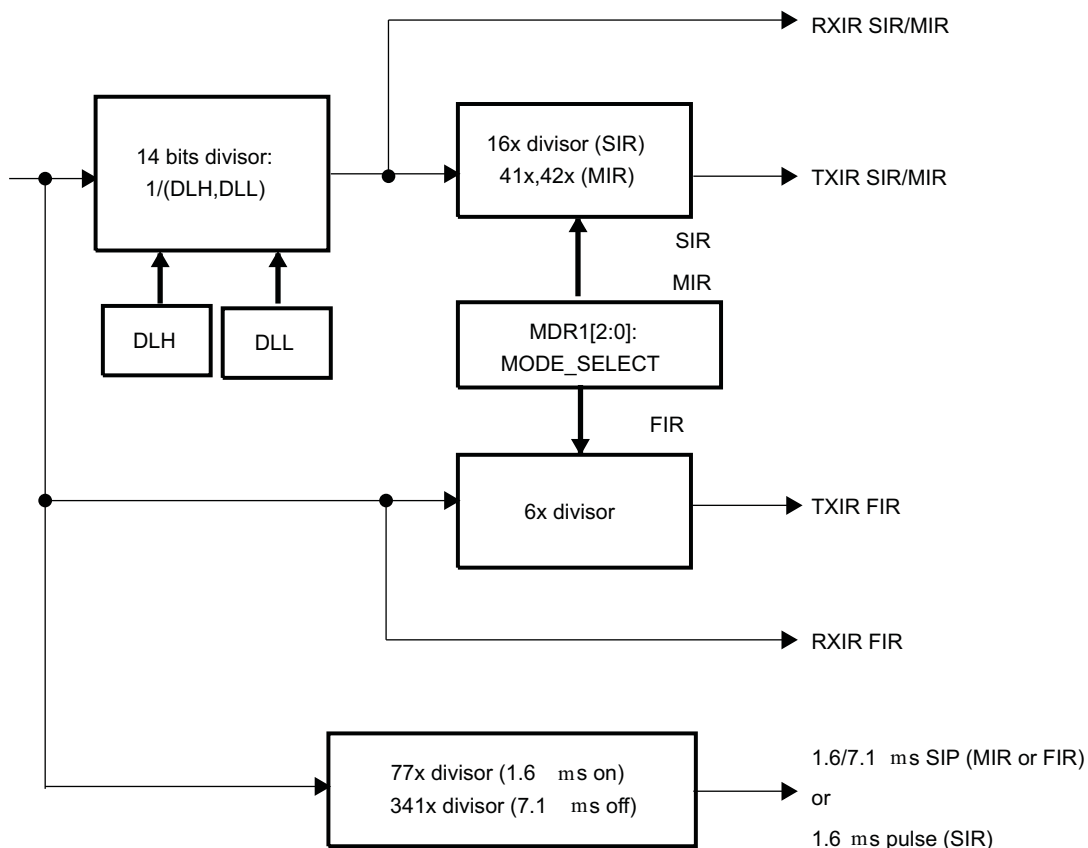

#### 17.4.4.2 IrDA Mode (UART3 Only)

##### 17.4.4.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

[Figure 17-32](#) shows the baud rate generator and associated controls.

Figure 17-32. Baud Rate Generator

uart-033

**CAUTION**

Before trying to initialize or modify clock parameter controls (UARTi.DLH\_REG, UARTi.DLL\_REG), it is mandatory to set MODE\_SELECT=DISABLE (UARTi.MDR1\_REG[2:0]=0x7). Failure to observe this rule can result in unpredictable module behavior.

**17.4.4.2.2 Choosing the Appropriate Divisor Value**

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 17-34 lists the IrDA baud rate settings.

**Table 17-34. IrDA Baud Rates Settings**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)\$	Source Jitter (%)	Pulse duration
2.4 Kbps	SIR	16x	3/16	1250	2.4 Kbps	0	0	78.1 μs
9.6 Kbps	SIR	16x	3/16	312	9.6153 Kbps	+0.16	0	19.5 μs
19.2 Kbps	SIR	16x	3/16	156	19.231 Kbps	+0.16	0	9.75 μs
38.4 Kbps	SIR	16x	3/16	78	38.462 Kbps	+0.16	0	4.87 μs

**Table 17-34. IrDA Baud Rates Settings (continued)**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)\$	Source Jitter (%)	Pulse duration
57.6 Kbps	SIR	16x	3/16	52	57.692 Kbps	+0.16	0	3.25 $\mu$ s
115.2 Kbps	SIR	16x	3/16	26	115.38 Kbps	+0.16	0	1.62 $\mu$ s
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps <sup>(1)</sup>	0	+1.63/- 0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps <sup>(1)</sup>	0	+1.63/- 0.80	208 ns
4 Mbps	FIR	6x	4 PPM	-	4 Mbps	0	0	125 ns

<sup>(1)</sup> Average value

**Note:** Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

### 17.4.4.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

#### 17.4.4.2.3.1 IRRX Polarity Control

The UART3.MDR2\_REG[6] IRRXINVERT bit provides the flexibility to invert the uart3\_rx\_irrx pin in the UART module to ensure that the protocol at the output of the transceiver module has the same polarity at module level. By default, the uart3\_rx\_irrx pin is inverted because most transceivers invert the IR receive pin.

#### 17.4.4.2.3.2 IrDA Reception Control

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3\_rx\_irrx input can be disabled by the UART3.ACREG\_REG[5] DIS\_IR\_RX bit.

#### 17.4.4.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives with the UART3.XON1\_ADDR1\_REG[7:0] XON\_WORD1 and UART3.XON2\_ADDR2\_REG[7:0] XON\_WORD2 fields.

Setting the EFR\_REG[0] bit to 1 selects address1 checking. Setting the EFR\_REG[1] bit to 1 selects address2 checking. Setting the EFR\_REG[1:0] bit to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for both private and public addresses.

If address checking is disabled, all received frames write to the reception FIFO.

#### 17.4.4.2.3.4 Frame Closing

A transmission frame can be correctly terminated in two ways:

- Frame-length method: The frame-length method is selected by setting the UART3.MDR1\_REG[7] FRAME\_END\_MODE bit to 0. The MPU writes the frame-length value to the UART3.TXFLH\_REG and UART3.TXFLL\_REG registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the frame-length value.
- Set-EOT bit method: The set-EOT bit method is selected by setting the FRAME\_END\_MODE bit to 1. The MPU writes 1 to the UART3.ACREG\_REG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

#### 17.4.4.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or a whole frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.ACREG\_REG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.MDR1\_REG[5] SCT bit to 1. This transmission method is different from the normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

#### 17.4.4.2.3.6 Error Detection

When the UART3.LSR\_REG register is read, the UART3.LSR\_REG[4:2] field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (see [Table 17-35](#) for IrDA mode interrupts). STATUS FIFO must be read until empty (a maximum of eight reads is required).

#### 17.4.4.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the system (MPU) must:

- Reset the TX FIFO.
- Read the UART3.RESUME\_REG register (which clears the internal flag).

This functionality can be disabled by the UART3.ACREG\_REG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop bit in transmission if the TX FIFO is empty.

#### 17.4.4.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.4.1.3.6](#), *Overrun During Receive*).

#### 17.4.4.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading UART3.SFREGH\_REG[3:0] (MSB) and UART3.SFREGL\_REG[3:0] (LSB) obtains the frame length. The frame error status is read in the UART3.SFLSR\_REG register. Reading the UART3.SFLSR\_REG register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

#### 17.4.4.2.4 SIR Mode DATA Formatting

This section provides specific instructions for SIR mode programming.

##### 17.4.4.2.4.1 Abort Sequence

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.ACREG\_REG[1] ABORT\_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

#### **CAUTION**

When the transmit FIFO is not empty and the UART3.MDR1\_REG[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.

#### **17.4.4.2.4.2 Pulse Shaping**

The SIR mode supports both the 3/16th or the 1.6- $\mu$ s pulse duration methods. The UART3.ACREG\_REG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

#### **17.4.4.2.4.3 SIR Free Format Programming**

The SIR FF mode is selected by setting the module in the UART mode (UART3.MDR1\_REG[2:0] MODE\_SELECT = 0x0) and the UART3.MDR2\_REG[3] UART\_PULSE bit to 1 to allow pulse shaping.

Because the bit format remains the same, some UART mode configuration registers must be set at specific values:

- UART3.LCR\_REG[1:0] CHAR\_LENGTH field = 0x3 (8 data bits)
- UART3.LCR\_REG[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART3.LCR\_REG[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many of them are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### **17.4.4.2.5 MIR and FIR Mode Data Formatting**

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.LSR\_REG) to detect possible errors in the received frame.

When the UART3.MDR1\_REG[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART3.ACREG\_REG[3] SEND\_SIP bit.

The system (MPU) can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, which can reduce the overhead required.

#### **17.4.4.2.6 IrDA Mode Interrupt Management**

##### **17.4.4.2.6.1 IrDA Interrupts**

The IrDA function generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER\_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR\_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER\_REG and UART3.IIR\_REG mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 17-35](#)). The interrupt line is activated when any of the eight interrupts is generated (there is no priority).

**Table 17-35. IrDA Mode Interrupts**

IIR_REG Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read <a href="#">RHR_REG</a> until interrupt condition disappears.
1	THR interrupt	TFE ( <a href="#">THR_REG</a> empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to <a href="#">THR_REG</a> until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read <a href="#">RHR_REG</a> .
3	RX overrun	Write to <a href="#">RHR_REG</a> when RX FIFO full.	Read <a href="#">RESUME_REG</a> register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. <a href="#">THR_REG</a> empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read <a href="#">RESUME_REG</a> register. OR 2. Read <a href="#">IIR_REG</a> .
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read <a href="#">IIR_REG</a> .

#### 17.4.4.2.6.2 Wake-up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.4.1.4.1, Wake-Up Interrupt](#)).

#### CAUTION

Wake-up interface implementation in this mode is based on the UARTi\_SIDLEACK low-to-high transition instead of the UARTi\_SIDLEACK state.

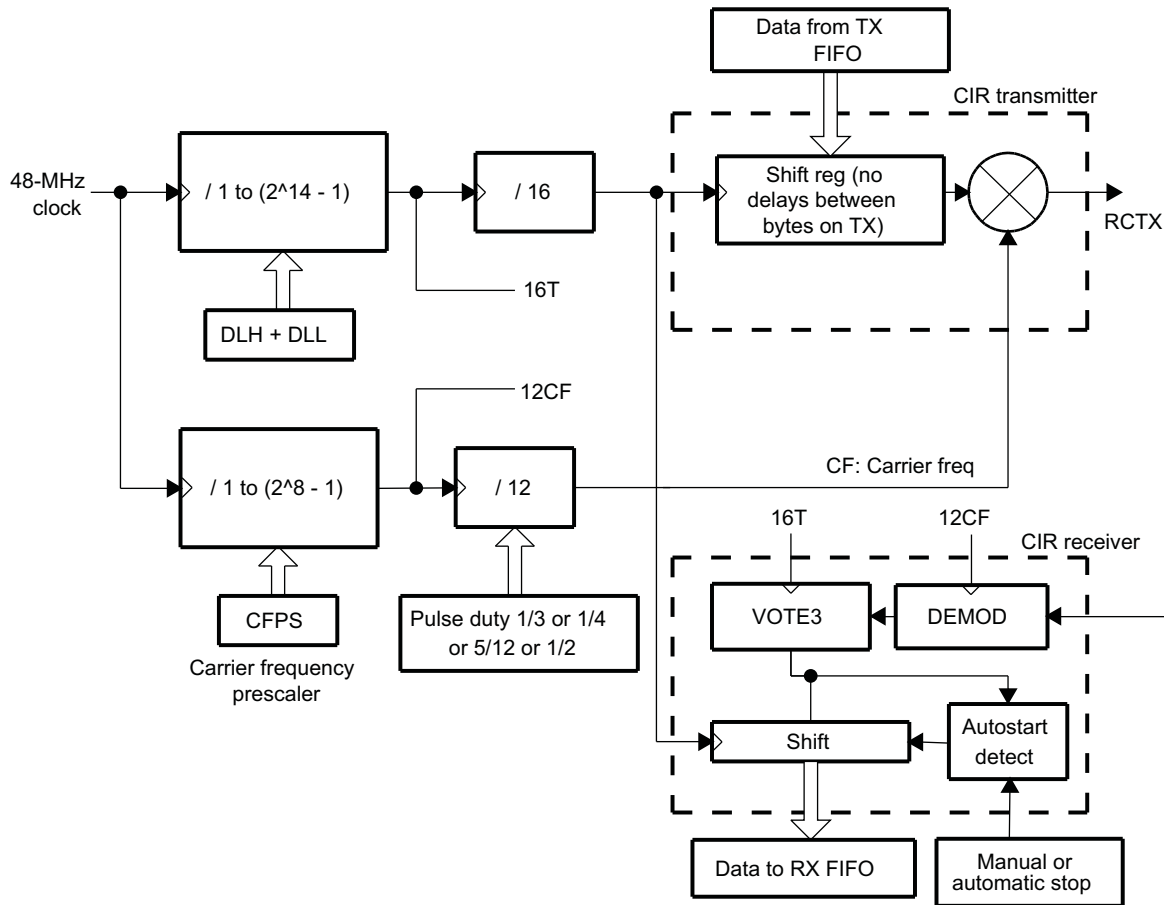

This does not ensure wake-up event generation as expected when configured in smart-idle mode and the system wakes up for a short period.

#### 17.4.4.3 CIR Mode (UART3 Only)

##### 17.4.4.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 17-33](#).

Figure 17-33. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the `UART3.CFPS_REG` register must be set with the correct dividing value to provide the more accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the `CFPS_REG` value must be set to 111 (decimal), which provides a modulation frequency of 36.04 kHz.

**Note:** The `UART3.CFPS_REG` register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the `UART3.MDR2_REG` configuration register. [Table 17-36](#) shows the duty cycle.

**Table 17-36. Duty Cycle**

<b>MDR2_REG[5:4]</b>	<b>Duty Cycle (High Level)</b>
00	1/4
01	1/3
10	5/12
11	1/2

### 17.4.4.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

#### 17.4.4.3.2.1 IRRX Polarity Control

The IRRX polarity control for the CIR mode has the same functionality as that for the IrDA mode (see [Section 17.4.4.2.3.1, IRRX Polarity Control](#)).

#### 17.4.4.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay either between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.MDR1\_REG[5] SCT bit and UART3.ACREG\_REG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART3.IIR\_REG[5] TX\_STATUS\_IT interrupt to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

#### 17.4.4.3.2.3 CIR Reception

There are two methods of stopping reception:

- The MPU can disable the reception by setting the UART3.ACREG\_REG[5] DIS\_IR\_RX bit to 1 when it detects that the reception is complete because of the large number of 0s received. To receive a new frame, the DIS\_IR\_RX bit must be set to 0.
- The reception stops automatically, depending on the value set in the BOF-length register (the UART3.EBLR\_REG[7:0] EBLR field). If the value set in the UART3.EBLR\_REG[7:0] EBLR field is different from 0, this feature is enabled and counts the number of bits received at 0.

When the counter achieves the value defined in the [EBLR\\_REG](#) register, the reception automatically stops and the UART3.IIR\_REG[2] RX\_STOP\_IT bit is set. When 1 is detected on the `uart3.rx_irrx` pin, the reception is automatically enabled.

**CAUTION**

If the UART3.IER\_REG[2] RX\_STOP\_IT interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

### 17.4.4.3.3 CIR Mode Interrupt Management

### 17.4.4.3.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER\_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR\_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER\_REG and UART3.IIR\_REG mappings, depending on the selected mode.

Table 17-37 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.IIR\_REG[5] bit is to indicate that the last bit of infrared data was passed to the uart3\_cts\_rctx pin.

**Table 17-37. CIR Mode Interrupts**

IIR_REG Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR_REG.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

### 17.4.4.3.3.2 Wake-up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see Section 17.4.4.1.4.1, *Wake-Up Interrupt*).

## 17.4.5 Power Management

### 17.4.5.1 UART Mode Power Management

#### 17.4.5.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.IER\_REG[4] SLEEP\_MODE bit to 1 (when the UARTi.EFR\_REG[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti\_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti\_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.SCR\_REG[4] RX\_CTS\_WU\_EN bit to 1. See [Section 17.4.4.1.4.1, Wake-Up Interrupt](#), to understand how to manage the interrupt.

---

**Note:** There must be no writing to the divisor latches, UARTi.DLL\_REG and UARTi.DLH\_REG, to set the baud clock, BCLK, while in sleep mode. It is advisable to disable sleep mode using the UARTi.IER\_REG[4] SLEEP\_MODE bit before writing to the UARTi.DLL\_REG register or the UARTi.DLH\_REG register.

---

#### 17.4.5.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. At the system level, power-reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol. This protocol is used at the system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.SYSC\_REG[2] ENAWAKEUP bit and the UARTi.WER\_REG register).

For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

#### 17.4.5.2 IrDA Mode Power Management (UART3 Only)

##### 17.4.5.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR\_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx\_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3\_rx\_irrx line or when data is written to the TX FIFO.

##### 17.4.5.2.2 System Power Saving

System power saving for the IrDA mode has the same functionality as that for the UART mode (see [Section 17.4.5.1.2, System Power Saving](#)).

#### 17.4.5.3 CIR Mode Power Management (UART3 Only)

##### 17.4.5.3.1 Module Power Saving

Module power saving for the CIR mode has the same functionality as that for the IrDA mode (see [Section 17.4.5.2.1, Module Power Saving](#)).

##### 17.4.5.3.2 System Power Saving

System power saving for the CIR mode has the same functionality as that for the UART mode (see [Section 17.4.5.2.2, System Power Saving](#)).

## 17.5 UART/IrDA/CIR Basic Programming Model

### 17.5.1 UART Programming Model

#### 17.5.1.1 Quick start

This section outlines the procedure for operating the UART module with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART module. It does not cover every UART module feature.

The first programming model covers software reset of the module. The second programming model deals with FIFO and DMA configuration. The last programming model deals with protocol, baud rate and interrupt configuration.

---

**Note:** Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information see [Section 17.4.3.1, Register Access Modes](#).

---

##### 17.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
  - Set the UARTi.SYSC\_REG[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
  - Poll the UARTi.SYSS\_REG[0] RESETDONE bit until it equals 1.

##### 17.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.EFR\_REG register:
  - a. Save the current UARTi.LCR\_REG value.
  - b. Set UARTi.LCR\_REG to 0x00BF.
2. Enable register submode TCR\_TLR to access UARTi.TLR\_REG (part 1 of 2):
  - a. Save the UARTi.EFR\_REG[4] ENHANCED\_EN value.
  - b. Set the UARTi.EFR\_REG[4] ENHANCED\_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.MCR\_REG register:
  - Set UARTi.LCR\_REG to 0x0080.
4. Enable register submode TCR\_TLR to access UARTi.TLR\_REG (part 2 of 2):
  - a. Save the UARTi.MCR\_REG[6] TCR\_TLR value.
  - b. Set the UARTi.MCR\_REG[6] TCR\_TLR bit to 1.
5. Enable FIFO, load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
  - Set the following bits to the desired values:
    - UARTi.FCR\_REG[7:6] RX\_FIFO\_TRIG
    - UARTi.FCR\_REG[5:4] TX\_FIFO\_TRIG
    - UARTi.FCR\_REG[3] DMA\_MODE
    - UARTi.FCR\_REG[0] FIFO\_ENABLE (0: Disable the FIFO/1: Enable the FIFO)

**Note:** The UARTi.FCR\_REG register is not readable.

6. Switch to register configuration mode B to access the UARTi.EFR\_REG register:  
Set UARTi.LCR\_REG to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):  
Set the following bits to the desired values:
  - UARTi.TLR\_REG[7:4] RX\_FIFO\_TRIG\_DMA
  - UARTi.TLR\_REG[3:0] TX\_FIFO\_TRIG\_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):  
Set the following bits to the desired values:
  - UARTi.SCR\_REG[7] RX\_TRIG\_GRANU1
  - UARTi.SCR\_REG[6] TX\_TRIG\_GRANU1
  - UARTi.SCR\_REG[2:1] DMA\_MODE\_2
  - UARTi.SCR\_REG[0] DMA\_MODE\_CTL
9. Restore the UARTi.EFR\_REG[4] ENHANCED\_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.MCR\_REG register:  
Set UARTi.LCR\_REG to 0x0080.
11. Restore the UARTi.MCR\_REG[6] TCR\_TLR value saved in Step 4a.
12. Restore the UARTi.LCR\_REG value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 17.4.2.1.1, Transmit FIFO Trigger](#), to choose the following values:

- UARTi.FCR\_REG[5:4] TX\_FIFO\_TRIG
- UARTi.TLR\_REG[3:0] TX\_FIFO\_TRIG\_DMA
- UARTi.SCR\_REG[6] TX\_TRIG\_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 17.4.2.1.2, Receive FIFO Trigger](#), to choose the following values:

- UARTi.FCR\_REG[7:6] RX\_FIFO\_TRIG
- UARTi.TLR\_REG[7:4] RX\_FIFO\_TRIG\_DMA
- UARTi.SCR\_REG[7] RX\_TRIG\_GRANU1

DMA mode enables the different DMA requests. See [Section 17.4.2.4, FIFO DMA Mode Operation](#), to choose the following values:

- UARTi.FCR\_REG[3] DMA\_MODE
- UARTi.SCR\_REG[2:1] DMA\_MODE\_2
- UARTi.SCR\_REG[0] DMA\_MODE\_CTL

### 17.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate and interrupt settings, perform the following steps:

1. Disable UART to access UARTi.DLL\_REG and UARTi.DLH\_REG:  
Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to 0x7.
2. Switch to register configuration mode B to access the UARTi.EFR\_REG register:  
Set UARTi.LCR\_REG to 0x00BF.
3. Enable access to UARTi.IER\_REG[7:4]:
  - a. Save the UARTi.EFR\_REG[4] ENHANCED\_EN value.
  - b. Set the UARTi.EFR\_REG[4] ENHANCED\_EN bit to 1.
4. Switch to register operational mode to access the UARTi.IER\_REG register:  
Set UARTi.LCR\_REG to 0x0000.
5. Clear the UARTi.IER\_REG (UARTi.IER\_REG[4] SLEEP\_MODE bit to 0 to change UARTi.DLL\_REG and UARTi.DLH\_REG). Set UARTi.IER\_REG to 0x0000.

6. Switch to register configuration mode B to access the UARTi.DLL\_REG and UARTi.DLH\_REG registers:  
Set UARTi.LCR\_REG to 0x00BF.
7. Load the new divisor value:  
Set the UARTi.DLL\_REG[7:0] CLOCK\_LSB and UARTi.DLH\_REG[5:0] CLOCK\_MSB fields to the desired value.
8. Switch to register operational mode to access the UARTi.IER\_REG register:  
Set UARTi.LCR\_REG to 0x0000.
9. Load the new interrupt configuration.(0: Disable the interrupt/1: Enable the interrupt):  
Set the following bits to the desired values:
  - UARTi.IER\_REG[7] CTS\_IT
  - UARTi.IER\_REG[6] RTS\_IT
  - UARTi.IER\_REG[5] XOFF\_IT
  - UARTi.IER\_REG[4] SLEEP\_MODE
  - UARTi.IER\_REG[3] MODEM\_STS\_IT
  - UARTi.IER\_REG[2] LINE\_STS\_IT
  - UARTi.IER\_REG[1] THR\_IT
  - UARTi.IER\_REG[0] RHR\_IT
10. Switch to register configuration mode B to access the UARTi.EFR\_REG register:  
Set UARTi.LCR\_REG to 0x00BF.
11. Restore the UARTi.EFR\_REG[4] ENHANCED\_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop bit, char length) and switch to register operational mode:  
Set UARTi.LCR\_REG[7] DIV\_EN to 0.  
Set UARTi.LCR\_REG[6] BREAK\_EN to 0.  
Set the following bits to the desired values:
  - UARTi.LCR\_REG[5] PARITY\_TYPE\_2
  - UARTi.LCR\_REG[4] PARITY\_TYPE\_1
  - UARTi.LCR\_REG[3] PARITY\_EN
  - UARTi.LCR\_REG[2] NB\_STOP
  - UARTi.LCR\_REG[1:0] CHAR\_LENGTH
13. Load the new UART mode:  
Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to the desired value.  
See [Section 17.4.4.1.2, Choosing the Appropriate Divisor Value](#), to choose the following values:
  - UARTi.DLL\_REG[7:0] CLOCK\_LSB
  - UARTi.DLH\_REG[5:0] CLOCK\_MSB
  - UARTi.MDR1\_REG[2:0] MODE\_SELECT
 See [Section 17.4.4.1.3.1, Frame Formatting](#), to choose the following values:
  - UARTi.LCR\_REG[5] PARITY\_TYPE\_2
  - UARTi.LCR\_REG[4] PARITY\_TYPE\_1
  - UARTi.LCR\_REG[3] PARITY\_EN
  - UARTi.LCR\_REG[2] NB\_STOP
  - UARTi.LCR\_REG[1:0] CHAR\_LENGTH

### 17.5.1.2 Hardware and Software Flow Control Configuration

This section outlines the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

---

**Note:** Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 17.4.3.1, Register Access Modes](#).

---

#### 17.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following procedure:

1. Switch to register configuration mode A to access the UARTi.MCR\_REG register:
  - a. Save the current UARTi.LCR\_REG.
  - b. Set UARTi.LCR\_REG to 0x0080.
2. Enable register submode TCR\_TLR to access UARTi.TCR\_REG (part 1 of 2):
  - a. Save the UARTi.MCR\_REG[6] TCR\_TLR value.
  - b. Set UARTi.MCR\_REG[6] TCR\_TLR = 1.
3. Switch to register configuration mode B to access the UARTi.EFR\_REG register:  
Set UARTi.LCR\_REG to 0x00BF.
4. Enable register submode TCR\_TLR to access the UARTi.TCR\_REG register (part 2 of 2):
  - a. Save the UARTi.EFR\_REG[4] ENHANCED\_EN value.
  - b. Set the UARTi.EFR\_REG[4] ENHANCED\_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:  
Set the following bits to the desired values:
  - UARTi.TCR\_REG[7:4] AUTO\_RTS\_START
  - UARTi.TCR\_REG[3:0] AUTO\_RTS\_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.EFR\_REG[4] ENHANCED\_EN value saved in Step 4a.  
Set the following bits to the desired values:
  - UARTi.EFR\_REG[7] AUTO\_CTS\_EN (0: Disable/1: Enable)
  - UARTi.EFR\_REG[6] AUTO\_RTS\_EN (0: Disable/1: Enable)
 Restore UARTi.EFR\_REG[4] ENHANCED\_EN to the saved value.
7. Switch to register configuration mode A to access UARTi.MCR\_REG:  
Set UARTi.LCR\_REG to 0x0080.
8. Restore the UARTi.MCR\_REG[6] TCR\_TLR value saved in Step 2a.
9. Restore the UARTi.LCR\_REG value saved in Step 1a.

See [Section 17.4.4.1.3.2, Hardware Flow Control](#), to choose the following values:

- UARTi.EFR\_REG[7] AUTO\_CTS\_EN
- UARTi.EFR\_REG[6] AUTO\_RTS\_EN
- UARTi.TCR\_REG[7:4] AUTO\_RTS\_START
- UARTi.TCR\_REG[3:0] AUTO\_RTS\_HALT

#### 17.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following procedure:

1. Switch to register configuration mode B to access the UARTi.EFR\_REG register.
  - a. Save the current UARTi.LCR\_REG.
  - b. Set UARTi.LCR\_REG to 0x00BF.
2. Enable register submode XOFF to access the UARTi.XOFF1\_REG and UARTi.XOFF2\_REG registers:
  - a. Save the UARTi.EFR\_REG[4] ENHANCED\_EN value.
  - b. Set the UARTi.EFR\_REG[4] ENHANCED\_EN bit to 0.

3. Load the new software flow control characters:  
Set the following bits to the desired values:
    - UARTi.XON1\_ADDR1\_REG[7:0] XON\_WORD1
    - UARTi.XON2\_ADDR2\_REG[7:0] XON\_WORD2
    - UARTi.XOFF1\_REG[7:0] XOFF\_WORD1
    - UARTi.XOFF2\_REG[7:0] XOFF\_WORD2
  4. Enable access to UARTi.MCR\_REG[7:5] and enable register submode TCR\_TLR to access UARTi.TCR\_REG (part 1 of 2):  
Set the UARTi.EFR\_REG[4] ENHANCED\_EN bit to 1.
  5. Switch to register configuration mode A to access the UARTi.MCR\_REG register:  
Set UARTi.LCR\_REG to 0x0080.
  6. Enable register submode TCR\_TLR to access UARTi.TCR\_REG (part 2 of 2) and enable or disable XON any function:
    - a. Save the UARTi.MCR\_REG[6] TCR\_TLR value.
    - b. Set the UARTi.MCR\_REG[6] TCR\_TLR to 1.  
Set UARTi.MCR\_REG[5] XON\_EN to the desired value (0: Disable/1: Enable).
  7. Switch to register configuration mode B to access the UARTi.EFR\_REG register:  
Set UARTi.LCR\_REG to 0x00BF.
  8. Load the new start and halt trigger values for software flow control:  
Set the following bits to the desired values:
    - UARTi.TCR\_REG[7:4] AUTO\_RTS\_START
    - UARTi.TCR\_REG[3:0] AUTO\_RTS\_HALT
  9. Enable or disable special char function and load the new software flow control mode and restore the UARTi.EFR\_REG[4] ENHANCED\_EN value saved in Step 2a:  
Set the following bits to the desired values:
    - UARTi.EFR\_REG[5] SPEC\_CHAR (0: Disable/1: Enable)
    - UARTi.EFR\_REG[3:0] SW\_FLOW\_CONTROL
 Restore UARTi.EFR\_REG[4] ENHANCED\_EN to the saved value.
  10. Switch to register configuration mode A to access the UARTi.MCR\_REG register:  
Set UARTi.LCR\_REG to 0x0080.
  11. Restore the UARTi.MCR\_REG[6] TCR\_TLR value saved in Step 6a.
  12. Restore the UARTi.LCR\_REG value saved in Step 1a.
- See [Section 17.4.4.1.3.3](#), *Software Flow Control*, to choose the following values:
- UARTi.EFR\_REG[5] SPEC\_CHAR
  - UARTi.EFR\_REG[3:0] SW\_FLOW\_CONTROL
  - UARTi.TCR\_REG[7:4] AUTO\_RTS\_START
  - UARTi.TCR\_REG[3:0] AUTO\_RTS\_HALT
  - UARTi.XON1\_ADDR1\_REG[7:0] XON\_WORD1
  - UARTi.XON2\_ADDR2\_REG[7:0] XON\_WORD2
  - UARTi.XOFF1\_REG[7:0] XOFF\_WORD1
  - UARTi.XOFF2\_REG[7:0] XOFF\_WORD2

## 17.5.2 IrDA Programming Model (UART3 Only)

### 17.5.2.1 SIR Mode

### 17.5.2.1.1 Receive

The following programming model explains how to program the module to receive IrDA frame with parity forced to 1, baud rate = 112.5 Kbs, FIFOs disable, 2 stop bits, 8-bit word length.

1. **Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG:**  
Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to 0x7.
2. **Grant access to DLL\_REG and DLH\_REG (LCR\_REG[7] DIV\_EN = 0x1)**  
UART3.LCR\_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR\_REG register in IrDA mode.)
3. **Load the new baud rate (115.2Kbs)**  
UART3.DLL\_REG = 0x1A  
UART3.DLH\_REG = 0x00
4. **Set SIR Mode**  
UART3.MDR1\_REG[2:0] MODE\_SELECT = 0x1
5. **Disable access to DLL\_REG and DLH\_REG and switch to register operational mode**  
UART3.LCR\_REG = 0x00.
6. **Optional: Enable RHR interrupt**  
UART3.IER\_REG[0] RHR\_IT = 0x1

### 17.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit IrDA 6 bytes frame with no parity, baud rate = 112.5Kbs, FIFOs disable, 3/16 encoding, 2 stop bits, 7 bits word length

1. **Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG:**  
Set MDR1\_REG[2:0] MODE\_SELECT = 0x7).
2. **Grant access to EFR\_REG**  
UART3.LCR\_REG = 0xBF
3. **Enable the enhanced features (EFR\_REG[4] ENAHNCED\_EN = 0x1)**  
UART3.EFR\_REG = 0x10.
4. **Grant access to DLL\_REG and DLH\_REG (LCR\_REG[7] DIV\_EN = 0x1)**  
UART3.LCR\_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR\_REG register in IrDA mode).
5. **Load the new baud rate (115.2Kbs)**  
UART3.DLL\_REG = 0x1A  
UART3.DLH\_REG = 0x00
6. **Set SIR Mode (MDR1\_REG[2:0] MODE\_SELECT = 0x1)**  
UART3.MDR1\_REG = 0x01.
7. **Disable access to DLL\_REG and DLH\_REG and switch to register operational mode**  
**UART3.LCR\_REG**  
UART3.LCR\_REG = 0x00.
8. **Force DTR output to active**  
UART3.MCR\_REG[0] DTR = 0x1
9. **Optional: Enable THR interrupt**  
UART3.IER\_REG[1] THR\_IT = 0x1
10. **Set transmit frame length to 6 bytes**  
UART3.TXFLL\_REG = 0x06
11. **Set 7 starts of frame transmission**  
UART3.EBLR\_REG = 0x08
12. **Optional: Set SIR pulse width to be 1.6 μs**  
UART3.ACREG\_REG[7] PULSE\_TYPE = 0x1
13. **Load THR\_REG with the desired data to be transmitted**

## 17.5.2.2 MIR Mode

### 17.5.2.2.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 1.152Mbps, FIFOs disable

1. **Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG**  
Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to 0x7.
2. **Grant access to DLL\_REG and DLH\_REG (LCR\_REG[7] DIV\_EN = 0x1)**  
UART3.LCR\_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR\_REG register in IrDA mode).
3. **Load the new baud rate (1.152 Mbs)**  
UART3.DLL\_REG = 0x01  
UART3.DLH\_REG = 0x00.
4. **Set MIR Mode**  
UART3.MDR1\_REG[2:0] MODE\_SELECT = 0x4
5. **Disable access to DLL\_REG and DLH\_REG and switch to register operational mode**  
UART3.LCR\_REG = 0x00.
6. **Force DTR output to active (MCR\_REG[0] DTR = 0x1)**  
**Force RTS output to active (MCR\_REG[1] RTS = 0x1)**  
UART3.MCR\_REG = 0x3
7. **Optional: Enable RHR interrupt**  
UART3.IER\_REG[0] RHR\_IT = 0x1

### 17.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit IrDA 60 bytes frame with no parity, baud rate = 1.152Mbps, FIFOs disable

1. **Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG:**  
Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to 0x7.
2. **Grant access to DLL\_REG and DLH\_REG (LCR\_REG[7] DIV\_EN = 0x1)**  
UART3.LCR\_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR\_REG register in IrDA mode.)
3. **Load the new baud rate (1.152 Mbs)**  
UART3.DLL\_REG = 0x01  
UART3.DLH\_REG = 0x00
4. **Set MIR Mode**  
UART3.MDR1\_REG[2:0] MODE\_SELECT = 0x4.
5. **Disable access to DLL\_REG and DLH\_REG and switch to register operational mode:**  
UART3.LCR\_REG = 0x00.
6. **Force DTR output to active**  
UART3.MCR\_REG[0] DTR = 0x1
7. **Optional: Enable THR interrupt**  
UART3.IER\_REG[1] THR\_IT = 0x1
8. **Set frame length to 60 bytes**  
UART3.TXFLL\_REG = 0x3C
9. **Optional: Transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)**  
UART3.EBLR\_REG = 0x08
10. **SIP will be send at the end of transmission**  
UART3.ACREG\_REG[3] = 0x1
11. **Load THR\_REG with the desired data to be transmitted**

### 17.5.2.2.3 FIR Mode

#### 17.5.2.2.3.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG: Set UARTi.MDR1\_REG[2:0] MODE\_SELECT to 0x7.
2. Grant access to DLL\_REG and DLH\_REG (LCR\_REG[7] DIV\_EN = 0x1 UART3.LCR\_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR\_REG register in IrDA mode.)
3. FIFO clear and enable FCR\_REG = 0x7 (Tx/Rx FIFO trigger : FCR\_REG[7:6] & FCR\_REG[5:4]) LCR\_REG[7]=0.
4. Set FIR Mode UART3.MDR1\_REG[2:0] MODE\_SELECT = 0x5.
5. Set frame length RXFLL\_REG = 0xA (Data + CRC + STO).
6. Disable access to DLL\_REG and DLH\_REG and switch to register operational mode UART3.LCR\_REG[7] DIV\_EN = 0x0.
7. Optional: Enable RHR interrupt UART3.IER\_REG[0] RHR\_IT = 0x1.

#### 17.5.2.2.3.2 Transmit

The following programming model explains how to program the module to transmit IrDA 4 bytes frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. Disable UART before accessing UARTi.DLL\_REG and UARTi.DLH\_REG: Set MDR1\_REG[2:0] MODE\_SELECT = 0x7).
2. Grant access to EFR\_REG UART3.LCR\_REG = 0xBF.
3. Enable the enhanced features (EFR\_REG[4] ENAHNCED\_EN = 0x1) UART3.EFR\_REG = 0x10.
4. FIFO clear and enable FCR\_REG = 0x7 (Tx/Rx FIFO trigger: FCR\_REG[7:6] and FCR\_REG[5:4]) LCR\_REG[7] = 0
5. Set FIR mode and enable auto-SIP mode MDR1\_REG = 0x45.
6. Set Frame Length TXFLL\_REG = 0x4 TXFLH\_REG = 0x0 RXFLL\_REG = 0xA (Data + CRC + STO) RXFLH\_REG = 0x0.
7. Force DTR output to active UART3.MCR\_REG[0] DTR = 0x1.
8. Optional: Enable THR interrupt UART3.IER\_REG[1] THR\_IT = 0x1.
9. Load THR\_REG with the desired data to be transmitted.

## 17.6 UART/IrDA/CIR Register Manual

### 17.6.1 UART/IrDA/CIR Instance Summary

Table 17-38 shows the base address and address space for the UART/IrDA/CIR module instances.

**Table 17-38. UART/IrDA/CIR Instance Summary**

Module Name	Base Address	Size
UART1 <sup>(1)</sup>	0x4806 A000	1K byte
UART2 <sup>(1)</sup>	0x4806 C000	1K byte
UART3 <sup>(2)</sup>	0x4902 0000	1K byte

(1) UART only

(2) UART, IrDA and CIR

### 17.6.2 UART/IrDA/CIR Register Summary

**Note:** UART/IrDA/CIR registers access depends on access mode and submode. For more information, see [Section 17.4.3.1, Register Access Modes](#).

**Table 17-39. UART/IrDA/CIR Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	UART1 Physical Address	UART2 Physical Address	UART3 Physical Address
<a href="#">DLL_REG</a>	RW	8	0x000	0x4806 A000	0x4806 C000	0x4902 0000

### 17.6.3 UART/IrDA/CIR Register Description

**Table 17-40. DLL\_REG**

<b>Address Offset</b>	0x000															
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>															
<b>Description</b>	Divisor latches low  This register, with <a href="#">DLH_REG</a> , stores the 14-bit divisor for generation of the baud clock in the baud rate generator. <a href="#">DLH_REG</a> stores the most-significant part of the divisor. <a href="#">DLL_REG</a> stores the least-significant part of the divisor.  <b>Note:</b> <a href="#">DLL_REG</a> and <a href="#">DLH_REG</a> can be written to only before sleep mode is enabled (before <a href="#">IER_REG</a> [4] is set).															
<b>Type</b>	RW															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Reserved								CLOCK_LSB							
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>											<b>Type</b>	<b>Reset</b>	
15:8	Reserved		Read returns 0x00.											R	0x00	
7:0	CLOCK_LSB		Stores the 8-bit LSB divisor value											RW	0x00

**Table 17-42. RHR\_REG**

<b>Address Offset</b>	0x000															
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>															
<b>Description</b>	Receive holding register  The receiver section consists of the receiver holding register ( <a href="#">RHR_REG</a> ) and the receiver shift register. The <a href="#">RHR_REG</a> is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the <a href="#">RHR_REG</a> . If the FIFO is disabled, location zero of the FIFO is used to store the single data character.  Note: If an overflow occurs the data in the <a href="#">RHR_REG</a> is not overwritten.															
<b>Type</b>	R															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 17-44. THR\_REG**

<b>Address Offset</b>	0x000															
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>															
<b>Description</b>	Transmit holding register															
	The transmitter section consists of the transmit holding register ( <a href="#">THR_REG</a> ) and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the <a href="#">THR_REG</a> . The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.															
<b>Type</b>	W															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 17-54. EFR\_REG

<b>Address Offset</b>	0x008
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Enhanced feature register This register enables or disables enhanced features. Most enhanced functions apply only to UART modes, but <a href="#">EFR_REG[4]</a> enables write accesses to <a href="#">FCR_REG[5:4]</a> , the TX trigger level, which is also used in IrDA modes.
<b>Type</b>	RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								AUTO_CTS_EN	AUTO_RTS_EN	SPEC_CHAR	ENHANCED_LEN	SW_FLOW_CONTROL			

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	AUTO_CTS_EN	Auto-CTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-CTS flow control is enabled; transmission is halted when the nCTS pin is high (inactive).	RW	0
6	AUTO_RTS_EN	Auto-RTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-RTS flow control is enabled; nRTS pin goes high (inactive) when the receiver FIFO HALT trigger level, <a href="#">TCR_REG[3:0]</a> , is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.	RW	0
5	SPEC_CHAR	(UART mode only) Special character detect 0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and <a href="#">IIR_REG</a> bit 4 is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to <a href="#">IER_REG</a> bits [7:4], <a href="#">FCR_REG</a> bits [5:4], and <a href="#">MCR_REG</a> bits [7:5] 0x1: Enables writing to <a href="#">IER_REG</a> bits [7:4], <a href="#">FCR_REG</a> bits [5:4], and <a href="#">MCR_REG</a> bits [7:5]	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit [3:0]. See <a href="#">Table 17-32</a> . In IrDA mode, bits [1:0] select IR address to check. See <a href="#">Section 17.2.5.2.1.7</a> , <i>IR Address Checking</i> .	RW	0x0

**Table 17-56. LCR\_REG**

<b>Address Offset</b>	0x00C
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Line control register  LCR_REG[6:0] define parameters of the transmission and reception for UART mode. LCR_REG[7] is used to put the module in operational mode or Configuration_Mode_A/B.
<b>Type</b>	RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DIV_EN	BREAK_EN	PARITY_TYPE2	PARITY_TYPE1	PARITY_EN	NB_STOP	CHAR_LENGTH	

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00	R	0x00
7	DIV_EN	0x0: Operational mode 0x1: Divisor latch enable; put the module in Configuration_Mode_A/B. Allows access to <a href="#">DLL_REG</a> , <a href="#">DLH_REG</a> , and other registers (see <a href="#">Section 17.6.2, UART/IrDA/CIR Register Mapping Summary</a> ). Configuration_Mode_B: LCR_REG[7:0] = 0xBF Else, Configuration_Mode_A	RW	0
6	BREAK_EN	Break control bit. UART mode only. <b>Note:</b> When LCR_REG[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR_REG[6] = 1. 0x0: Normal operating condition 0x1: Forces the transmitter output to go low to alert the communication terminal. TX line is forced to 0 and remains in this state while BREAK_EN = 1.	RW	0
5	PARITY_TYPE2	Selects the forced parity format (if LCR_REG[3] = 1). UART mode only. If LCR_REG[5] = 1 and LCR_REG[4] = 0, the parity bit is forced to 1 in the transmitted and received data. If LCR_REG[5] = 1 and LCR_REG[4] = 1, the parity bit is forced to 0 in the transmitted and received data.	RW	0
4	PARITY_TYPE1	UART mode only 0x0: Odd parity is generated (if LCR_REG[3] = 1). 0x1: Even parity is generated (if LCR_REG[3] = 1).	RW	0
3	PARITY_EN	UART mode only 0x0: No parity 0x1: A parity bit is generated during transmission, and the receiver checks for received parity.	RW	0
2	NB_STOP	Specifies the number of stop bits. UART mode only. 0x0: 1 stop bit (word length = 5, 6, 7, 8) 0x1: 1.5 stop bits (word length = 5) 1 - 2 stop bits (word length = 6, 7, 8)	RW	0
1:0	CHAR_LENGTH	Specifies the word length to be transmitted or received. UART mode only. 0x0: 5 bits 0x1: 6 bits 0x2: 7 bits 0x3: 8 bits	RW	0x0

**Table 17-62. LSR\_REG**

<b>Address Offset</b>	0x014
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Line status register
<b>Type</b>	R

**UART Bitfield Details**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RX_FIFO_STS	TX_SR_E	TX_FIFO_E	RX_BI	RX_FE	RX_PE	RX_OE	RX_FIFO_E

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	RX_FIFO_STS	0x0: Normal operation 0x1: At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO.	R	0
6	TX_SR_E	0x0: Transmitter hold (TX FIFO) and shift registers are not empty. 0x1: Transmitter hold (TX FIFO) and shift registers are empty	R	1
5	TX_FIFO_E	0x0: Transmit hold register (TX FIFO) is not empty. 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.	R	1
4	RX_BI	0x0: No break condition 0x1: A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame).	R	0
3	RX_FE	0x0: No framing error in data being read from RX FIFO 0x1: Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit).	R	0
2	RX_PE	0x0: No parity error in data being read from RX FIFO 0x1: Parity error in data being read from RX FIFO	R	0
1	RX_OE	0x0: No overrun error 0x1: Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full.	R	0
0	RX_FIFO_E		R	0

Bits	Field Name	Description	Type	Reset
0x0:		No data in the receive FIFO		
0x1:		At least one data character in the RX FIFO

**CIR Bitfield Details**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								THR_EMPTY	Reserved	Reserved	Reserved				Reserved

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	THR_EMPTY	0x0: Transmit holding register (TX FIFO) is not empty. 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.	R	0
6	Reserved			
5	Reserved	Reserved	R	1
4:1	Reserved			
0	Reserved	Reserved	R	1

**IrDA Bitfield Details**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								THR_EMPTY	STS_FIFO_FUL	RX_LAST_BYTE	FRAME_TOO_LONG	ABORT	CRC	STS_FIFO_E	RX_FIFO_E

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	THR_EMPTY	0x0: Transmit holding register (TX FIFO) is not empty. 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.	R	0
6	STS_FIFO_FUL		R	1

Bits	Field Name	Description	Type	Reset
		0x0: Status FIFO not full 0x1: Status FIFO full		
5	RX_LAST_BYTE	Receive last byte  0x0: The RX FIFO ( <a href="#">RHR_REG</a> ) does not contain the last byte of the frame to be read. 0x1: The RX FIFO ( <a href="#">RHR_REG</a> ) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the <a href="#">LSR_REG</a> register.	R	1
4	FRAME_TOO_LONG	Frame too long  0x0: No frame-too-long error in frame 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by <a href="#">RXFLH_REG</a> and <a href="#">RXFLL_REG</a> registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.	R	0
3	ABORT	 0x0: No abort pattern error in frame 0x1: Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol.	R	0
2	CRC	 0x0: No CRC error in frame 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read)	R	0
1	STS_FIFO_E	 0x0: Status FIFO not empty 0x1: Status FIFO empty	R	0
0	RX_FIFO_E	 0x0: At least one data character in the RX FIFO 0x1: No data in the receive FIFO	R	1

<b>Address Offset</b>	0x018
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Modem status register. UART mode only.  This register provides information about the current state of the control lines from the modem, data set, or peripheral device to the MPU. It also indicates when a control input from the modem changes state.
<b>Type</b>	R

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								NCD_STS	NRI_STS	NDSR_STS	NCTS_STS	DCD_STS	RI_STS	DSR_STS	CTS_STS

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	NCD_STS	In loopback mode, it is equivalent to <a href="#">MCR_REG[3]</a> .	R	-
6	NRI_STS	This bit is the complement of the nRI input. In loopback mode, it is equivalent to <a href="#">MCR_REG[2]</a> .	R	-
5	NDSR_STS	In loopback mode, it is equivalent to <a href="#">MCR_REG[0]</a> .	R	-
4	NCTS_STS	This bit is the complement of the nCTS input. In loopback mode, it is equivalent to <a href="#">MCR_REG[1]</a> .	R	-
3	DCD_STS	Indicates that <a href="#">MCR_REG[3]</a> in loopback changed. Cleared on a read.	R	0
2	RI_STS	Indicates that nRI input (or <a href="#">MCR_REG[2]</a> in loopback) changed state from low to high. Cleared on a read.	R	0
1	DSR_STS	0x1: Indicates that <a href="#">MCR_REG[0]</a> in loopback changed state. Cleared on a read.	R	0
0	CTS_STS	0x1: Indicates that nCTS input (or <a href="#">MCR_REG[1]</a> in loopback) changed state. Cleared on a read.	R	0

**Table 17-80. MDR2\_REG**

<b>Address Offset</b>	0x024
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Mode definition register 2 IR-IrDA and IR-CIR modes only  MDR2_REG[0] describes the status of the interrupt in IIR_REG[5]. The IRTX_UNDERRUN bit must be read after an IIR_REG[5] TX_STATUS_IT interrupt occurs. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1_REG[2:0].
<b>Type</b>	RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved	IRRXINVERT	CIR_PULSE_MODE	UART_PULSE	STS_FIFO_TRIG	IRTX_UNDERRUN		

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	Reserved		R	0
6	IRRXINVERT	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x00
3	UART_PULSE	UART mode only. Used to allow pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with pulse shaping	RW	0
2:1	STS_FIFO_TRIG	Only for IR-IrDA mode	RW	0x00

Bits	Field Name	Description	Type	Reset
		Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries		
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the <a href="#">IIR_REG[5]</a> interrupt occurs, the meaning of the interrupt is: 0x0: The last bit of the frame was transmitted successfully without error. 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the <a href="#">RESUME_REG</a> register is read.	R	0

**Table 17-102. ACREG\_REG**

<b>Address Offset</b>	0x03C
<b>Physical Address</b>	Please refer to <a href="#">Table 17-39</a>
<b>Description</b>	Auxiliary control register IrDA-CIR mode only
<b>Type</b>	RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	PULSE_TYPE	SIR pulse-width select: 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 $\mu$ s	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 0x1: Disables RX input (permanent state; independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	0x0: Long stop bits cannot be transmitted. TX underrun is enabled. 0x1: Long stop bits can be transmitted. TX underrun is disabled.	RW	0
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP).	RW	0

Bits	Field Name	Description	Type	Reset
		If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.		
2	SCTX_EN	Store and control TX start. When <a href="#">MDR1_REG[5]</a> = 1 and the MPU writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The MPU can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.	RW	0
0	EOT_EN	EOT (end-of-transmission) bit. The MPU writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the MPU writes to the <a href="#">THR_REG</a> (TX FIFO).	RW	0

<b>Description</b>	BOF length register. IR-IrDA mode only In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).															
<b>Type</b>	RW

<b>Description</b>	Wake-up enable register															
	The UART wake-up enable register is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/ or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such.

### 18.1 High-Speed I<sup>2</sup>C Controller Overview

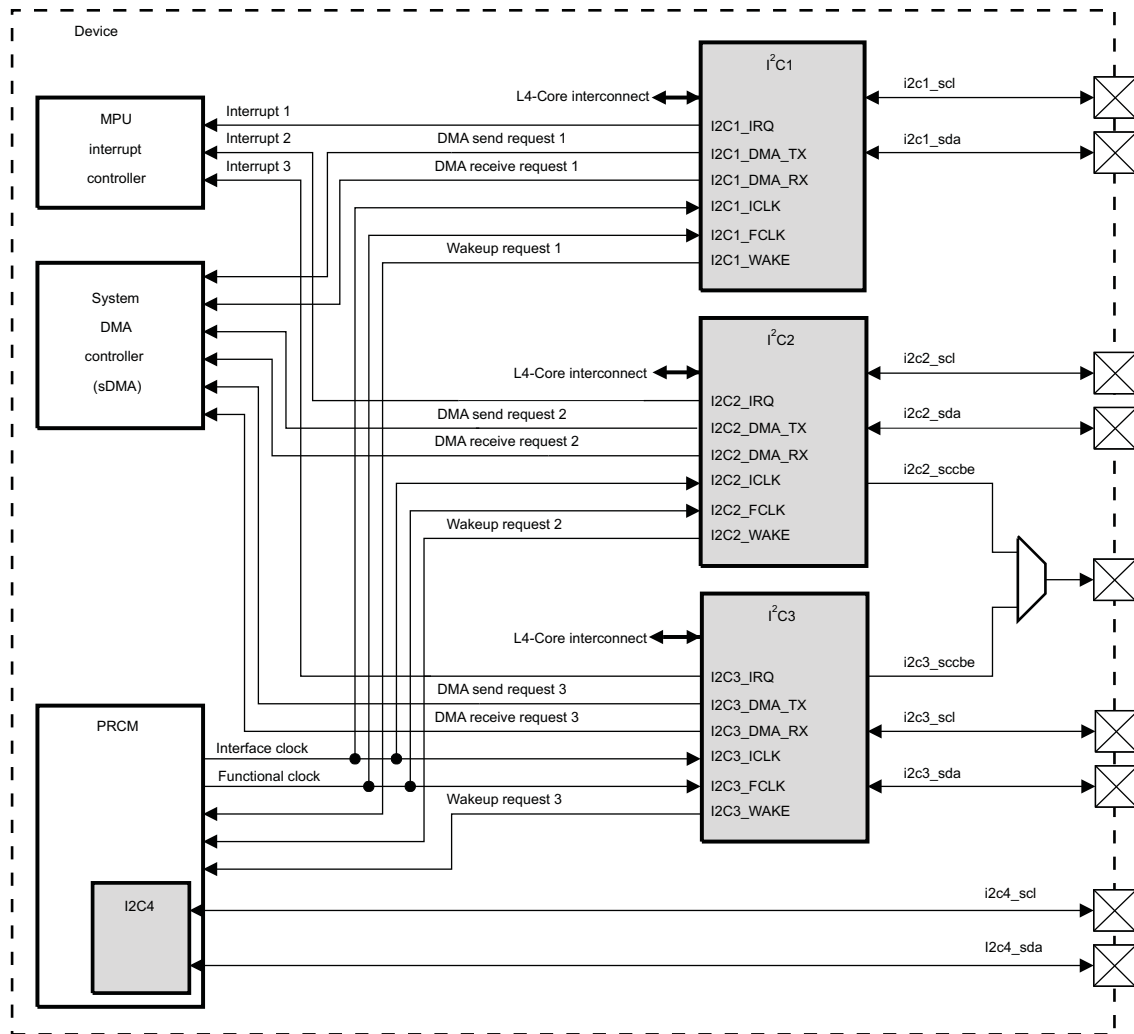

The device contains three multimaster high-speed (HS) inter-integrated circuit (I<sup>2</sup>C) controllers (I<sup>2</sup>C<sub>i</sub> modules, where *i* = 1, 2, 3), each of which provides an interface between a local host (LH), such as the MPU subsystem, and any I<sup>2</sup>C-bus-compatible device that connects through the I<sup>2</sup>C serial bus. External components attached to the I<sup>2</sup>C bus can serially transmit/receive up to 8 bits of data to/from the LH device through the 2-wire I<sup>2</sup>C interface.

Each multimaster HS I<sup>2</sup>C controller can be configured to act like a slave or master I<sup>2</sup>C-compatible device. Moreover, each multimaster HS I<sup>2</sup>C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I<sup>2</sup>C controllers I<sup>2</sup>C<sub>2</sub> and I<sup>2</sup>C<sub>3</sub> can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains an additional master transmitter HS I<sup>2</sup>C interface (I<sup>2</sup>C<sub>4</sub>) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing. Texas Instruments provides a global solution with the device connected to power chips (TWL4030 device).

Figure 18-1 shows the HS I<sup>2</sup>C controllers in the device.

Figure 18-1. HS I<sup>2</sup>C Controllers

I2C-001

The three multimaster HS I<sup>2</sup>C controllers have the following features:

- Compliance with Philips I<sup>2</sup>C specification version 2.1
- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- Support for HS mode for transfer up to 3.4M bits/s
- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 module, up to 100K bits/s
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read or write
  - 8 bytes for I2C1 and I2C2
  - 64 bytes for I2C3
- Module enable/disable capability
- Programmable clock generation
- 8-bit-wide data access
- Low-power consumption design
- Two DMA channels
- Wide interrupt capability

The master transmitter HS I<sup>2</sup>C controller I2C4 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

---

**Note:** The I2C4 clock frequency in HS mode is equal to the SYS\_CLK clock frequency divided by 15.

---

---

**Note:** Before using HS I<sup>2</sup>C mode, determine that the target device supports this mode.

---

## 18.2 High-Speed I<sup>2</sup>C Controller Environment

### 18.2.1 Multimaster HS I<sup>2</sup>C Controllers in I<sup>2</sup>C Mode

Figure 18-2 shows the multimaster HS I<sup>2</sup>C controllers and their related connections with I<sup>2</sup>C-compliant devices in I<sup>2</sup>C mode.

**Figure 18-2. Multimaster HS I<sup>2</sup>C Controllers and Typical Connections to I<sup>2</sup>C Devices**

#### 18.2.1.1 Multimaster HS I<sup>2</sup>C Controller Pins for Typical Connections in I<sup>2</sup>C Mode

Figure 18-3 shows the multimaster HS I<sup>2</sup>C controller pins used for typical connections with I<sup>2</sup>C devices.

**Figure 18-3. Multimaster HS I<sup>2</sup>C Controller Interface Signals in I<sup>2</sup>C Mode**

#### 18.2.1.2 I<sup>2</sup>C Interface Typical Connections

Table 18-1 lists the pins associated with the I<sup>2</sup>C interface.

**Table 18-1. Input/Output**

Signal	I/O <sup>(1)</sup>	Description	Reset Value
i2ci_scl	I/O(OD)	I <sup>2</sup> C serial clock line <sup>(2)</sup> . Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z
i2ci_sda	I/O(OD)	I <sup>2</sup> C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z

<sup>(1)</sup> I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

<sup>(2)</sup> This signal is also used as re-timing input.

#### 18.2.1.3 I<sup>2</sup>C Typical Connection Protocol and Data Format

### 18.2.1.3.1 Serial Data Format

The I<sup>2</sup>C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line (i2ci\_sda) is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I<sup>2</sup>C. Figure 18-4 shows a typical I<sup>2</sup>C communication format.

Figure 18-4. I<sup>2</sup>C Data Transfer

### 18.2.1.3.2 Data Validity

The data on the serial data line must be stable during the high period of the clock i2ci\_scl. The high and low states of the data line can change only when the clock signal on the serial clock line is low.

Figure 18-5 is an example of data validity requirements.

Figure 18-5. Bit Transfer on the I<sup>2</sup>C Bus

### 18.2.1.3.3 Start and Stop Conditions

The I<sup>2</sup>C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the i2ci\_sda line while i2ci\_scl is high.
- A P condition is a low-to-high transition on the i2ci\_sda line while i2ci\_scl is high.

The bus is considered busy after the S condition (the I2Ci.I2C\_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C\_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 18-6 shows the waveforms that occur during an S and a P condition.

**Figure 18-6. S and P Condition Events****18.2.1.3.4 Addressing**

The I<sup>2</sup>C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

**18.2.1.3.4.1 Data Transfer Format in F/S Mode**

Figure 18-7 shows the I<sup>2</sup>C data transfer format in F/S mode.

**Figure 18-7. I<sup>2</sup>C Data Transfer Formats in F/S Mode**

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) addressing format with repeated start condition

I2C-007

The first word after a S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W\_ bit.

The LSB R/W\_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W\_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W\_ bit. If the R/W\_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W\_ bit is 1, the next byte contains data transmitted from the slave to the master.

### 18.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 18-8 shows the I<sup>2</sup>C data transfer format in HS mode.

Figure 18-8. I<sup>2</sup>C Data Transfers in HS Mode

I2C-008

Each multimaster HS I<sup>2</sup>C controller module can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 18-8.

**Note:** For more information, see *I<sup>2</sup>C Bus Specification v2.1*, January 2000.

### 18.2.1.3.5 Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on serial data line `i2ci_sda` in synchronization with the self-generated clock pulses on serial clock line `i2ci_scl`. When the intervention of the processor is required (`I2Ci.I2C_STAT[10]` XUDF bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low.

### 18.2.1.3.6 Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 18-7), if `R/W_` is high, the module enters master receiver mode after the slave address byte and bit `R/W_` are transmitted. Serial data bits received on bus line `i2ci_sda` are shifted in in synchronization with the self-generated clock pulses on `i2ci_scl`. When the intervention of the processor is required (`I2Ci.I2C_STAT[11]` ROVR bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low. At the end of a transfer, a P condition is generated.

### 18.2.1.3.7 Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 18-7), slave transmitter mode is entered if the slave address byte is the same as its own address, and when the `R/W_` bit transmitted by the master transmitter is high. The slave transmitter shifts the serial data out on data line `i2ci_sda` in synchronization with the clock pulses generated by the master device. It does not generate the clock, but it can hold clock line `i2ci_scl` low when intervention of the LH is required (the `I2Ci.I2C_STAT[10]` XUDF bit).

### 18.2.1.3.8 Slave Receiver

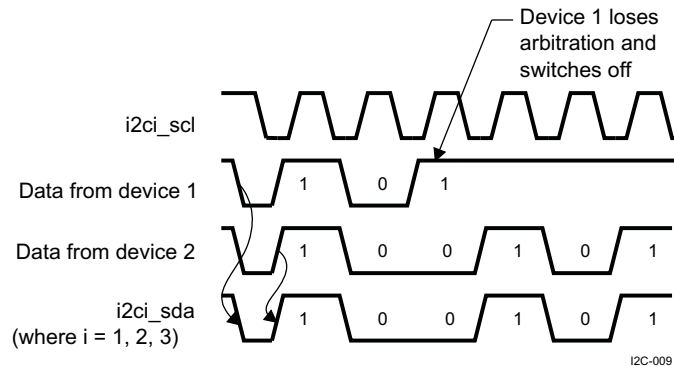

In slave receiver mode, serial data bits received on bus line `i2ci_sda` are shifted in in synchronization with the clock pulses on `i2ci_scl` generated by the master device. The slave receiver does not generate the clock, but it can hold the serial clock line low when intervention of the LH is required (the `I2Ci.I2C_STAT[11]` ROVR bit) after a byte is received.

### 18.2.1.3.9 Bus Arbitration

If two or more master transmitters start a transmission on the same bus simultaneously, an arbitration procedure is invoked. This arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has

been overruled by a low signal, it switches to slave receiver mode, sets the arbitration lost flag (I2Ci.I2C\_STAT[0] AL bit), and generates the arbitration lost interrupt. Figure 18-9 shows arbitration between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

**Figure 18-9. Arbitration Between Master Transmitters**

#### 18.2.1.3.10 I<sup>2</sup>C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal i2ci\_scl. During arbitration, however, there are two or more master devices, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that the device that first generates a low period of the clock line overrules the other devices. At this high-low transition, the clock generators of the other devices are forced to start generating their own low periods. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, all clock generators must enter the wait state. In this way, a slave can slow down a fast master, and the slow device can create enough time to store a received byte or prepare a byte to be transmitted. Figure 18-10 shows clock synchronization.

**Figure 18-10. Synchronization of I<sup>2</sup>C Clock Generators**

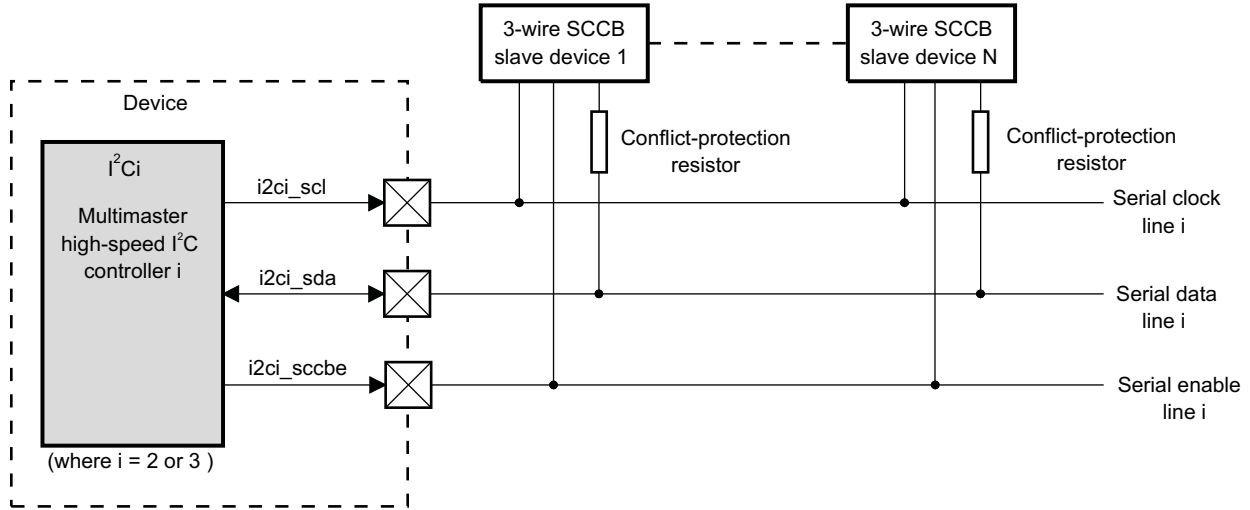

### 18.2.2 Multimaster High-Speed I<sup>2</sup>C Controllers in SCCB Mode

The SCCB is a 3-wire serial bus developed by Omnivision Technologies, Inc. The SCCB can also operate in a modified 2-wire serial mode. For details, see the SCCB specifications version 2.1 document at [http://www.ovt.com/pdfs/ds\\_note.pdf](http://www.ovt.com/pdfs/ds_note.pdf).

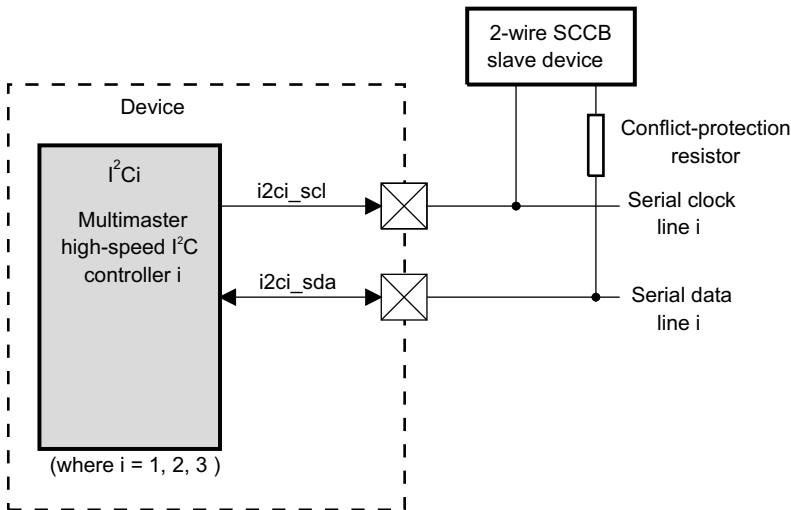

The multimaster HS I<sup>2</sup>C controllers support the 2-wire SCCB protocol in master mode. Only the I2C2 and I2C3 modules support the 3-wire SCCB protocol in master mode.

Figure 18-11 shows the multimaster HS I<sup>2</sup>C controllers and their related connections with 3-wire or 2-wire SCCB-compliant devices.

Figure 18-11. Multimaster HS I<sup>2</sup>C Controllers and Typical Connections to SCCB Devices

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

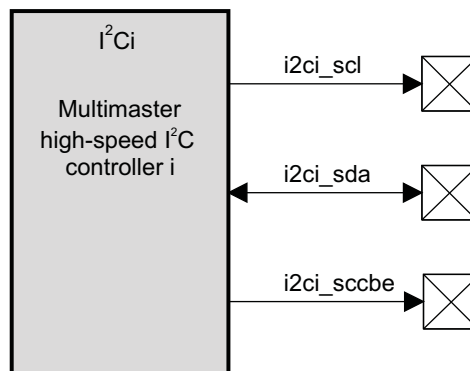

I2C-011

**Note:** Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

### 18.2.2.1 Multimaster HS I<sup>2</sup>C Controller Pins for Typical Connections in SCCB Mode

Figure 18-12 shows the multimaster HS I<sup>2</sup>C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

**Figure 18-12. Multimaster HS I<sup>2</sup>C Controller Interface Signals in SCCB Mode**

(where i = 1, 2, 3 and i2ci\_sccb\_e is not available for I2C1)

I2C-012

### 18.2.2.2 SCCB Interface Typical Connections

Table 18-2 lists the pins associated with the SCCB interface.

**Table 18-2. Input/Output**

Signal	I/O <sup>(1)</sup>	Description	Reset Value	I2Ci.I2C_CON[15] I2C_EN bit = 0
i2ci_scl	O	SCCB serial clock line <sup>(2)</sup> . Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccb_e <sup>(3)</sup>	O	SCCB enable line. Standard CMOS output buffer.	High	High

(1) I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

(2) This output signal is also used as re-timing input.

(3) This signal is used for the 3-wire SCCB protocol only.

**Note:** Because they share the same ball, the i2c2\_sccb\_e and i2c3\_sccb\_e signals are not available at the same time. For detailed information about pin configuration, see [Chapter 7, System Control Module](#).

The I2C1 module does not provide any i2c1\_sccb\_e signal at the chip boundary of the device; thus, this module does not support the 3-wire SCCB protocol

### 18.2.2.3 SCCB Typical Connection Protocol and Data Format

#### 18.2.2.3.1 Serial Transmission Timing Diagram

Figure 18-13 is the timing diagram of the 3-wire SCCB data transmission.

Figure 18-13. 3-wire SCCB Transmission Timing Diagram

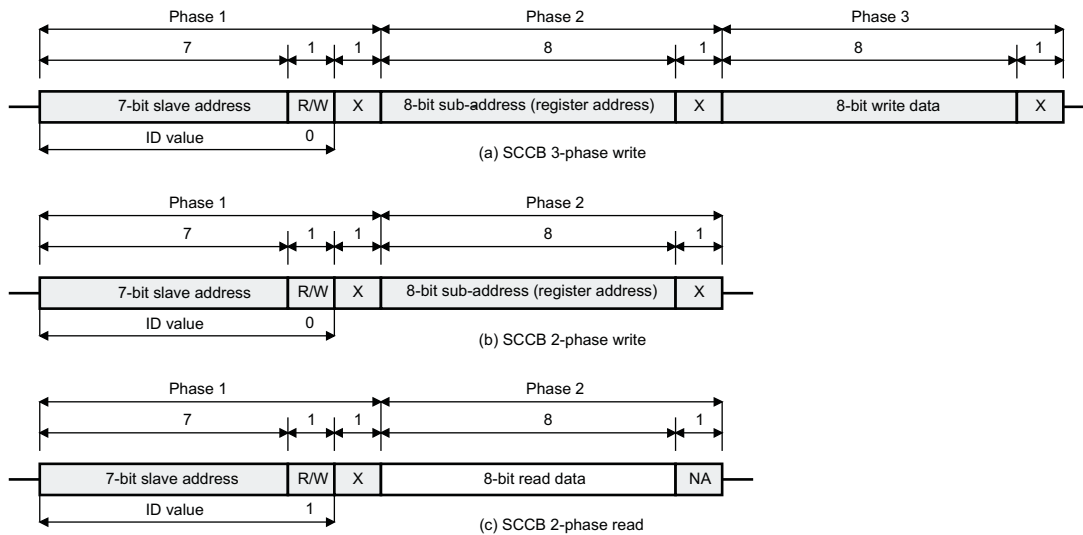

**Note:** When operating in 2-wire SCCB mode, the i2ci\_sccbce signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

#### 18.2.2.3.2 SCCB Transmission Data Formats

Figure 18-14 describes the data format of the three kinds of transmission.

Figure 18-14. SCCB Transmission Data Formats

R/W: 0 = Write, 1 = Read

X: don't care

NA: ninth bit of a read phase. This bit must be set to 1 by the master device.

I2C-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- **3-phase write transmission:** The 3-phase write transmission cycle (see (a) of [Figure 18-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).
- **2-phase write transmission:** The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 18-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).
- **2-phase read transmission:** Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of [Figure 18-14](#)) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

---

**Note:** A multimaster HS I<sup>2</sup>C controller configured in SCCB mode can perform two operations:

- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
  - Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
- 

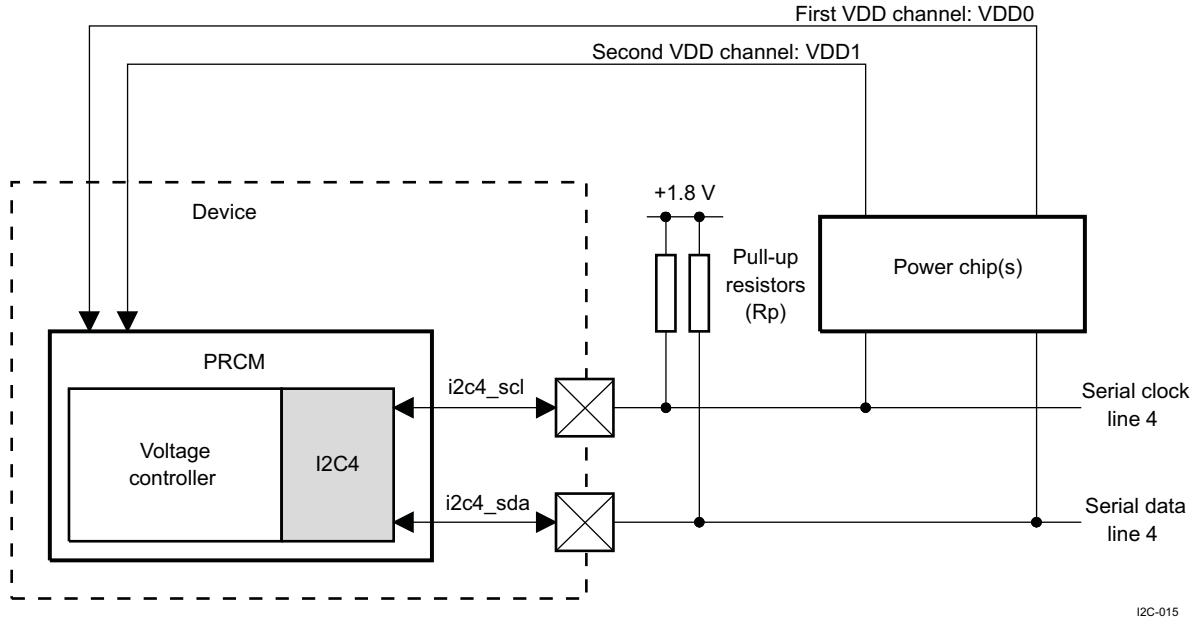

### 18.2.3 High-Speed I<sup>2</sup>C Controller for Communication With Power Chip(s)

The master transmitter HS I<sup>2</sup>C controller I2C4 interfaces between the and external power chip(s) for voltage control. This module is always configured as an I<sup>2</sup>C master transmitter; it does not support the SCCB protocol. For a definition of master transmitter mode, see [Section 18.2.1.3.5, Master Transmitter](#).

[Figure 18-15](#) shows a typical connection between the master transmitter HS I<sup>2</sup>C controller I2C4 of the device and external power chip(s).

Figure 18-15. Typical Connection Between the HS I<sup>2</sup>C Controller and Power Chip(s)

18.2.3.1 HS I<sup>2</sup>C Controller I2C4 Pins for Typical Connections

Figure 18-16 shows the HS I<sup>2</sup>C controller I2C4 pins used for typical connections with power chips.

Figure 18-16. HS I<sup>2</sup>C Controller I2C4 Interface Signals

18.2.3.2 HS I<sup>2</sup>C Controller I2C4 Interface Typical Connections

Table 18-3 lists the pins associated with the I<sup>2</sup>C interface of the HS I<sup>2</sup>C controller I2C4 of the device.

Table 18-3. Input/Output Description

Signal	I/O <sup>(1)</sup>	Description	Reset Value
i2c4_scl	I/O(OD)	I <sup>2</sup> C serial clock line <sup>(2)</sup> . Open-drain output buffer. Requires external Rp.	Hi-Z
i2c4_sda	I/O(OD)	I <sup>2</sup> C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z

(1) I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance  
 (2) This signal is also used as re-timing input.

**Note:** The I2C4 clock frequency in HS mode is equal to the SYS\_CLK clock frequency divided by 15.

### 18.2.3.3 I<sup>2</sup>C Typical Connections Protocol and Data Format for I2C4

#### 18.2.3.3.1 Serial Data Format

The serial data format is the same as described in [Section 18.2.1.3.1, Serial Data Format](#).

#### 18.2.3.3.2 Data Validity

The data validity is the same as described in [Section 18.2.1.3.2, Data Validity](#).

#### 18.2.3.3.3 S and P Conditions

The S and stop P conditions are the same as described in [Section 18.2.1.3.3, Start and Stop Conditions](#).

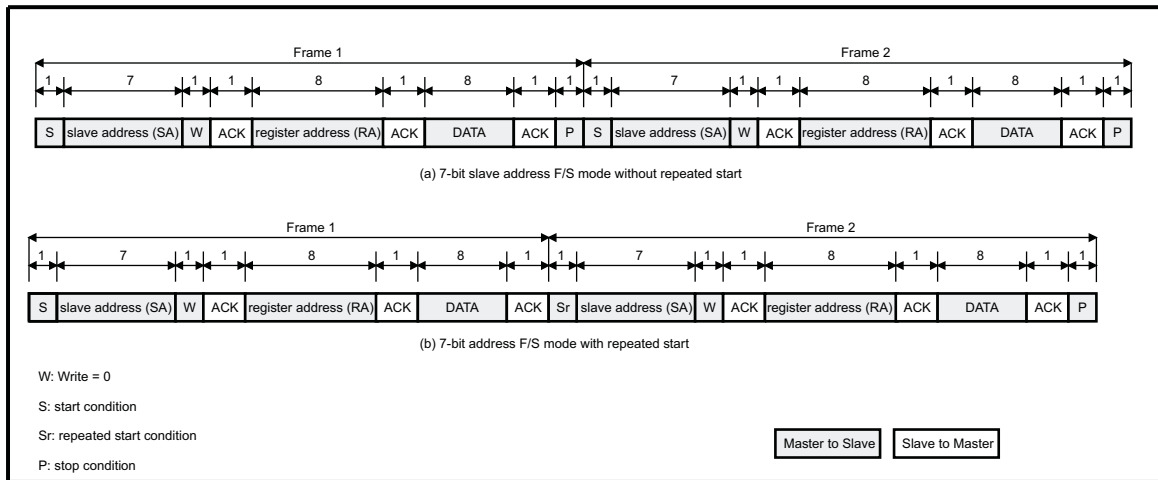

#### 18.2.3.3.4 Addressing

The master transmitter HS I<sup>2</sup>C controller I2C4 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

##### 18.2.3.3.4.1 Data Transfer Format in F/S Mode

[Figure 18-17](#) shows the I<sup>2</sup>C data transfer format in F/S mode for the I2C4 module.

**Figure 18-17. I<sup>2</sup>C Data Transfer Format in F/S Mode for the I2C4 Module**

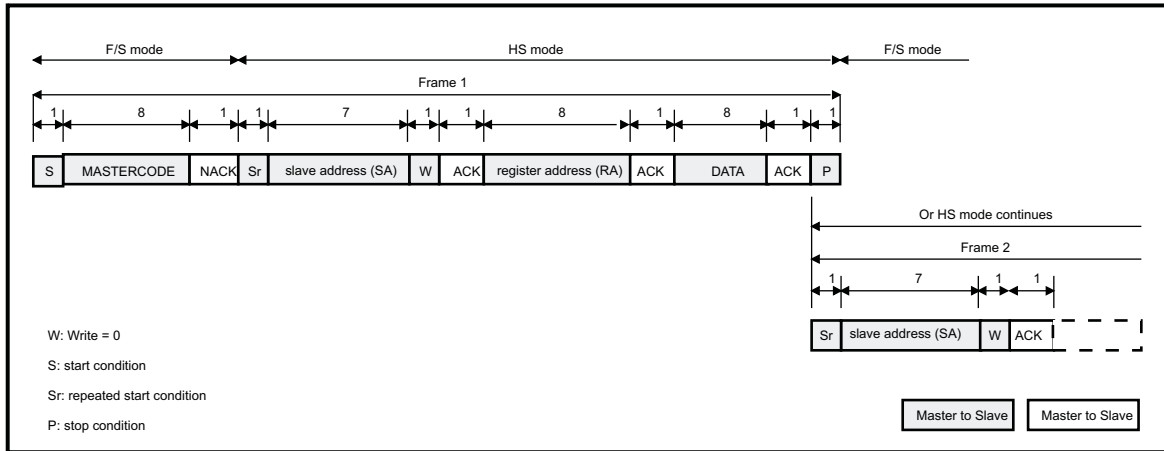

I2C-017

**18.2.3.3.4.2 Data Transfer Format in HS Mode**

Figure 18-18 shows the I<sup>2</sup>C data transfer format in HS mode for the I2C4 module.

**Figure 18-18. I<sup>2</sup>C Data Transfer Format in HS Mode for the I2C4 Module**

I2C-018

## 18.3 High-Speed I<sup>2</sup>C Controller Integration

Figure 18-19 shows the integration of the four HS I<sup>2</sup>C controllers in the device.

Figure 18-19. HS I<sup>2</sup>C Controller Integration

I2C-019

### 18.3.1 Clocking, Reset, and Power-Management Scheme

#### 18.3.1.1 Clocks

##### 18.3.1.1.1 Module Clocks

Each multimaster HS I<sup>2</sup>C controller is clocked with an independent functional clock of 96 MHz (I2Ci\_FCLK) and an interface clock (I2Ci\_ICLK) for interfacing with the L4-Core interconnect. These clocks are provided by the PRCM module.

The SYS\_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I<sup>2</sup>C controller I2C4. For detailed information about the module clocking, see [Chapter 4, Power, Reset, and Clock Management](#).

The interface clock can be enabled or disabled for each multimaster HS I<sup>2</sup>C controller by setting the following bits in the PRCM module:

- PRCM.CM\_ICLKEN1\_CORE[15] EN\_I2C1 bit for the I2C1 module
- PRCM.CM\_ICLKEN1\_CORE[16] EN\_I2C2 bit for the I2C2 module
- PRCM.CM\_ICLKEN1\_CORE[17] EN\_I2C3 bit for the I2C3 module

The functional clock can be enabled or disabled for each multimaster HS I<sup>2</sup>C controller by setting the following bits in the PRCM module:

- PRCM.CM\_FCLKEN1\_CORE[15] EN\_I2C1 bit for the I2C1 module
- PRCM.CM\_FCLKEN1\_CORE[16] EN\_I2C2 bit for the I2C2 module
- PRCM.CM\_FCLKEN1\_CORE[17] EN\_I2C3 bit for the I2C3 module

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I<sup>2</sup>C prescaler block. The prescaler block consists of the I2Ci.I2C\_PSC[7:0] PSC bit field (where  $i = 1, 2, 3$ ) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of  $I2Ci\_FCLK / (I2Ci\_I2C\_PSC[7:0] \text{ PSC bit field value} + 1)$ , where  $i = 1, 2, 3$ .

---

**Note:** The I2C4.I2C\_PSC[7:0] PSC bit field of the I2C4 module is not accessible by software. For details about the bit rates available for the I2C4 module, see [Section 18.4.7](#).

---

### 18.3.1.2 Power Management

#### 18.3.1.2.1 Module Power Saving

This section describes power-saving techniques for the multimaster HS I<sup>2</sup>C controllers. To conserve power, when no activity is detected on the L4-Core interconnect interface of the module, each of these modules supports an automatic idle mode that is enabled or disabled by setting the I2Ci.I2C\_SYSC[0] AUTOIDLE bit.

When this bit is asserted (set to 1), if no activity is detected on the L4-Core interface, the automatic idle mode is enabled and the interface clock I2Ci\_ICLK is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface of the module, the clock restarts with no latency penalty. After reset, the automatic idle mode is disabled; thus, this mode must be enabled by software for reduced power consumption.

#### 18.3.1.2.2 System Power Management

As part of the system-wide power-management scheme, each multimaster HS I<sup>2</sup>C controller supports a communication protocol with the PRCM module to request the module to enter a low-power mode. When a module acknowledges a low-power mode request from the PRCM module, the interface and/or the functional clocks are gated off at the PRCM clock generator. Because the clocks are disabled at the source, the low-power mode offers lower power consumption than the internal clock autogating method used by local power management.

The PRCM.CM\_ICLKEN1\_CORE[15] EN\_I2C1, PRCM.CM\_ICLKEN1\_CORE[16] EN\_I2C2, and PRCM.CM\_ICLKEN1\_CORE[17] EN\_I2C3 bits in the PRCM module control the interface clocks of the I2C1, I2C2, and I2C3 modules, respectively.

The PRCM.CM\_FCLKEN1\_CORE[15] EN\_I2C1, PRCM.CM\_FCLKEN1\_CORE[16] EN\_I2C2, and PRCM.CM\_FCLKEN1\_CORE[17] EN\_I2C3 bits in the PRCM module control the functional clocks of the I2C1, I2C2, and I2C3 modules, respectively.

For details about clock enabling/disabling in the PRCM module, see [Chapter 4, Power, Reset, and Clock Management](#).

Each multimaster HS I<sup>2</sup>C controller can be configured through the I2Ci.I2C\_SYSC[4:3] IDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (I2Ci.I2C\_SYSC[4:3] IDLEMODE bit field = b00): The module immediately enters idle mode on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go to idle state.
- No-idle mode (I2Ci.I2C\_SYSC[4:3] IDLEMODE bit field = b01): The module never enters idle mode.
- Smart-idle mode (I2Ci.I2C\_SYSC[4:3] IDLEMODE bit field = b10): After receiving a low-power-mode request from the PRCM module, the module enters idle mode only after all asserted output interrupts are acknowledged and there is no pending internal event.

---

**Note:** The value I2Ci.I2C\_SYSC[4:3] IDLEMODE bit field = b11 must not be used.

---

Table 18-4 describes the multimaster HS I<sup>2</sup>C controller power management modes.

**Table 18-4. Multimaster HS I<sup>2</sup>C Controller Power Management Modes**

Power management mode requested by the PRCM module	I2Ci.I2C_SYSC[4:3] IDLEMODE bit field value (where i = 1, 2, 3)
Force-idle	b00
No-idle	b01
Smart-idle	b10
Reserved (not used)	b11

The PRCM module gates the interface and/or the functional clocks after receiving the acknowledgment of the I2Ci module (where i = 1, 2, 3). The I2Ci.I2C\_SYSC[9:8] CLOCKACTIVITY bit field indicates the state of the interface and functional clocks of the module when in idle mode. Table 18-5 lists the value of the I2Ci.I2C\_SYSC[9:8] CLOCKACTIVITY bit field and indicates the state of the interface and functional clocks at the PRCM clock generator output in idle mode.

**Table 18-5. State of the Interface and Functional Clocks When the Module is in Idle Mode**

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field value (where i = 1, 2, 3)	Functional Clock	Interface Clock
b00	OFF	OFF
b01	OFF	ON
b10	ON	OFF
b11	ON	ON

---

**Note:** The PRCM.CM\_AUTOIDLE1\_CORE[15] AUTO\_I2C1, PRCM.CM\_AUTOIDLE1\_CORE[16] AUTO\_I2C2, and PRCM.CM\_AUTOIDLE1[17] AUTO\_I2C3 bits control, for each multimaster HS I<sup>2</sup>C controller, whether the L4-Core interconnect interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see [Chapter 4, Power, Reset, and Clock Management](#)).

---

---

**Note:** The voltage controller, in which the HS I<sup>2</sup>C controller I2C4 is implemented, has no idle request/acknowledge mechanism. The idle modes for the voltage controller are directly managed by the PRM module. For details, see [Chapter 4, Power, Reset, and Clock Management](#).

---

18.3.1.2.3 Wake-Up Capability

Each multimaster HS I<sup>2</sup>C controller I2Ci can wake up the system by generating a wake-up request through the I2Ci\_WAKE signal connected to the PRCM module.

The wake-up request is composed of the merge of all wake-up events. Each wake-up event can be separately enabled or disabled by setting the corresponding bit in the I2Ci.I2C\_WE register.

The global wake-up capability of the module can be enabled or disabled by setting the I2Ci.I2C\_SYSC[2] ENAWAKEUP bit (1: enabled, 0: disabled).

Figure 18-20 shows the wake-up generation flow.

Figure 18-20. Wake-up Generation Flow

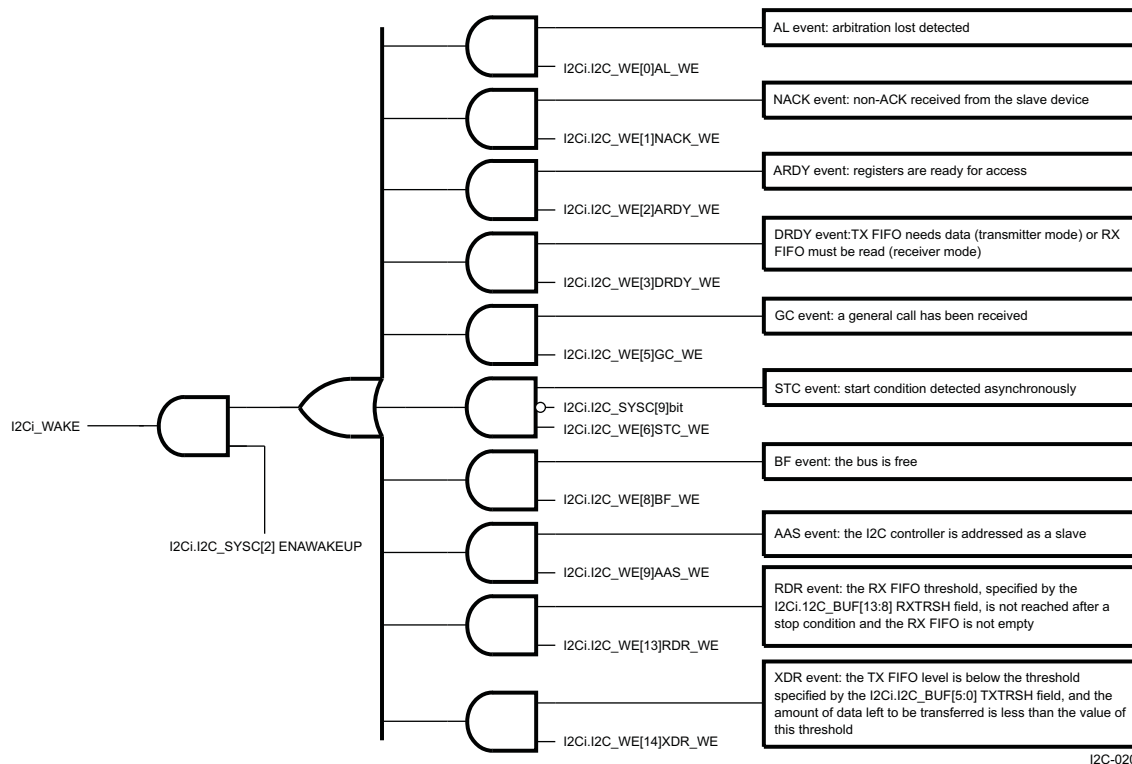

Table 18-6 lists all wake-up events with the corresponding enable/disable bit in the I2Ci.I2C\_WE register.

Table 18-6. Wake-up Events

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit <sup>(1)</sup>	Event Generated When:
AL event	I <sup>2</sup> C mode only	I2Ci.I2C_WE[0] AL_WE	The I2Ci module in the device loses the arbitration of the I <sup>2</sup> C bus in master transmitter mode.
NACK event	I <sup>2</sup> C mode only	I2Ci.I2C_WE[1] NACK_WE	A nonacknowledgment has been generated on the I <sup>2</sup> C bus, indicating a transmission error.
ARDY event	I <sup>2</sup> C receive mode and SCCB read mode	I2Ci.I2C_WE[2] ARDY_WE	The current transaction is finished and the module registers can be accessed.
DRDY event	I <sup>2</sup> C and SCCB modes	I2Ci.I2C_WE[3] DRDY_WE	The TX FIFO needs some data to be transferred or the RX FIFO must be read.
GC event	I <sup>2</sup> C mode only	I2Ci.I2C_WE[5] GC_WE	A general call is received on the I <sup>2</sup> C bus.

<sup>(1)</sup> To enable the corresponding wake-up event generation, set the bit to 1. To disable the corresponding wake-up event generation, set the bit to 0.

**Table 18-6. Wake-up Events (continued)**

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit <sup>(1)</sup>	Event Generated When:
STC event <sup>(2)</sup>	I <sup>2</sup> C mode only	I2Ci.I2C_WE[6] STC_WE	A start (S) condition is detected on the I <sup>2</sup> C bus. <sup>(3)</sup>
BF event	I <sup>2</sup> C and SCCB modes	I2Ci.I2C_WE[8] BF_WE	The bus is free and the LH can initiate its own transfer.
AAS event	I <sup>2</sup> C mode only	I2Ci.I2C_WE[9] AAS_WE	An external master I <sup>2</sup> C device addresses the module of the device to inform the LH that it can check which of its own addresses was used by the external master I <sup>2</sup> C device to access the module of the device.
RDR event	I <sup>2</sup> C receive mode only	I2Ci.I2C_WE[13] RDR_WE	The module, configured as a receiver, has detected a stop (P) condition on the I <sup>2</sup> C bus and the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached and the RX FIFO is not empty. This allows the module to inform the LH that it can check the amount of data to be transferred from the RX FIFO.
XDR event	I <sup>2</sup> C master transmit mode only	I2Ci.I2C_WE[14] XDR_WE	The TXFIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the amount of data left to be transferred is less than this threshold. This allows the module to inform the LH that it can check the amount of data to be written to the TX FIFO.

<sup>(2)</sup> Wake-up event asynchronously detected.

<sup>(3)</sup> This event must not be enabled if the functional clock cannot be disabled.

---

**Note:** With the exception of the STC event, the functional clock must be active for wake-up event detection to occur. The HS I<sup>2</sup>C controller I2C4 has no wake-up capability.

---

### 18.3.1.3 Resets

#### 18.3.1.3.1 Hardware Reset

The three multimaster HS I<sup>2</sup>C controllers receive their reset signal CORE\_RST (the reset signal of the CORE power domain) from the PRCM module.

The master transmitter HS I<sup>2</sup>C controller I2C4 gets its reset signal PRM\_RSTPWON from the reset manager in the PRCM module.

#### 18.3.1.3.2 Software Reset

Each multimaster HS I<sup>2</sup>C controller supports the software reset by accessing the I2Ci.I2C\_SYSC[1] SRST bit (1: reset, 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C\_SYSS[0] RDONE bit (1: reset is done, 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2Ci.I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2Ci.I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

**Note:** The I2Ci.I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multimaster HS I<sup>2</sup>C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I<sup>2</sup>C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I<sup>2</sup>C controller.

The I2Ci.I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

#### 18.3.1.4 Power Domain

The three multimaster HS I<sup>2</sup>C controllers are connected to the CORE power domain, whereas the HS I<sup>2</sup>C controller I2C4 belongs to the WKUP power domain.

### 18.3.2 Hardware Requests

#### 18.3.2.1 DMA Requests

Each multimaster HS I<sup>2</sup>C controller can generate two DMA requests to the system DMA (sDMA) controller. [Table 18-7](#) lists the DMA requests with mapping on the sDMA controller.

**Table 18-7. Multimaster HS I<sup>2</sup>C Controller DMA Requests**

Name	Source	Destination (sDMA controller)	Description
I2C1_DMA_TX	I2C1	S_DMA_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	S_DMA_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	S_DMA_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	S_DMA_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	S_DMA_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	S_DMA_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register

**Note:** The HS I<sup>2</sup>C controller I2C4 does not generate any DMA request.

#### 18.3.2.2 Interrupt Requests

Each multimaster HS I<sup>2</sup>C controller can generate an interrupt I2Ci\_IRQ to the MPU subsystem. [Table 18-8](#) lists the interrupt requests with the mapping on the MPU interrupt controller.

**Table 18-8. Multimaster HS I<sup>2</sup>C Controller Interrupt Requests**

Name	Source	Destination (MPU interrupt controller)
I2C1_IRQ	I2C1	M_IRQ_56
I2C2_IRQ	I2C2	M_IRQ_57
I2C3_IRQ	I2C3	M_IRQ_61

An event can generate an interrupt request when the corresponding mask bit in the I2Ci.I2C\_IE register is set to 1. Table 18-9 summarizes the events causing the generation of an interrupt request.

**Table 18-9. Multimaster HS I<sup>2</sup>C Controller Interrupt Events**

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
AL event	I <sup>2</sup> C mode only	I2Ci.I2C_STAT [0] AL	I2Ci.I2C_IE[0] AL_IE	Two or more I <sup>2</sup> C master devices initiate a transfer and the I <sup>2</sup> C module I2Ci in the device loses arbitration of the I <sup>2</sup> C bus.
NACK event	I <sup>2</sup> C mode only	I2Ci.I2C_STAT [1] NACK	I2Ci.I2C_IE[1] NACK_IE	A nonacknowledgment has been received. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1).
ARDY event	I <sup>2</sup> C and SCCB modes	I2Ci.I2C_STAT [2] ARDY	I2Ci.I2C_IE[2] ARDY_IE	One of the following cases occurs: <ul style="list-style-type: none"> <li>In I<sup>2</sup>C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0, and the RX FIFO is empty.</li> <li>In I<sup>2</sup>C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is set to 1 and the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0.</li> <li>In I<sup>2</sup>C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is cleared to 0 and the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0.</li> <li>In I<sup>2</sup>C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0, and the RX FIFO is empty.</li> <li>In I<sup>2</sup>C slave transmitter mode, a stop or start (S) condition is received from the external I<sup>2</sup>C master device.</li> <li>In I<sup>2</sup>C slave receiver mode, a stop or start (S) condition is received from the external I<sup>2</sup>C master device and the RX FIFO is empty.</li> <li>In SCCB master transmitter or receiver mode, a stop (P) condition is detected.</li> </ul>
RRDY event	I <sup>2</sup> C receive mode and SCCB read mode	I2Ci.I2C_STAT [3] RRDY	I2Ci.I2C_IE[3] RRDY_IE	The RX FIFO level is above the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XRDY event	I <sup>2</sup> C transmit mode and SCCB write mode	I2Ci.I2C_STAT [4] XRDY	I2Ci.I2C_IE[4] XRDY_IE	The module requires new data to be served. A master transmitter module requests new data when the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the required amount of data to be transmitted specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field is greater than the threshold. A slave transmitter requests new data when the TX FIFO is below the threshold (if the I2Ci.I2C_BUF[5:0] XTRSH field value is greater than 1), or when there is a read request from the external master device (for each acknowledge received from the master) when the I2Ci.I2C_BUF[5:0] XTRSH field value is 1.
GC event	I <sup>2</sup> C mode only	I2Ci.I2C_STAT [5] GC	I2Ci.I2C_IE[5] GC_IE	The module detects a general call on the I <sup>2</sup> C bus (all bits of the address cleared to 0).
STC event	I <sup>2</sup> C mode only	I2Ci.I2C_STAT [6] STC	I2Ci.I2C_IE[6] STC_IE	The module is in idle mode and a start (S) condition is asynchronously detected on the I <sup>2</sup> C bus and signaled with a wakeup. When the active mode is restored and the interrupt generated, this bit indicates the reason for the wakeup. See <sup>(1)</sup> .

<sup>(1)</sup> The interrupt request generation on an STC event must be enabled only if the module is configured to allow the possibility of switching off the functional clock while in idle state (the I2Ci.I2C\_SYSC[9:8] CLOCKACTIVITY field set to b00 or b01). The first transfer (corresponding to the detected start (S) condition) is lost, and is used only to restore the active mode of the module. On the I<sup>2</sup>C bus, the external master that generated the transfer detects this behavior as a nonacknowledge to the address phase and may possibly restart the transfer.

**Table 18-9. Multimaster HS I<sup>2</sup>C Controller Interrupt Events (continued)**

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
AERR event	I <sup>2</sup> C and SCCB modes	I2Ci.I2C_STAT [7] AERR	I2Ci.I2C_IE[7] AERR_IE	A write access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the TX FIFO is full or a read access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the RX FIFO is empty. When the RX FIFO is empty, the read of the RX FIFO returns the previous read data value. When the TX FIFO is full, a write in the TX FIFO is ignored.
BF event	I <sup>2</sup> C and SCCB modes	I2Ci.I2C_STAT [8] BF	I2Ci.I2C_IE[8] BF_IE	The I <sup>2</sup> C bus becomes free (after a transfer is ended on the bus and a stop (P) condition is detected).
AAS event	I <sup>2</sup> C mode only	I2Ci.I2C_STAT [9] AAS	I2Ci.I2C_IE[9] AAS_IE	The module has recognized its own slave address or an alternate Own Address, or a general call (all address bits cleared to 0).
RDR event	I <sup>2</sup> C receive mode only	I2Ci.I2C_STAT [13] RDR	I2Ci.I2C_IE[13] RDR_IE	The module is configured as a receiver, a stop (P) condition was received on the I <sup>2</sup> C bus, and the RX FIFO level is below the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XDR event	I <sup>2</sup> C master transmit mode only	I2Ci.I2C_STAT [14] XDR	I2Ci.I2C_IE[14] XDR_IE	The module is configured as a master transmitter, the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1), and the amount of data still to be transferred is less than this threshold.

When an interrupt request is generated, the software must read the I2Ci.I2C\_STAT register to check which event caused the interrupt request generation, process accordingly, and acknowledge each processed event by writing 1 to the corresponding bit in the I2Ci.I2C\_STAT register.

**Note:** The I2Ci.I2C\_STAT[9] AAS status bit, corresponding to the AAS event, can be cleared in two ways:

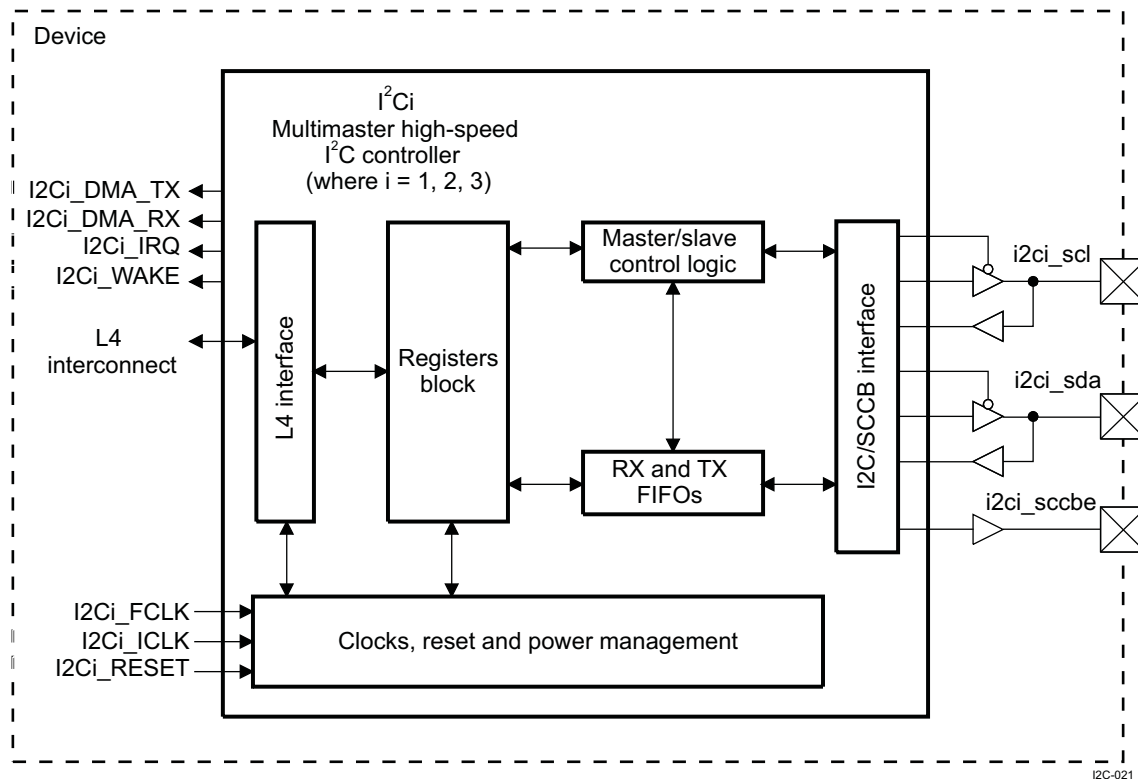

- If the I2Ci.I2C\_IE[9] AAS\_IE bit is set to 1 (interrupt generation enabled), the status bit is cleared by writing 1 to the I2Ci.I2C\_STAT[9] AAS status bit
- If the I2Ci.I2C\_IE[9] AAS\_IE bit is cleared to 0 (interrupt generation disabled), the status bit is cleared when a new start or stop (P) condition is detected on the I<sup>2</sup>C bus.

## 18.4 High-Speed I<sup>2</sup>C Controller Functional Description

### 18.4.1 Block Diagram

Figure 18-21 is a functional block diagram of the multimaster I<sup>2</sup>C HS controller.

Figure 18-21. Multimaster HS I<sup>2</sup>C Controller Block Diagram

**Note:** The i2c1\_sccb\_e signal is not available.

The three multimaster HS I<sup>2</sup>C controllers can be configured in F/S I<sup>2</sup>C mode, in HS I<sup>2</sup>C mode, or in SCCB mode. The operation mode is selected by configuring the I2Ci.I2C\_CON[13:12] OPMODE field.

Table 18-10 lists the available operation modes.

Table 18-10. Operation Mode Selection

Operation Mode	I2Ci.I2C_CON[13:12] OPMODE field value
Fast/standard (F/S) I <sup>2</sup> C	0x0
High-speed (HS) I <sup>2</sup> C	0x1
SCCB	0x2
Reserved (not used)	0x3

### 18.4.2 Transmit Mode in I<sup>2</sup>C Mode

This mode is available for master or slave. The master and slave modes are configurable with the I2Ci.I2C\_CON[10] MST bit (0: slave mode, 1: master mode).

In master mode, the transmit mode is configured by setting the I2Ci.I2C\_CON[9] TRX bit to 1. The MPU subsystem puts the data to transmit in the TX FIFO by writing to the I2Ci.I2C\_DATA[7:0] DATA bit field.

The transmitter can write new data to this register when the I2Ci.I2C\_STAT[4] XRDY bit is set to 1, or when the I2Ci.I2C\_STAT[14] XDR bit is set to 1 according to the draining mechanism description.

A master transmitter requests new data if the I2Ci.I2C\_CNT[15:0] DCOUNT bit field value is not 0. A slave transmitter requests new data if a read is performed by the external master.

---

**Note:** The HS I2C controller I2C4 is configured in master transmitter mode, and its configuration cannot be changed.

---

### 18.4.3 Receive Mode in I<sup>2</sup>C Mode

This mode is available for master or slave. In master mode, it is configured by clearing the I2Ci.I2C\_CON[9] TRX bit to 0.

The MPU subsystem can read new data from the I2Ci.I2C\_DATA[15:0] DCOUNT bit field when the I2Ci.I2C\_STAT[3] RRDY bit is set to 1, or when the I2Ci.I2C\_STAT[13] RDR bit is set according to the draining mechanism description.

Each time the I2Ci.I2C\_STAT[3] RRDY bit is set to 1, if the interrupt is enabled (the I2Ci.I2C\_IE[3] RRDY\_IE bit must be set to 1), the I<sup>2</sup>C controller generates an interrupt to the MPU subsystem.

---

**Note:** In interrupt mode, the MPU subsystem must read this bit after each read in the I2Ci.I2C\_DATA register to ensure that no other data is waiting for the FIFO to be read. For a new interrupt to be received, the I2Ci.I2C\_STAT[3] RRDY bit must be cleared in the interrupt routine.

If the DMA receive mode is enabled (the I2Ci.I2C\_BUF[15] RDMA\_EN bit is set), this bit is forced to 0 and no interrupt is generated; instead, a DMA RX request to the sDMA controller is generated.

---

### 18.4.4 FIFO Management

Each multimaster HS I<sup>2</sup>C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

Table 18-11 lists the depth of these FIFOs, depending on the instance of the I<sup>2</sup>C controller.

**Table 18-11. RX and TX FIFO Depths**

I <sup>2</sup> C Controller Instance	RX and TX FIFO Depth (in bytes)
I2C1	8
I2C2	8
I2C3	64

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C\_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

#### 18.4.4.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C\_IE register), the processor is informed of the receiver and transmitter status by an interrupt signal. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C\_BUF[13:8] RTRSH field value + 1 for the RX FIFO or the I2Ci.I2C\_BUF[5:0] XTRSH field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I<sup>2</sup>C controller module in receive mode and/or from any source to the I<sup>2</sup>C controller FIFO in transmit mode).

Figure 18-22 and Figure 18-23 show receive and transmit operations, respectively, from a FIFO management point of view.

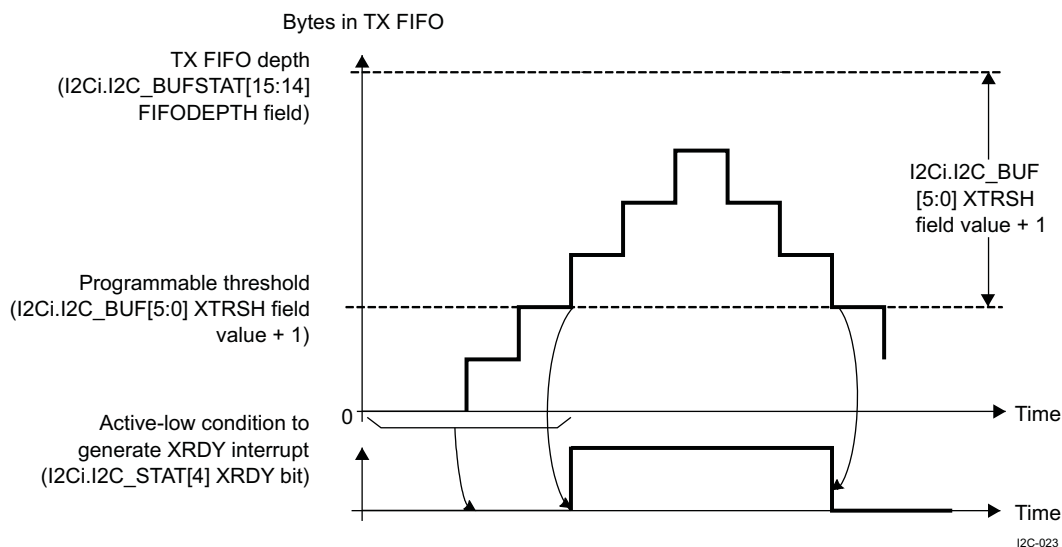

**Figure 18-22. Receive FIFO Interrupt Request Generation**

I2C-022

In [Figure 18-22](#), the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C\_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C\_BUF[13:8] RTRSH field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Note:** In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C\_BUF[13:8]RTRSH and I2Ci.I2C\_BUF[5:0]XTRSH fields to 0x0.

**Figure 18-23. Transmit FIFO Interrupt Request Generation**

I2C-023

In [Figure 18-23](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by writing 1 in the I2Ci.I2C\_STAT[4] XRDY bit after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY/RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is no longer met.
- When detecting an interrupt request (XRDY/RRDY type), the LH can be programmed to write/read the number of data bytes specified by the corresponding FIFO threshold (I2Ci.I2C\_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C\_BUF[13:8] RTRSH field value + 1 for the RX threshold). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY/RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 18.4.4.4).

---

**Note:** In slave transmit mode (the I2Ci.I2C\_CON[10] MST bit is cleared and the I2Ci.I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C\_BUF[6] TXFIFO\_CLR bit.

---

#### 18.4.4.2 FIFO Polling Mode Operation

In FIFO polled mode (the I2Ci.I2C\_IE[4] XRDY\_IE and I2Ci.I2C\_IE[3] RRDY\_IE bits are disabled, and the I2Ci.I2C\_BUF[15] RDMA\_EN and I2Ci.I2C\_BUF[7] XDMA\_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C\_STAT[4] XRDY and the I2Ci.I2C\_STAT[3] RRDY bits (the I2Ci.I2C\_STAT[13] RDR and I2Ci.I2C\_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C\_STAT[4] XRDY and I2Ci.I2C\_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of the FIFO interrupt mode operation.

#### 18.4.4.3 FIFO DMA Mode Operation (I<sup>2</sup>C Mode Only)

In receive mode, a DMA request is generated by the I2Ci\_DMA\_RX signal as soon as the RX FIFO exceeds its threshold level (I2Ci.I2C\_BUF[13:8] RTRSH field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA controller.

Figure 18-24 shows the DMA request generation in receive mode.

**Figure 18-24. Receive FIFO DMA Request Generation**

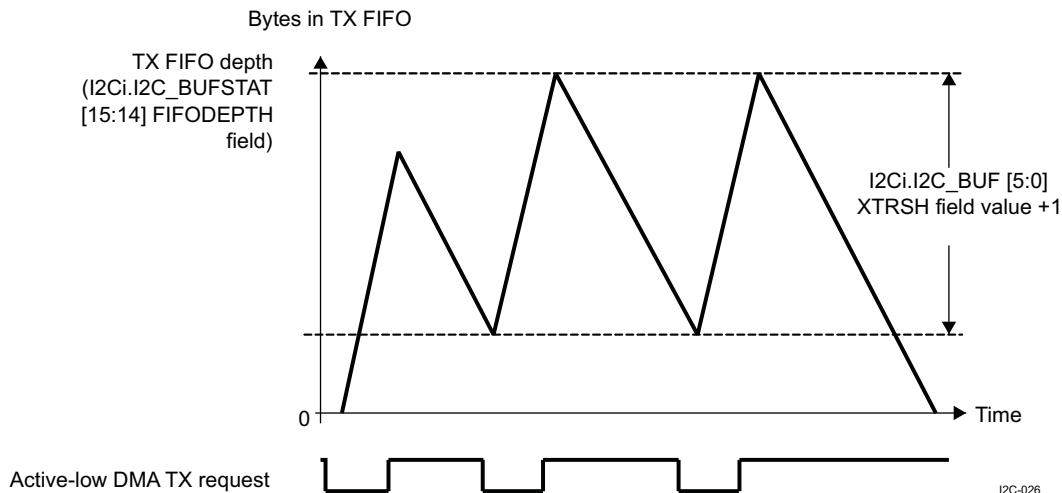

I2C-024

In transmit mode, a DMA request is automatically asserted by the I2Ci\_DMA\_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (I2Ci.I2C\_BUF[5:0] XTRSH field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 18-25 and Figure 18-26 show the DMA TX transfers with different values for the I2Ci.I2C\_BUF[5:0] XTRSH field.

**Figure 18-25. Transmit FIFO Request Generation (High Threshold)**

**Figure 18-26. Transmit FIFO Request Generation (Low Threshold)**

**Note:** In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C\_BUF[13:8]RTRSH and I2Ci.I2C\_BUF[5:0]XTRSH fields to 0x0.

#### 18.4.4.4 Draining Feature (I<sup>2</sup>C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (I2Ci.I2C\_BUF[13:8] RTRSH field value + 1 for the RX threshold and I2Ci.I2C\_BUF[5:0] XTRSH field value + 1 for the TX threshold). It also offers the possibility of transferring the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C\_STAT[7] AERR status bit.

The draining mechanism generates an interrupt using the I2Ci.I2C\_STAT[13] RDR or the I2Ci.I2C\_STAT[14] XDR status bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT or I2Ci.I2C\_BUFSTAT[5:0] TXSTAT fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (I2Ci.I2C\_BUF[13:8] RTRSH field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and there is still data in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C\_STAT[13] RDR status bit) is asserted to inform the LH that it can read the amount of data in the FIFO (the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT field). The LH performs a number of data read accesses equal to the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT field value (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C\_BUF[5:0] XTRSH field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C\_STAT[14] XDR status bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT field). The LH must write the required number of data bytes specified by the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately skip the checking of the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT and I2Ci.I2C\_BUFSTAT[13:8] RXSTAT field values, because it can obtain this information internally (by computing the the I2Ci.I2C\_CNT[15:0] DATACOUNT field value modulo I2Ci.I2C\_BUF[13:8] RTRSH or I2Ci.I2C\_BUF[5:0] XTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C\_IE[14] XDR\_IE or I2Ci.I2C\_IE[13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C\_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C\_BUF[13:8] RTRSH field value + 1 for the RX threshold).

#### **18.4.5 Programmable Multislave Channel Feature (I<sup>2</sup>C Mode Only)**

This feature allows each multimaster HS I<sup>2</sup>C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C\_OAx registers (with x = 0, 1, 2, 3). An additional register (I2Ci.I2C\_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I<sup>2</sup>C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C\_CON[7] XOA0, I2Ci.I2C\_CON[6] XOA1, I2Ci.I2C\_CON[5] XOA2, or I2Ci.I2C\_CON[4] XOA3).

#### **18.4.6 Automatic Blocking of the I<sup>2</sup>C Clock Feature (I<sup>2</sup>C Mode Only)**

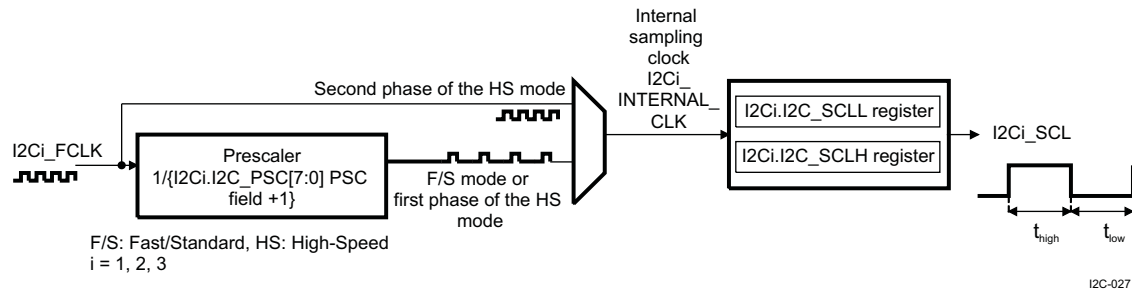

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the slave addressing phase, when the I<sup>2</sup>C controller is addressed by an external master device using a certain Own Address.

The release of the I<sup>2</sup>C clock (i2ci\_scl signal, with i = 1, 2, 3) can be performed independently for each Own Address (I2Ci.I2C\_OAi registers, with i = 0, 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C\_SBLOCK register.

### 18.4.7 Clocking

Figure 18-27 shows the I<sup>2</sup>C clock generation of the HS I<sup>2</sup>C controllers.

**Figure 18-27. I<sup>2</sup>C Clock Generation**

Each multimaster HS I<sup>2</sup>C controller uses the I2Ci\_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci\_INTERNAL\_CLK is generated by dividing the functional clock by (I2Ci.I2C\_PSC[7:0] PSC field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci\_SCL signal is determined by the I2Ci.I2C\_SCLL[7:0] SCLL field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C\_SCLL[15:8] HSSCLL field in the second phase of HS mode.

The high time of the I2Ci\_SCL signal is determined by the I2Ci.I2C\_SCLH[7:0] SCLH field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C\_SCLH[15:8] HSSCLH field in the second phase of HS mode.

Table 18-12 lists the  $t_{LOW}$  and  $t_{high}$  values in master mode only (in slave mode, the I<sup>2</sup>C controller does not generate the I<sup>2</sup>C clock).

**Table 18-12.  $t_{LOW}$  and  $t_{high}$  Values of the I<sup>2</sup>C Clock**

Mode	I2Ci_INTERNAL_CLK	$t_{LOW}$	$t_{high}$
F/S, SCCB, or HS first phase	$I2Ci\_FCLK / (I2Ci.I2C\_PSC[7:0] \text{ PSC field} + 1)$	$(I2Ci.I2C\_SCLL[7:0] \text{ SCLL field value} + 7) \times I2Ci\_INTERNAL\_CLK \text{ period}$	$(I2Ci.I2C\_SCLH[7:0] \text{ SCLH field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$
HS second phase	I2Ci_FCLK	$(I2Ci.I2C\_SCLL[15:8] \text{ HSSCLL field value} + 7) \times I2Ci\_INTERNAL\_CLK \text{ period}$	$(I2Ci.I2C\_SCLH[15:8] \text{ HSSCLH field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$

**Note:** The equations in Table 18-12 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I<sup>2</sup>C controller outputs. Actual flow and thigh periods may vary, depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

**Note:** For HS mode, both the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLL[7:0] SCLL fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, both the I2Ci.I2C\_SCLH[15:8] HSSCLH and I2Ci.I2C\_SCLH[7:0] SCLH fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

**CAUTION**

During active mode (I2Ci.I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2Ci.I2C\_SCLL and I2Ci.I2C\_SCLH registers. Changes may result in unpredictable behavior.

**Note:** Each multimaster HS I<sup>2</sup>C controller can be used with an internal secondary pullup. This pullup is mandatory when the I<sup>2</sup>C controller is configured in HS mode for a bit rate of 3.4M bps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through the CONTROL.CONTROL\_DEVCONF1[12] I2C1HSMaster bit for I2C1, the CONTROL.CONTROL\_DEVCONF1[13] I2C2HSMaster bit for I2C2, and the CONTROL.CONTROL\_DEVCONF1[14] I2C3HSMaster bit for I2C3.

The maximum bit rate specified by the SCCB specifications is 100K b/s.

### 18.4.8 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S and SCCB operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci\_INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C\_PSC[7:0] PSCbit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C\_PSC[7:0] PSC bit field.

### 18.4.9 System Test Mode

A system test mode is available for multimaster HS I<sup>2</sup>C controller module testing. This mode is enabled by setting the I2Ci.I2C\_SYSTEST[15] ST\_EN to 1. When this bit is cleared to 0, the I<sup>2</sup>C controller is configured in normal operation mode.

In system test mode, the I2Ci\_SYSTEST[13:12] TMODE bit field selects the type of test. Table 18-13 lists the tests available for the multimaster HS I<sup>2</sup>C controllers.

**Table 18-13. List of tests for the Multimaster HS I<sup>2</sup>C Controllers**

I2Ci.I2C_SYSTEST[13:12] TMODE field value	Test	Description
b00	Functional mode	Normal operation mode
b01	Reserved (not used)	
b10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
b11	Loop-back mode + i2ci_scl/ i2ci_sda/ i2ci_sccb input/output	In the master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccb lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits.

**Note:** When the I2Ci.I2C\_SYSTEST[13:12] TMODE field = b11, the I<sup>2</sup>C controller must be configured in I<sup>2</sup>C F/S (I2Ci.I2C\_CON[13:12] OPMODE = b00) or I<sup>2</sup>C HS mode (I2Ci.I2C\_CON[13:12] OPMODE = b01). The loop-back mode is not available in SCCB mode (I2Ci.I2C\_CON[13:12] OPMODE = b10).

---

**Note:** In normal operation mode (I2Ci.I2C\_SYSTEST[15] ST\_EN clear to 0), the I2Ci.I2C\_SYSTEST[4:0] bits that control the i2ci\_scl, i2ci\_sda, and i2ci\_sccb lines in system test mode are read-only bits.

---

In system test mode (I2Ci.I2C\_SYSTEST[15] ST\_EN set to 1), the I2Ci.I2C\_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C\_STAT[5:0] status bits to 0. The I2Ci.I2C\_STAT[5:0] status bits can be cleared to 0 only by writing 1 in the corresponding bits.

#### 18.4.10 Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I<sup>2</sup>C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I<sup>2</sup>C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C\_CON[10] MST and I2Ci.I2C\_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C\_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C\_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C\_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I<sup>2</sup>C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C\_CON[10] MST to 1 and by clearing the I2Ci.I2C\_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C\_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C\_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C\_DATA register.

---

**Note:** In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C\_BUF[13:8] RTRSH and I2Ci.I2C\_BUF[5:0]XTRSH fields to 0x0.

---

#### 18.4.11 Power Chip Communication Operations

The master transmitter HS I<sup>2</sup>C controller I2C4 inside the voltage controller of the PRM module is used to send configuration commands from the LH to external power chip(s).

For voltage control operations, the LH must set the slave address of the first power chip in the PRCM.PRM\_VC\_SMPS\_SA[6:0] SA0 field, and the slave address of the second power chip (if necessary) in the PRCM.PRM\_VC\_SMPS\_SA[22:16] SA1 field.

The LH must also configure the specific registers in the voltage controller of the PRM module, for the voltage control and power-sequencing functions.

A high-priority bypass mode is available to allow the LH to configure the external power chip(s) through the I<sup>2</sup>C bus. To write an 8-bit data to the configuration registers of an external power chip, the LH must set the 7-bit external power chip slave address in the PRCM.PRM\_VC\_BYPASS\_VAL[6:0] SLAVEADDR field, the configuration register address in the PRCM.PRM\_VC\_BYPASS\_VAL[15:8] REGADDR field, and the 8-bit data in the PRCM.PRM\_BYPASS\_VAL[23:16] register.

For details about voltage control, see [Chapter 4, Power, Reset, and Clock Management](#).

## 18.5 High-Speed I<sup>2</sup>C Controller Basic Programming Model

### 18.5.1 Multimaster HS I<sup>2</sup>C Controller Basic Programming Model in I<sup>2</sup>C Mode

This section describes the programming model of the multimaster HS I<sup>2</sup>C controllers configured in I<sup>2</sup>C mode.

#### 18.5.1.1 Main Program

##### 18.5.1.1.1 Configure the Module Before Enabling the I<sup>2</sup>C Controller

Before enabling the I<sup>2</sup>C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 18.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci\_INTERNAL\_CLK) by programming the corresponding value in the I2Ci.I2C\_PSC[3:0] PSC field. This value depends on the frequency of the functional clock (I2Ci\_FCLK). Because this frequency is 96MHz, the I2Ci.I2C\_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C\_SCLL[7:0] SCLL and I2Ci.I2C\_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps or 400K bps. These values depend on the internal sampling clock frequency (see [Table 18-12](#)).
4. (Optional) Program the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLH[15:8] HSSCLH fields to obtain a bit rate of 400K bps or 3.4M bps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 18-12](#)).
5. (Optional) If a bit rate of 3.4M bps is used and the bus line capacitance exceeds 45 pF, program the CONTROL.CONTROL\_DEVCONF1[12] I2C1HSMASMASTER bit for I2C1, the CONTROL.CONTROL\_DEVCONF1[13] I2C2HSMASMASTER bit for I2C2, or the CONTROL.CONTROL\_DEVCONF1[14] I2C3HSMASMASTER bit for I2C3.
6. Configure the Own Address of the I<sup>2</sup>C controller by storing it in the I2Ci.I2C\_OAO register. Up to four Own Addresses can be programmed in the I2Ci.I2C\_OAi registers (with i = 0, 1, 2, 3) for each I<sup>2</sup>C controller.

---

**Note:** For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C\_CON register.

---

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C\_BUF[5:0]XTRSH field to (TX threshold - 1) and the I2Ci.I2C\_BUF[13:8]RTRSH field to (RX threshold - 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I<sup>2</sup>C controller out of reset by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

##### 18.5.1.1.2 Initialize the I<sup>2</sup>C Controller

To initialize the I<sup>2</sup>C controller, perform the following steps:

1. Configure the I2Ci.I2C\_CON register:
  - For master or slave mode, set the I2Ci.I2C\_CON[10] MST bit (0: slave, 1: master).
  - For transmitter or receiver mode, set the I2Ci.I2C\_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C\_IE register (the I2Ci.I2C\_IE[4] XRDY\_IE bit for the transmit interrupt, the I2Ci.I2C\_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive/transmit data, set to 1 the corresponding bit in the I2Ci.I2C\_BUF register (the I2Ci.I2C\_BUF[15] RDMA\_EN bit for the receive DMA channel, the I2Ci.I2C\_BUF[7] XDMA\_EN bit for the transmit DMA channel).

### 18.5.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C\_SA[9:0] SA field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2Ci.I2C\_CNT[15:0] DCOUNT field.

---

**Note:** For a 10-bit address, set the I2Ci.I2C\_CON[8] XSA bit to 1.

---

### 18.5.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C\_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C\_CON[0] STT and I2Ci.I2C\_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C\_CON[1] STP bit to 1.

### 18.5.1.1.5 Receive Data

Poll the I2Ci.I2C\_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C\_IE[3] RRDY\_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C\_BUF[15] RDMA\_EN bit must be set to 1) to read the receive data in the I2Ci.I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C\_BUF[13:8]RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C\_IE[13] RDR\_IE bit to 1).

---

**Note:** In receive mode only, the I2Ci.I2C\_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I<sup>2</sup>C controller simply holds the serial clock line i2ci\_scl to low to prevent other bytes from being received.

The I2Ci.I2C\_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IE[7] AERR\_IE bit to 1.

---

### 18.5.1.1.6 Transmit Data

Poll the I2Ci.I2C\_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C\_IE[4] XRDY\_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C\_BUF[7] XDMA\_EN bit must be set to 1) to write data to the I2Ci.I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C\_BUF[5:0] XTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C\_IE[14] XDR\_IE bit to 1).

---

**Note:** In transmit mode only, the I2Ci.I2C\_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the I2Ci.I2C\_CNT[15:0] DCOUNT field value is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I<sup>2</sup>C master device still requests data bytes to be read.

The I2Ci.I2C\_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IE[7] AERR\_IE bit to 1.

---

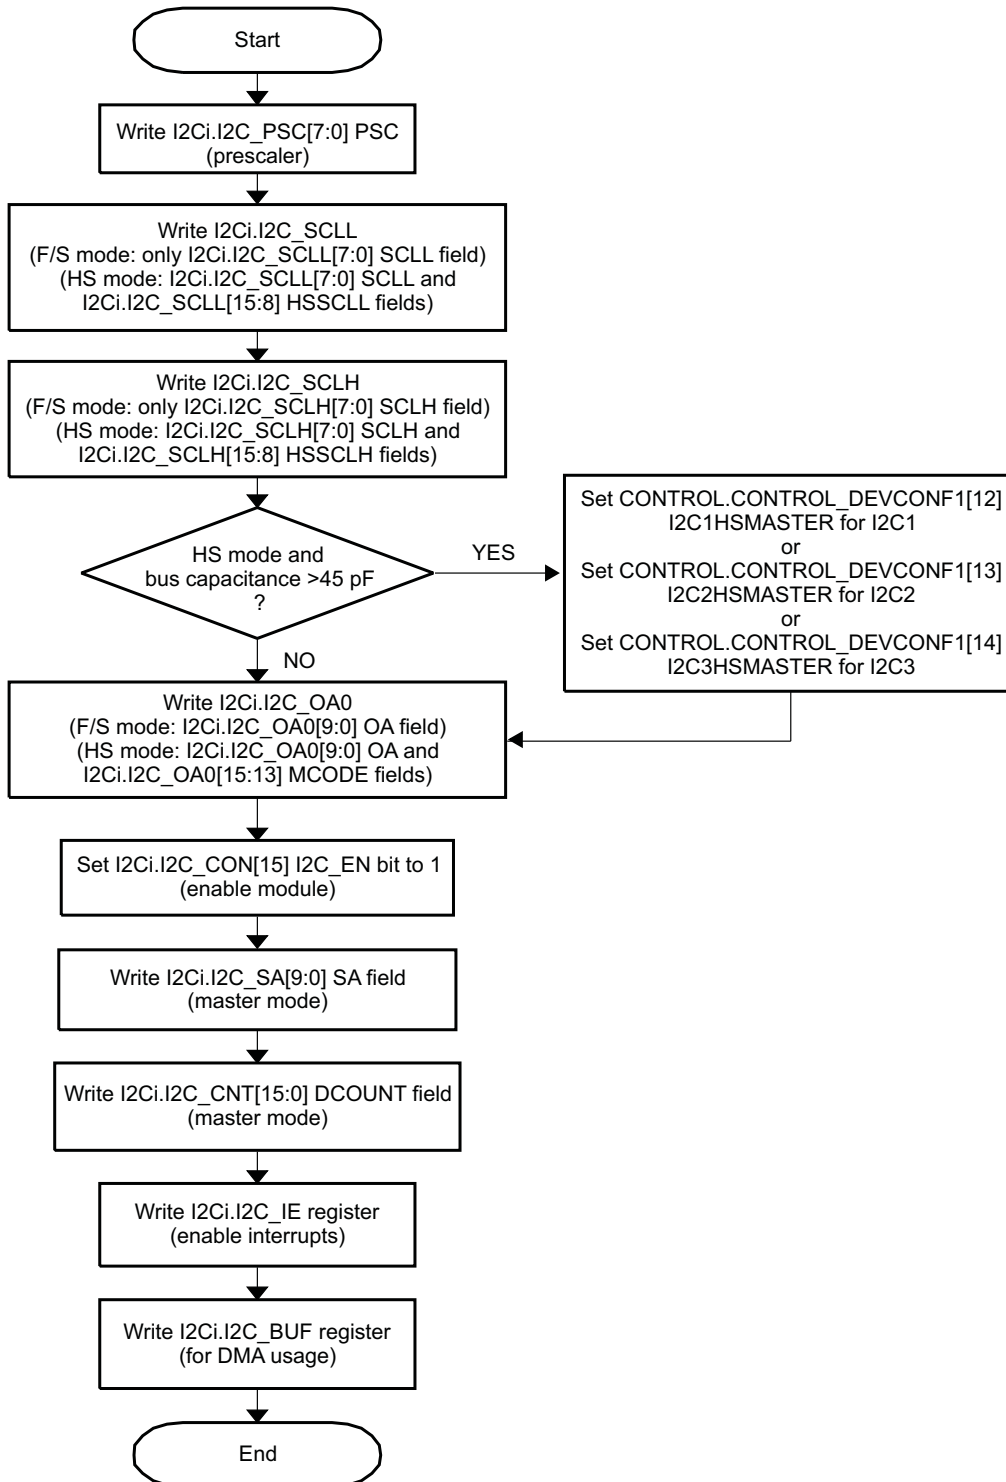

**18.5.1.2 Interrupt Subroutine Sequence**

1. Test for arbitration lost (I2Ci.I2C\_STAT[0] AL status bit) and resolve accordingly.
2. Test for no acknowledgment (I2Ci.I2C\_STAT[1] NACK status bit) and resolve accordingly.
3. Test for register access ready (I2Ci.I2C\_STAT[2] ARDY status bit) and resolve accordingly.
4. Test for receive data ready (I2Ci.I2C\_STAT[3] RRDY status bit) and resolve accordingly.
5. Test for transmit data ready (I2Ci.I2C\_STAT[4] XRDY status bit) and resolve accordingly.
6. Test for general call (I2Ci.I2C\_STAT[5] GC status bit) and resolve accordingly.
7. Test for start (S) condition (I2Ci.I2C\_STAT[6] STC status bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (I2Ci.I2C\_STAT[7] AERR status bit) and resolve accordingly.
9. Test for bus free (I2Ci.I2C\_STAT[8] BF status bit) and resolve accordingly.

### 18.5.1.3 Programming Flow Diagrams

Figure 18-28 through Figure 18-36 are procedure flowcharts for programming the F/S and HS I<sup>2</sup>C modes.

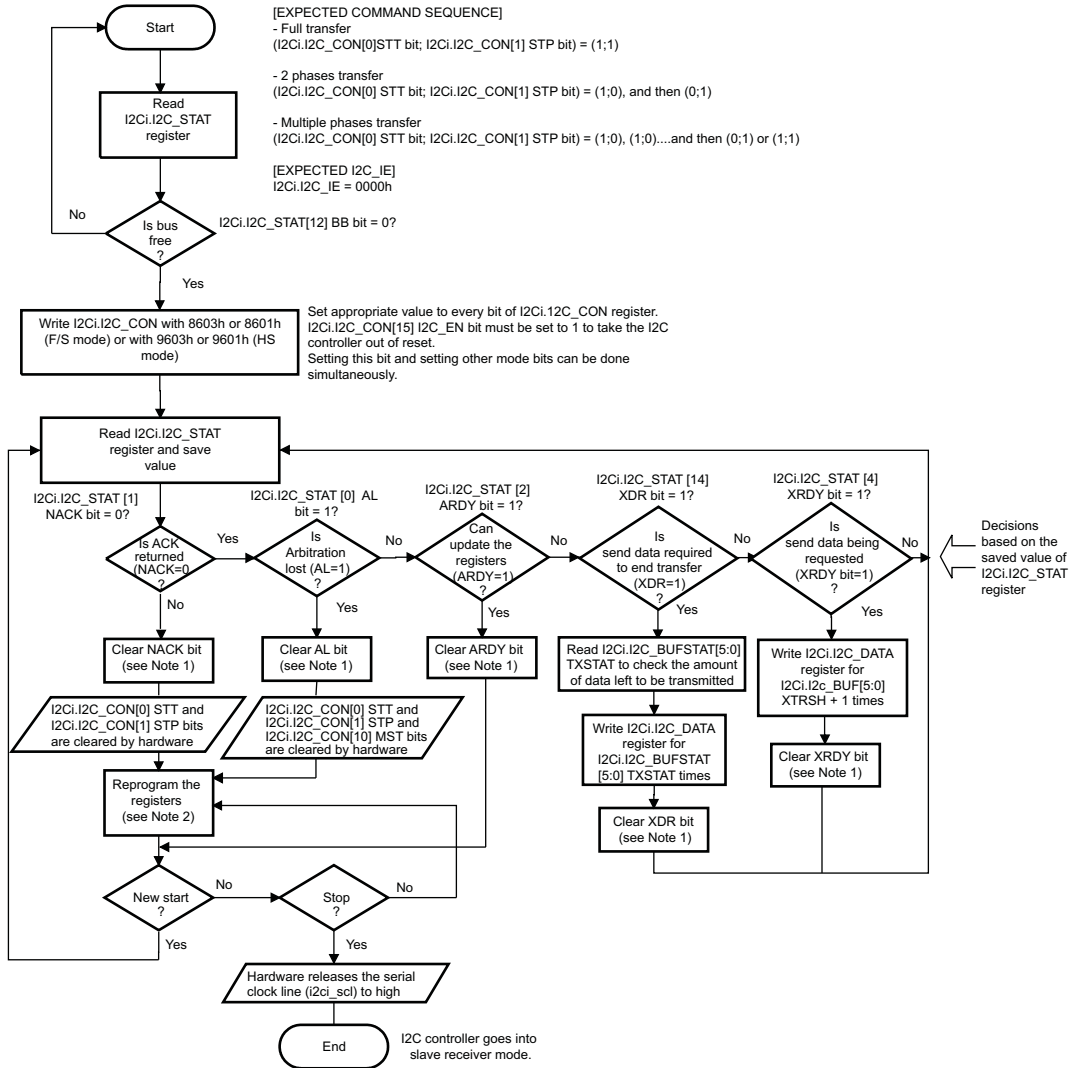

**Figure 18-28. I<sup>2</sup>C Setup Procedure**

- (1) The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C\_STAT register.
- (2) In slave transmitter mode, the amount of data requested by the external master I<sup>2</sup>C device is unknown; thus, the I2Ci.I2C\_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

**Figure 18-36. I<sup>2</sup>C Slave Transmitter/Receiver Mode, Interrupt**

- (1) The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C\_STAT register.
- (2) In slave transmitter mode, the amount of data requested by the external master I<sup>2</sup>C device is unknown; thus, the I2Ci.I2C\_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

## 18.5.2 High-Speed I<sup>2</sup>C Controller Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I<sup>2</sup>C controllers configured in SCCB mode.

### 18.5.2.1 Main Program

#### 18.5.2.1.1 Configure the Module Before Enabling the I<sup>2</sup>C Controller

Before enabling the I<sup>2</sup>C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 18.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci\_INTERNAL\_CLK) by programming the corresponding value in the I2Ci.I2C\_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci\_FCLK). Because this frequency is 96MHz, the I2Ci.I2C\_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C\_SCLL[7:0] SCLL and I2Ci.I2C\_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see [Table 18-12](#)).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C\_SA register.

5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C\_OA0 register.
6. Configure the I2Ci.I2C\_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C\_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I<sup>2</sup>C controller out of reset by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

### 18.5.2.1.2 Initialize the I<sup>2</sup>C Controller

To initialize the I<sup>2</sup>C controller, perform the following steps:

1. Configure the I2Ci.I2C\_CON register:
  - In SCCB mode, only the master mode is supported; set the I2Ci.I2C\_CON[10] MST bit to 1.
  - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C\_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C\_IE register (the I2Ci.I2C\_IE[4] XRDY\_IE bit for the transmit interrupt, the I2Ci.I2C\_IE[3] RRDY bit for the receive interrupt).

### 18.5.2.1.3 Initiate a Transfer

Poll the I2Ci.I2C\_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C\_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C\_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C\_CON[1] STP bit is not used.

### 18.5.2.1.4 Receive Data

Poll the I2Ci.I2C\_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C\_IE[3] RRDY\_IE bit must be set to 1) to read the receive data in the I2Ci.I2C\_DATA register.

---

**Note:** In SCCB mode, the I2Ci.I2C\_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

---

### 18.5.2.1.5 Transmit Data

Poll the I2Ci.I2C\_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C\_IE[4] XRDY\_IE bit must be set to 1) to write the data to the I2Ci.I2C\_DATA register.

---

**Note:** In SCCB mode, the I2Ci.I2C\_BUF[5:0] XTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

---

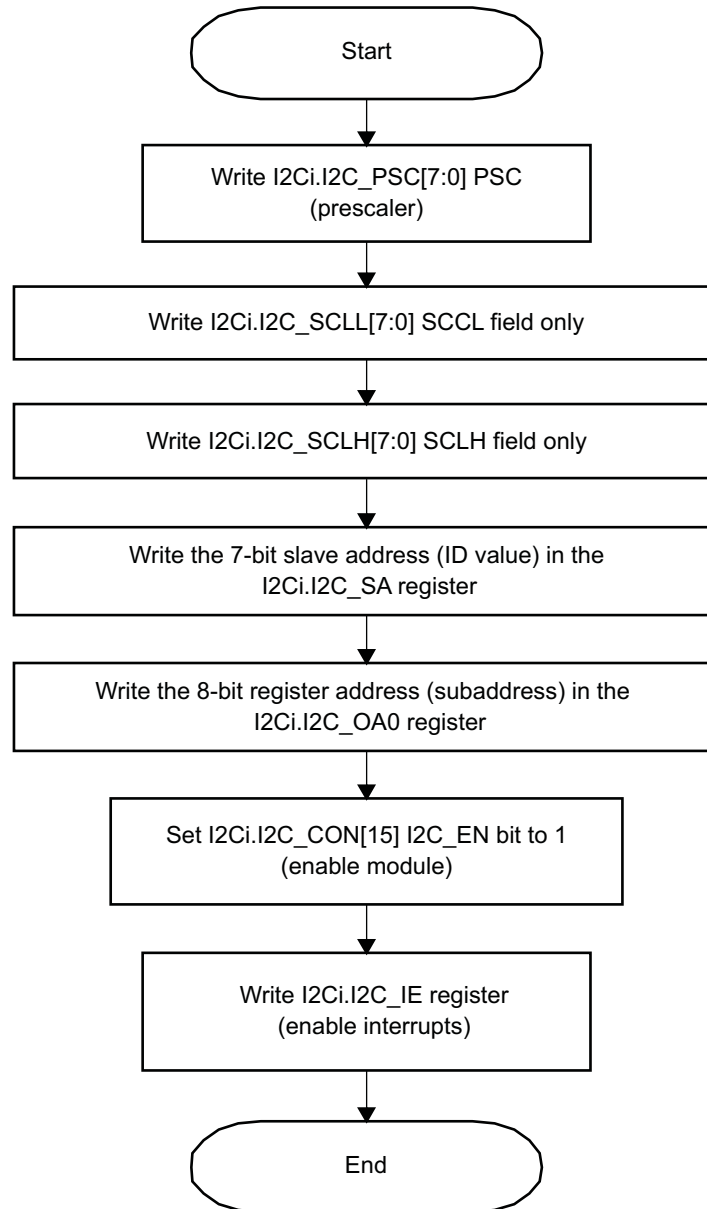

## 18.5.2.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C\_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C\_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C\_STAT[4] XRDY status bit) and resolve accordingly.

### 18.5.2.3 Programming Flow Diagrams

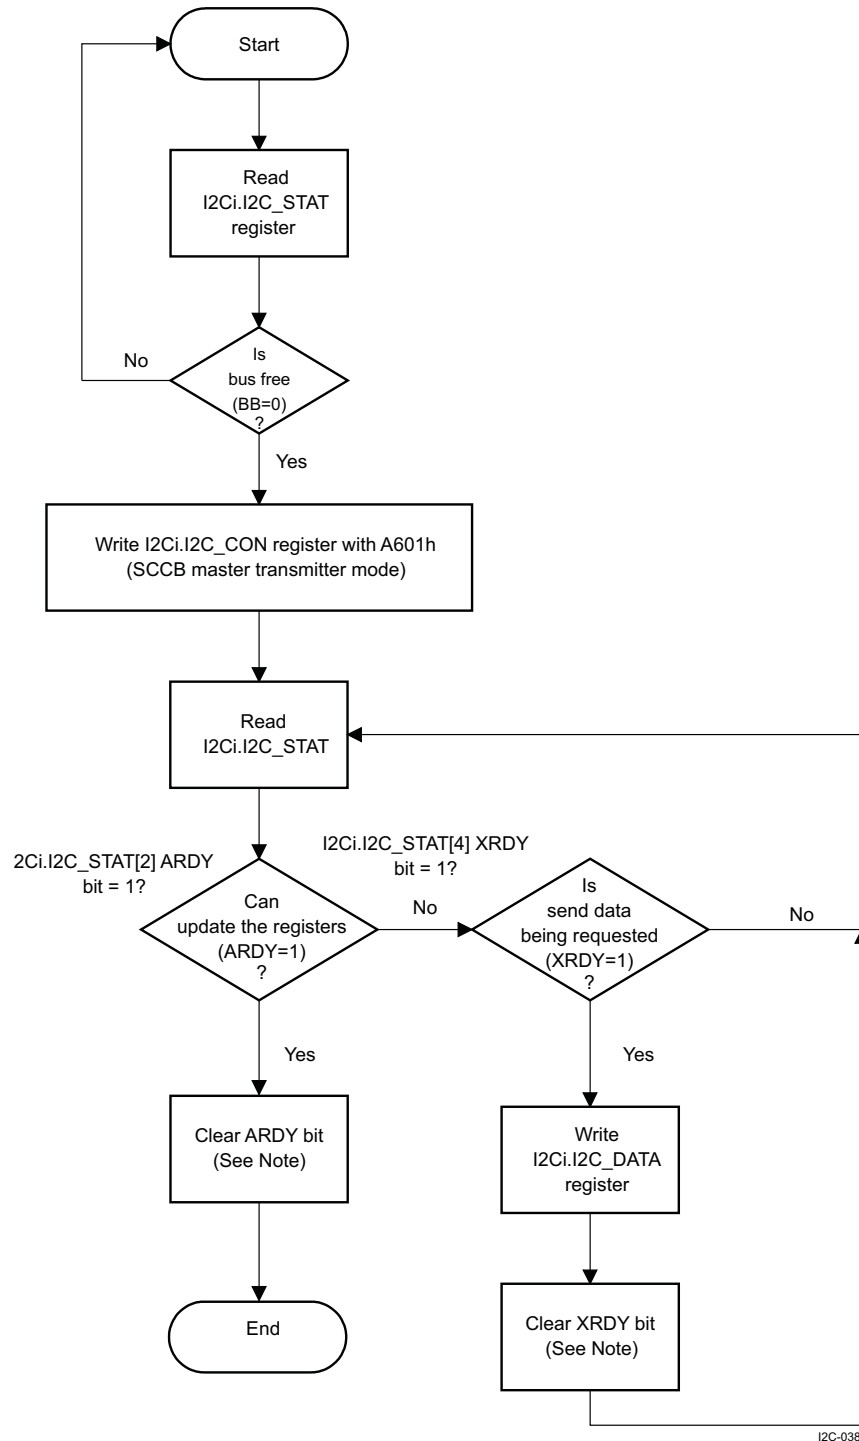

Figure 18-37 through Figure 18-41 are procedure flowcharts for programming the SCCB mode.

**Figure 18-37. SCCB Setup Procedure**

I2C-037

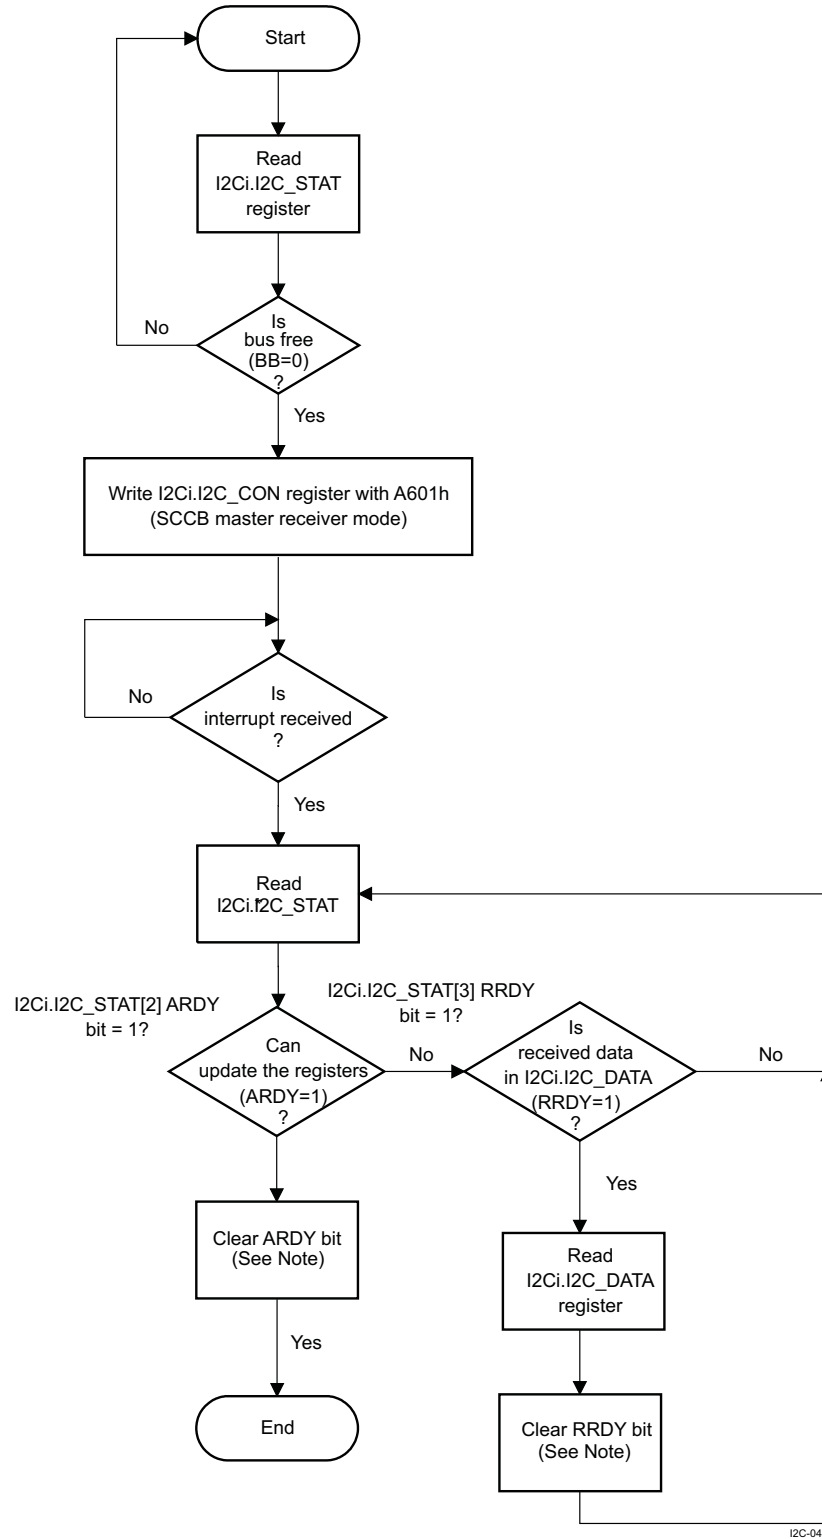

**Figure 18-39. SCCB Master Receiver Mode, Polling**

**Note:** The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C\_STAT register.

Figure 18-40. SCCB Master Transmitter Mode, Interrupt

**Note:** The XRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C\_STAT register.

**Figure 18-41. SCCB Master Receiver Mode, Interrupt**

**Note:** The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C\_STAT register.

### **18.5.3 Master Transmitter HS I<sup>2</sup>C Controller I2C4 Basic Programming Model for Communication With Power Chips**

This section describes the programming model of the master transmitter HS I<sup>2</sup>C controller I2C4 for communication with one or more power chips. The HS I<sup>2</sup>C controller I2C4 allows the two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I<sup>2</sup>C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

#### **18.5.3.1 Configure the Voltage Controller Registers**

To use the voltage control function, the LH must configure the following registers in the voltage controller of the PRCM module:

- The voltage configuration register address for each VDD channel in the PRCM.PRM\_VC\_SMPS\_RA register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM\_VC\_SMPS\_CMD\_RA register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the PRCM.PRM\_VC\_CMD\_VAL\_0 register for the first VDD channel and the PRCM.PRM\_VC\_CMD\_VAL\_1 register for the second VDD channel
- The VDD channels configuration selection in the PRCM.PRM\_VC\_CH\_CONF register

For details about voltage controller register configuration, see [Chapter 4, Power, Reset, and Clock Management](#).

#### **18.5.3.2 Configure the Master Transmitter HS I<sup>2</sup>C Controller I2C4**

At power-on reset, the I2C4 is in HS mode (PRCM.PRM\_VC\_I2C\_CFG[3] HSEN bit). In HS mode, the LH must configure the master code value for the preamble I<sup>2</sup>C high-speed transmission by configuring the PRCM.PRM\_VC\_I2C\_CFG[2:0] MCODE field. If the external power chips do not support the I<sup>2</sup>C HS mode, the HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM\_VC\_I2C\_CFG[3] HSEN bit to 0.

By default, the repeated start operation is enabled (PRCM.PRM\_VC\_I2C\_CFG[4] SREN bit set to 1 at power-on reset). In F/S mode, the repeated start operation can be disabled by clearing the PRCM.PRM\_VC\_I2C\_CFG[4] SREN bit to 0.

#### **18.5.3.3 Configure the External Power Chip(s)**

The LH can send configuration commands from one bypass input to the external power chip(s), using the same I<sup>2</sup>C interface. To send a configuration command, the LH must process as follows:

- Check whether the transmission of a configuration command is ongoing by polling the PRCM.PRM\_VC\_BYPASS\_VAL[24]VALID bit (1: a transmission is ongoing, 0: a new transmission can start).
- Set the external power chip 7-bit slave address in the PRCM.PRM\_VC\_BYPASS\_VAL[6:0] SLAVEADDR field, set the configuration register address of the external power chip in the PRCM.PRM\_VC\_BYPASS\_VAL[15:8] REGADDR field, and set the data to be written to the external power chip configuration register in the PRCM.PRM\_VC\_BYPASS\_VAL[23:16] DATA field.
- Set the PRCM.PRM\_VC\_BYPASS\_VAL[24]VALID bit to 1 to send the configuration command to the external power chip.

## 18.6 High-Speed Multimaster I<sup>2</sup>C Use Cases and Tips

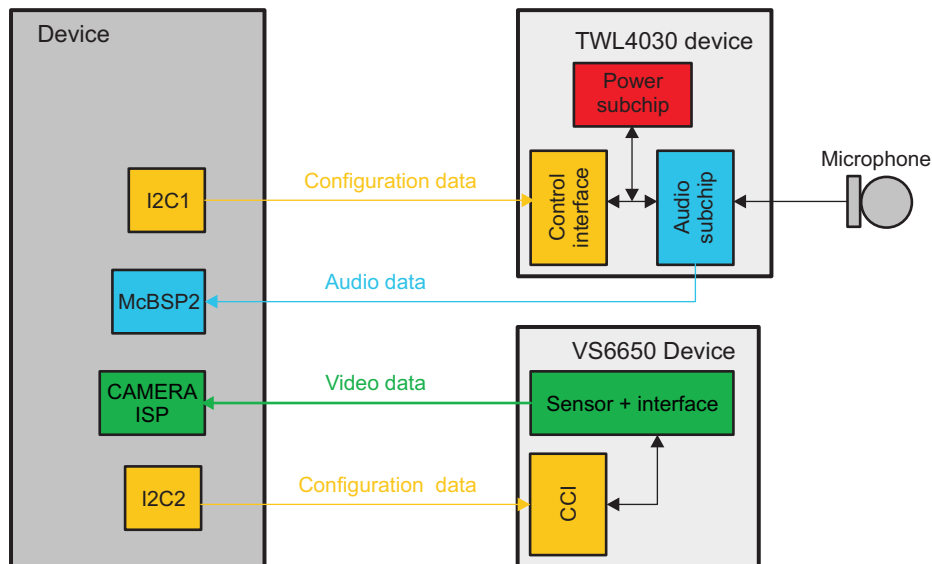

### 18.6.1 Camcorder Use Case: How to Configure the I<sup>2</sup>C Modules When Connecting TWL4030 Companion chip and VS6650 Digital Camera Device

#### 18.6.1.1 Overview

In a whole Camcorder use case, the TWL4030 companion chip and the VS6650 digital camera device are configured by the I<sup>2</sup>C modules inside the OMAP34xx device.

The I2C1 module configures the TWL4030 companion chip, and the I2C3 module configures the VS6650 digital camera device.

**Figure 18-42. Overview**

i2e-042

For the Camcorder use case, the configuration of the I<sup>2</sup>C modules inside the OMAP34xx device is the following:

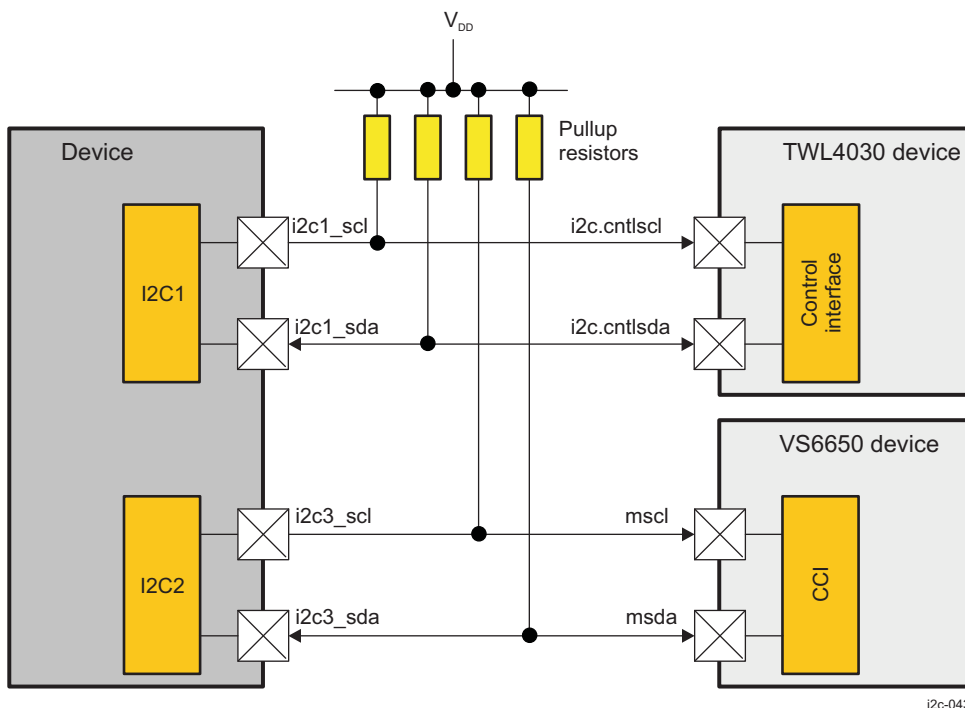

- Master mode: the I<sup>2</sup>C clocks are generated by the I<sup>2</sup>C modules inside the OMAP34xx device.
- Transmit mode: the I<sup>2</sup>C modules write data into the TWL4030 companion chip and the VS6650 digital camera device.
- No start-byte generation.
- Fast/standard (F/S) mode at 100 kbps.
- 7-bit addressing mode to address the TWL4030 companion chip and the VS6650 digital camera device registers.
- Polling method to access the TWL4030 companion chip and the VS6650 digital camera device registers.

#### 18.6.1.2 Environment

In this use case, the control interface of the TWL4030 companion chip is connected to the I2C1 module, while the communication control interface (CCI) of the VS6650 digital camera device is connected to the I2C3 module.

Figure 18-43. Environment

18.6.1.2.1 Data Transfer Formats

The data transfer format for configuring the TWL4030 companion chip and the VS6650 digital camera device is shown as follows:

Figure 18-44. Data Transfer Format

(a) Writing into an external I<sup>2</sup>C device, 7-bit addressing mode

(b) I2C1 Module writing into the TWL4030 companion chip

(c) I2C3 Module writing into the VS6650 digital camera device

To configure a TWL4030 companion chip register, two data bytes must be transmitted by the I2C1 module: the register address (1 byte), and the register value (1 byte).

To configure a VS6650 digital camera device register, three data bytes must be transmitted by the I2C3 module: the index most-significant byte (1 byte), the index less-significant byte (1 byte), and the register value (1 byte).

### 18.6.1.3 Programming Flow

#### 18.6.1.3.1 Initial Configuration

The initialization of the I2Ci module (where i = 1, 3) is done in four parts:

1. I2Ci module interface and functional clocks enabling.
2. I2Ci module clock generation configuration.
3. I2Ci module mode configuration.
4. I2Ci module slave address configuration.
5. I2Ci module enabling.

See [Figure 18-45](#) for the corresponding programming flowchart.

##### 18.6.1.3.1.1 I2Ci Module Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the I2Ci module, the following steps must be done:

1. Enable the interface clock for the I2Ci module (set the PRCM.CM\_ICLKEN1\_CORE[15] EN\_I2C1 bit to 1 for the I2C1 module and the PRCM.CM\_ICLKEN1\_CORE[17] EN\_I2C3 bit to 1 for the I2C3 module).
2. Enable the functional clock for the I2Ci module (set the PRCM.CM\_FCLKEN1\_CORE[15] EN\_I2C1 bit to 1 for the I2C1 module and the PRCM.CM\_FCLKEN1\_CORE[17] EN\_I2C3 bit to 1 for the I2C3 module).

[Table 18-14](#) shows the registers to be configured to initialize the I2C1 and I2C3 modules

**Table 18-14. Registers Print for the I2Ci Module Initialization**

Register	Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x0002 8000	I2C1 and I2C3 interface clocks enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x0002 8000	I2C1 and I2C3 functional clocks enabled

##### 18.6.1.3.1.2 I2Ci Module Clock Generation Configuration

To configure the clock generation of the I2Ci modules, perform the following steps:

1. Configure the I2Ci.I2C\_PSC[3:0] PSC field to 0x17 (23).
2. Configure the I2Ci.I2C\_SCLL[7:0] SCLL field to 0x0D (13).
3. Configure the I2Ci.I2C\_SCLH[7:0] SCLH field to 0x0F (15).

By programming these values, the I<sup>2</sup>C clock rate is configured to 100 kbps for the I2Ci modules.

[Table 18-15](#) shows all the registers to be configured for the I2Ci module clock generation configuration.

**Table 18-15. Registers Print for the I2Ci Module Clock Generation Configuration**

Register	Address	Value	Value Description
I2C1.I2C_PSC	0x4807 0030	0x0017	PSC[3:0] field set to 0x17 for the I2C1 module
I2C1.I2C_SCLL	0x4807 0034	0x000D	SCLL[7:0] field set to 0x0D for the I2C1 module
I2C1.I2C_SCLH	0x4807 0038	0x000F	SCLH[7:0] field set to 0x0F for the I2C1 module

**Table 18-15. Registers Print for the I2Ci Module Clock Generation Configuration (continued)**

Register	Address	Value	Value Description
I2C3.I2C_PSC	0x4806 0030	0x0017	PSC[3:0] field set to 0x17 for the I2C3 module
I2C3.I2C_SCLL	0x4806 0034	0x000D	SCLL[7:0] field set to 0x0D for the I2C3 module
I2C3.I2C_SCLH	0x4806 0038	0x000F	SCLH[7:0] field set to 0x0F for the I2C3 module

#### 18.6.1.3.1.3 I2Ci Module Mode Configuration

To configure the I2Ci modules in F/S (Fast/Standard) mode, set the I2Ci.I2C\_CON[13:12] OPMODE field to 0x0.

**Table 18-16. Registers Print for the I2Ci Slave Address Configuration**

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x0000	OPMODE[13:12] configured to 0x0 for I2C1 (Fast/Standard mode)
I2C3.I2C_CON	0x4806 0024	0x0000	OPMODE[13:12] configured to 0x0 for I2C3 (Fast/Standard mode)

#### 18.6.1.3.1.4 I2Ci Module Slave Address Configuration

To configure the slave address of the I2Ci modules, the following steps must be done:

1. Enable the 7-bit addressing mode by clearing the I2Ci.I2C\_CON[8] XSA bit to 0 because the I<sup>2</sup>C addresses of the TWL4030 companion chip and the VS6650 digital camera device are 7-bit wide.
2. Configure the I2C1.I2C\_SA[9:0] SA field to 0x48, 0x49, 0x4A or 0x4B, so that the I2C1 module can access the TWL4030 companion chip registers. The slave address configured into the I2C1.I2C\_SA[9:0] SA field depends on the TWL4030 companion chip register.
3. Configure the I2C3.I2C\_SA[9:0] SA field to 0x10, so that the I2C3 module can access the VS6650 digital camera device registers. For more information, see the ST VS6650 datasheet.

Table 18-17 shows all the registers to be configured for the I2Ci slave address configuration.

**Table 18-17. Registers Print for the I2Ci Slave Address Configuration**

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x0000	XSA bit is cleared to 0 for the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x0000	XSA bit is cleared to 0 for the I2C3 module
I2C1.I2C_SA	0x4807 002C	0x0048, or 0x0049, or 0x004A, or 0x004B	Slave address of the TWL4030 companion sub-chip for the I2C1 module
I2C3.I2C_SA	0x4806 002C	0x0010	Slave address of the VS6650 digital camera device for the I2C3 module

#### 18.6.1.3.1.5 I2Ci Module Enabling

To enable the I2Ci modules, set the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

Table 18-24 shows all the registers to be configured for the I2Ci slave address configuration.

**Table 18-18. Registers Print for the I2Ci Module Enabling**

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x8000	I2C1 module enabled
I2C3.I2C_CON	0x4806 0024	0x8000	I2C3 module enabled

### 18.6.1.3.2 Operational Mode

Writing a byte into a TWL4030 companion chip or VS6650 digital camera device register is done in five parts:

1. Transfer configuration.
2. I2Ci bus status checking.
3. Transfer initiation.
4. Data transfer.
5. Transfer completion.

See [Figure 18-46](#) for the I2C1 programming flowchart and [Figure 18-47](#) for the I2C3 programming flowchart.

#### 18.6.1.3.2.1 Transfer Configuration

To configure the transfer for the I2Ci module, perform the following steps:

1. Configure the I2Ci.I2C\_CNT[15:0] DCOUNT field to the number of data bytes to be transmitted: 0x02 to transmit 2 bytes to the TWL4030 companion chip by the I2C1 module, 0x03 to transmit 3 bytes to the VS6650 digital camera device by the I2C3 module.
2. Set the I2Ci.I2C\_CON[10] MST bit to 1 (master mode).
3. Set the I2Ci.I2C\_CON[9] TRX bit to 1 (transmit mode).

[Table 18-19](#) shows all the registers to be configured for the transfer configuration.

**Table 18-19. Registers Print for the Transfer Configuration**

Register	Address	Value	Value Description
I2C1.I2C_CNT	0x4807 0018	0x0002	Set the number of transmitted bytes to 0x02 for the I2C1 module
I2C1.I2C_CON	0x4807 0024	0x8600	MST and TRX bits are set to 1 for the I2C1 module (master transmit mode)
I2C3.I2C_CNT	0x4806 0018	0x0003	Set the number of transmitted bytes to 0x03 for the I2C3 module
I2C3.I2C_CON	0x4806 0024	0x8600	MST and TRX bits are set to 1 for the I2C3 module (master transmit mode)

#### 18.6.1.3.2.2 I2Ci Bus Status Checking

Before initiating a transfer, the status of the I2Ci bus must be checked by polling the I2Ci.I2C\_STAT[12] BB bit. The transfer is initiated only when the I2Ci.I2C\_STAT[12] BB bit is set to 0 by the I2Ci module.

[Table 18-20](#) shows all the registers to be configured for the I2Ci bus status checking.

**Table 18-20. Registers Print for the I2Ci Bus Status Checking**

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0008	0x1000	BB bit is set to 1 when the I2C1 bus is busy

**Table 18-20. Registers Print for the I2Ci Bus Status Checking (continued)**

Register name	Address	Value	Value description
I2C3.I2C_STAT	0x4806 0008	0x1000	BB bit is set to 1 when the I2C3 bus is busy

### 18.6.1.3.2.3 Transfer Initiation

Once the I2Ci bus is free, the transfer can be initiated by setting the I2Ci.I2C\_CON[0] STT bit (start). The I2Ci.I2C\_CON[1] STP bit (stop) can also be set to 1 as soon as the I2Ci.I2C\_CON[0] STT bit is cleared to 0 by the I2Ci module in order to generate a stop condition at the end of the transfer.

Table 18-21 shows all the registers to be configured for the transfer initiation.

**Table 18-21. Registers Print for the Transfer Initiation**

Register name	Address	Value	Value description
I2C1.I2C_CON	0x4807 0024	0x8601	STT bit is set to 1 for the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x8601	STT bit is set to 1 for the I2C3 module
I2C1.I2C_CON	0x4807 0024	0x8602	STP bit is set to 1 for the I2C1 module when the STT bit is cleared by the I2C1 module
I2C3.I2C_CON	0x4806 0024	0x8602	STP bit is set to 1 for the I2C3 module when the STT bit is cleared by the I2C3 module

**Note:** As soon as the I2Ci.I2C\_CON[0] STT bit is set to 1, a start condition is generated on the I2Ci bus, and the I2Ci.I2C\_CON[0] STT bit is automatically cleared to 0 by the I2Ci module.

The I2Ci.I2C\_CON[1] STP bit is automatically cleared to 0 at the end of the transfer, when the stop condition is generated on the I2Ci bus.

### 18.6.1.3.2.4 Data Transfer

After the generation of the start condition on the I2Ci bus, the slave address programmed in the I2Ci.I2C\_SA[9:0] SA field is automatically transmitted on the bus, followed by the R\_Wn bit (set to 0) and an acknowledge bit is transmitted by the external I<sup>2</sup>C device to the I2Ci module.

Each time a data byte is requested to be transmitted, the I2Ci.I2C\_STAT[4] XRDY bit is set to 1 by the I2Ci module. When it occurs, the data byte must be written into the I2Ci.I2C\_DATA register and the I2Ci.I2C\_STAT[4] XRDY bit must be cleared by setting it to 1. A software time-out counter can be implemented to detect when no data request is generated by the hardware.

The number of data bytes requested to be transmitted is configured in the I2Ci.I2C\_CNT[15:0] DCOUNT bit field. This number is set to 0x02 for the I2C1 module and set to 0x03 for the I2C3 module.

**Note:** The transmit FIFO threshold must be configured to 1 by configuring the I2Ci.I2C\_BUF[5:0] XTRSH field to 0x00 (done by default).

Table 18-22 shows all the registers to be configured for the data transfer.

**Table 18-22. Registers Print for the Data Transfer**

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0008	0x0010	The XRDY is set to 1 by the I2C1 module
I2C3.I2C_STAT	0x4806 0008	0x0010	The XRDY is set to 1 by the I2C3 module

### 18.6.1.3.2.5 Transfer Completion

Once all data bytes have been transmitted, the stop condition is generated on the I2Ci bus and the I2Ci.I2C\_STAT[2] ARDY status bit is set to 1 by the hardware.

Table 18-23 shows all the registers to be configured for the transfer completion.

**Table 18-23. Registers Print for the Transfer Completion**

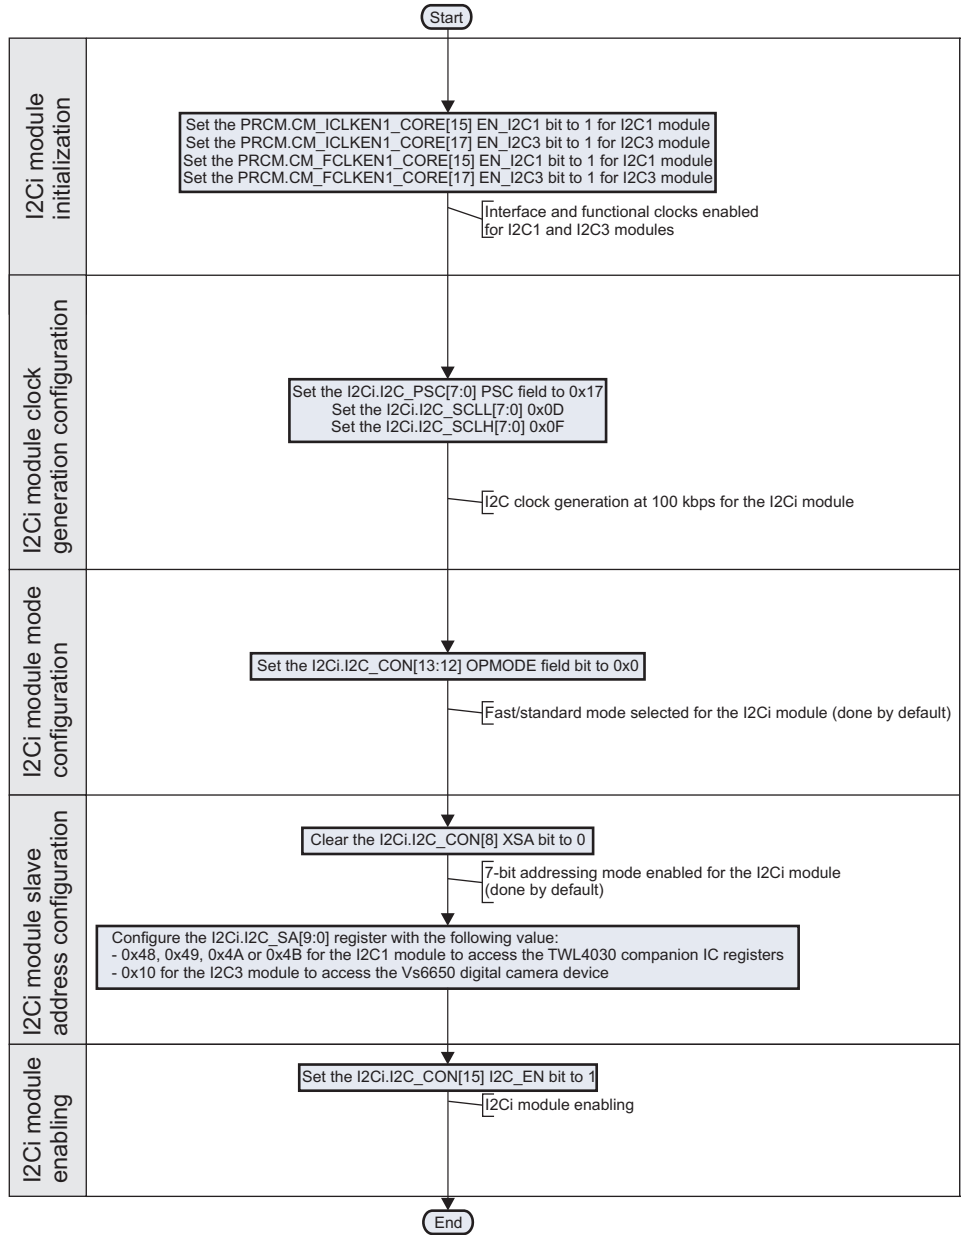

Register name	Address	Value	Value description
I2C1.I2C_STAT	0x4807 0024	0x8604	The ARDY is set to 1 by the I2C1 module (transfer completed)
I2C3.I2C_STAT	0x4806 0024	0x8604	The ARDY is set to 1 by the I2C3 module (transfer completed)

### 18.6.1.3.3 Flowcharts

18.6.1.3.3.1 Initial Configuration Flowchart

Figure 18-45 describes the programming flowchart corresponding to the initial configuration. See Section 18.6.1.3.1 for more information.

Figure 18-45. Initial Configuration Flowchart

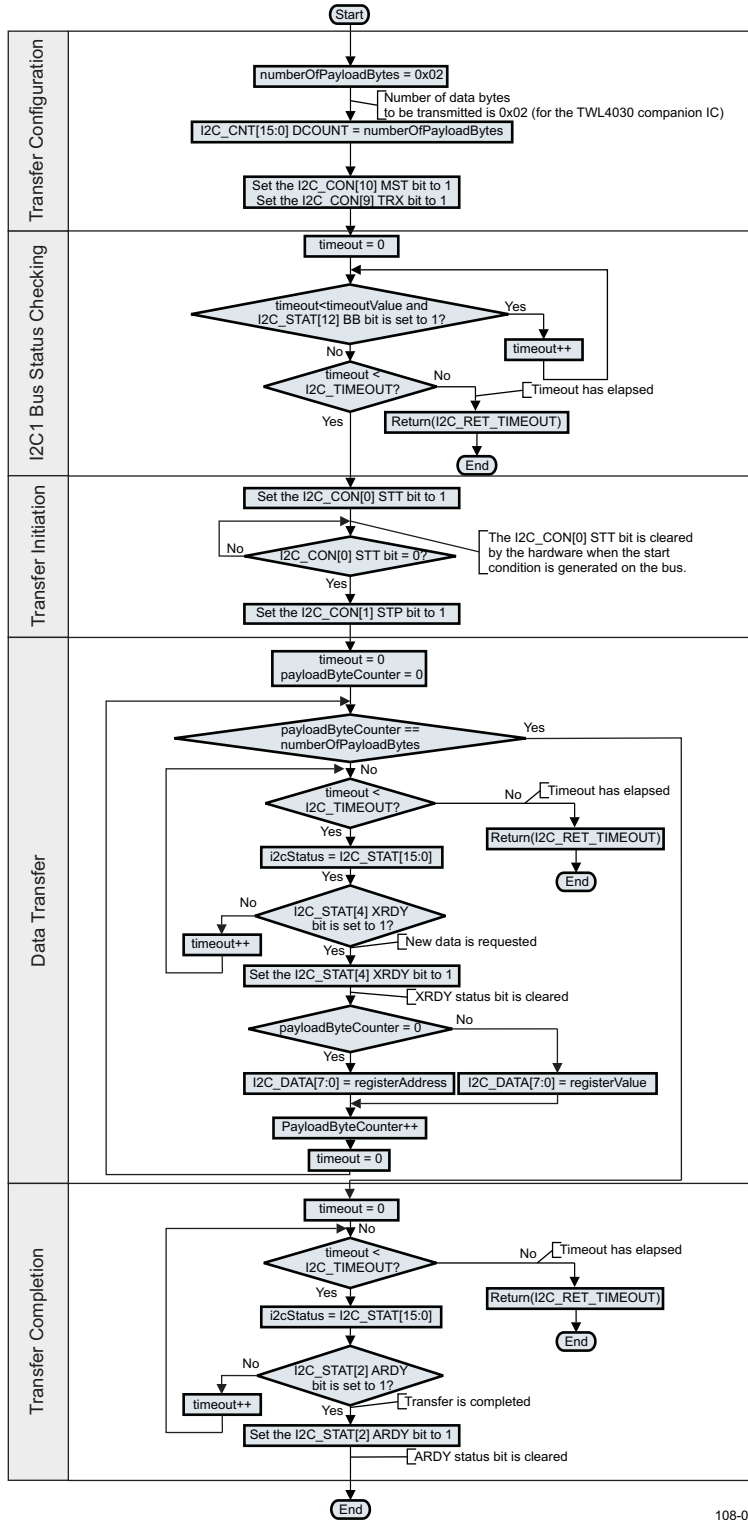

i2c-045

18.6.1.3.3.2 Operational Mode Flowchart

Figure 18-46 describes the programming flowchart for writing a data byte into the TWL4030 companion chip by the I2C1 module. See Section 18.6.1.3.2 for more information. See Table 18-24 for more information about variables and constants used in the programming flowcharts in Figure 18-46 and Figure 18-47.

Figure 18-46. Data Writing into the TWL4030 Companion Chip Register by the I2C1 Module

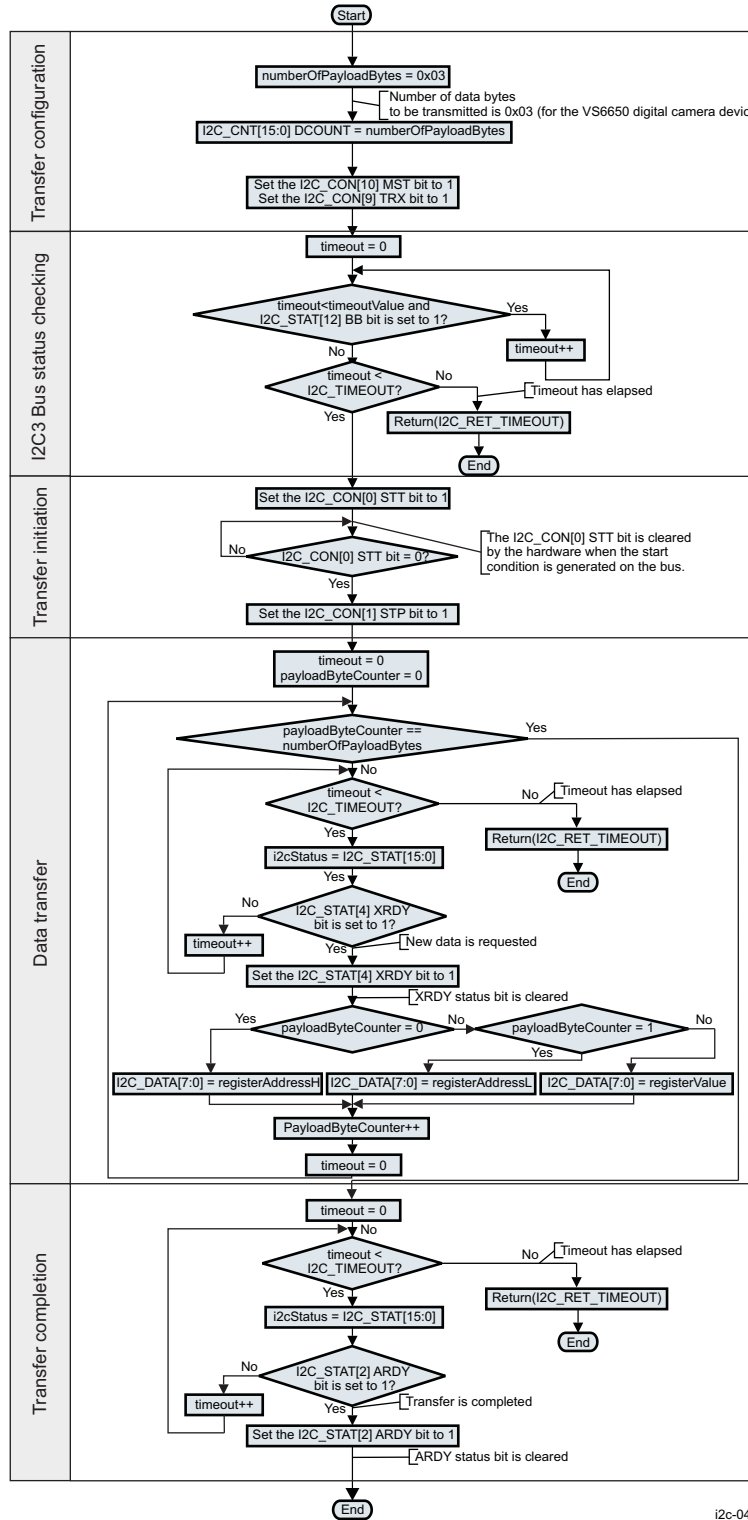

108-046

Figure 18-47 describes the programming flowchart for writing a data byte into the VS6650 digital camera device by the I2C3 module. See Section 18.6.1.3.2 for more information.

Figure 18-47. Data Writing into the VS6650 Digital Camera Device Register by the I2C3 Module

The variables and constants used in the programming flowcharts are described in the [Table 18-24](#).

**Table 18-24. Variables and Constants**

Variable or Constant Name	Type	Tested Value	Description
numberOfPayloadBytes	16-bit unsigned	-	This variable contains the number of data bytes to be transmitted to the external device.
timeout	32-bit unsigned	-	This variable is the timeout counter. When it reaches the I2C_TIMEOUT value, it indicates that the timeout has elapsed.
I2C_TIMEOUT	32-bit unsigned	100 000	This constant contains the maximum value that can be reached by the timeout variable.
payloadByteCounter	16-bit unsigned	-	This variable is a counter that counts the data bytes transmitted to the external device.
registerAddress	8-bit unsigned	-	This variable contains the address of the TWL4030 companion chip register that must be written.
registerAddressM	8-bit unsigned	-	This variable contains the most-significant byte address of the VS6650 digital camera device register that must be written.
registerAddressL	8-bit unsigned	-	This variable contains the less-significant byte address of the VS6650 digital camera device register that must be written.
registerValue	8-bit unsigned	-	This variable contains the value to be written into the external device register

## 18.7 High-Speed I<sup>2</sup>C Controllers Register Manual

### CAUTION

The I2Ci registers are limited to 16 bit and 8 bit data accesses, 32 bit data access is not allowed and can corrupt register content.

**Note:** For details about the master transmitter HS I<sup>2</sup>C controller I2C4, see [Chapter 4, Power, Reset, and Clock Management](#).

[Table 18-25](#) provides the instance summary.

**Table 18-25. Instance Summary**

Module Name	Base Address	Size
I2C1	0x4807 0000	128 bytes
I2C2	0x4807 2000	128 bytes
I2C3	0x4806 0000	128 bytes

### 18.7.1 Multimaster HS I<sup>2</sup>C Controller Register Mapping Summary

[Table 18-26](#) lists the I2Ci registers (where i = 1, 2 and 3).

**Table 18-26. Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address for I2C1	Physical Address for I2C2	Physical Address for I2C3

**Table 18-31. I2C\_STAT**

<b>Address Offset</b>	0x08																															
<b>Physical Address</b>	0x4806 0008				<b>Instance</b>				I2C3				0x4807 0008				I2C1															
	0x4807 2008												I2C2																			
<b>Description</b>	This register provides specific status information about the module, including interrupt status information.																															
<b>Type</b>	RW																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Reserved																Reserved	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL
<b>Bits</b>	<b>Field Name</b>		<b>Description</b>														<b>Type</b>	<b>Reset</b>														
31:16	Reserved		Write 0s for future compatibility. Read returns 0.														RW	0x0000														
15	Reserved		Write 0s for future compatibility. Read returns 0.														RW	0														
14	XDR		Transmit Draining IRQ status Read 0x0: Transmit draining inactive Read 0x1: Transmit draining active Write 0x0: No effect Write 0x1: Clear this bit to 0														RW	0														
13	RDR		Receive Draining IRQ status Read 0x0: Receive draining inactive Read 0x1: Receive draining active Write 0x0: No effect Write 0x1: Clear this bit to 0														RW	0														
12	BB		Bus busy status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Bus is free. Read 0x1: Bus is occupied.														R	0														
11	ROVR		Receive overrun status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Receiver overrun														R	0														
10	XUDF		Transmit underflow status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Transmit underflow														R	0														
9	AAS		Address recognized as slave IRQ status Read 0x0: No action Read 0x1: Address recognized Write 0x0: No effect Write 0x1: Clear this bit to 0.														RW	0														
8	BF		Bus Free IRQ status														RW	0														

Bits	Field Name	Description	Type	Reset
		Read 0x0: No action Read 0x1: Bus free Write 0x0: No effect Write 0x1: Clear this bit to 0.		
7	AERR	Access Error IRQ status Read 0x0: No action Read 0x1: Access error Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
6	STC	Start Condition IRQ status Read 0x0: No action Read 0x1: Start condition detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
5	GC	General Call IRQ status. Set to 1 when general call address detected. Interrupt signaled to MPU subsystem Read 0x0: No general call detected Read 0x1: General call address detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
4	XRDY	Transmit Data Ready IRQ status. Set to 1 in transmit mode when new data is requested for transmission. When this bit is set to 1, an interrupt is signaled to MPU subsystem Read 0x0: No transmit data is requested for transmission Read 0x1: Transmit data is requested for transmission Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
3	RRDY	Receive Data Ready IRQ status. Set to 1 when in receive mode, causing new data to be able to be read. When this bit is set to 1, an interrupt is signaled to MPU subsystem. Read 0x0: No data available Read 0x1: Receive data available Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
2	ARDY	Register Access Ready IRQ status. Setting this bit to 1 indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Read 0x0: Module busy Read 0x1: Access ready Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
1	NACK	No Acknowledgment IRQ status. This bit is set when No Acknowledgment has been received. An interrupt is signaled to MPU subsystem. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1). Read 0x0: Normal operation Read 0x1: No Acknowledge detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0
0	AL	Arbitration Lost IRQ status. This bit is set automatically by the hardware when the I2C controller inside the device loses arbitration in master transmit mode. An interrupt is signaled to MPU subsystem. Read 0x0: Normal operation	RW	0

Bits	Field Name	Description	Type	Reset
		Read 0x1: Arbitration loss detected		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.

## **Multichannel SPI**

---

---

---

This chapter describes the four multichannel serial port interface (McSPI) modules for the OMAP34xx multimedia device.

<b>Topic</b>	<b>Page</b>
<b>19.1 McSPI Overview .....</b>	<b>2759</b>
<b>19.2 McSPI Environment.....</b>	<b>2762</b>
<b>19.3 McSPI Functional Interface .....</b>	<b>2765</b>

<b>19.5 McSPI Functional Description .....</b>	<b>2774</b>
<b>19.6 McSPI Basic Programming Model .....</b>	<b>2795</b>
<b>19.7 McSPI Use Cases and Tips .....</b>	<b>2816</b>
<b>19.8 McSPI Register Manual.....</b>	<b>2822</b>

## 19.1 McSPI Overview

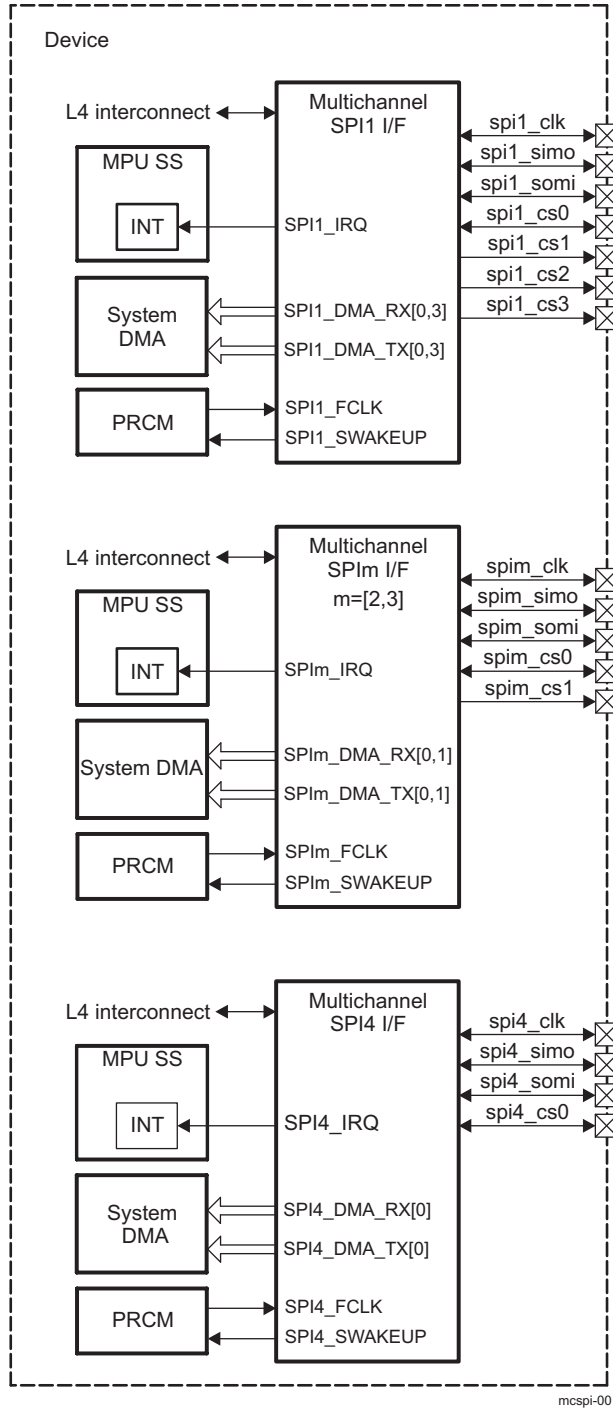

The multichannel serial port interface (McSPI) is a master/slave synchronous serial bus. There are four separate McSPI modules (SPI1, SPI2, SPI3, and SPI4) in the device (see [Figure 19-1](#)). The McSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

---

**Note:** In this chapter,  $m=[1,4]$  represents the module instance and  $x$  represents the channel in signal and register naming. There are four McSPI instances. Each module instance has different channel numbers:

- SPI1: 4 channels (if  $m=1$ ,  $x=4$ )
  - SPI2: 2 channels (if  $m=2$ ,  $x=2$ )
  - SPI3: 2 channels (if  $m=3$ ,  $x=2$ )
  - SPI4: 1 channel (if  $m=4$ ,  $x=1$ )
-

Figure 19-1. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

The McSPI instances include the following main features:

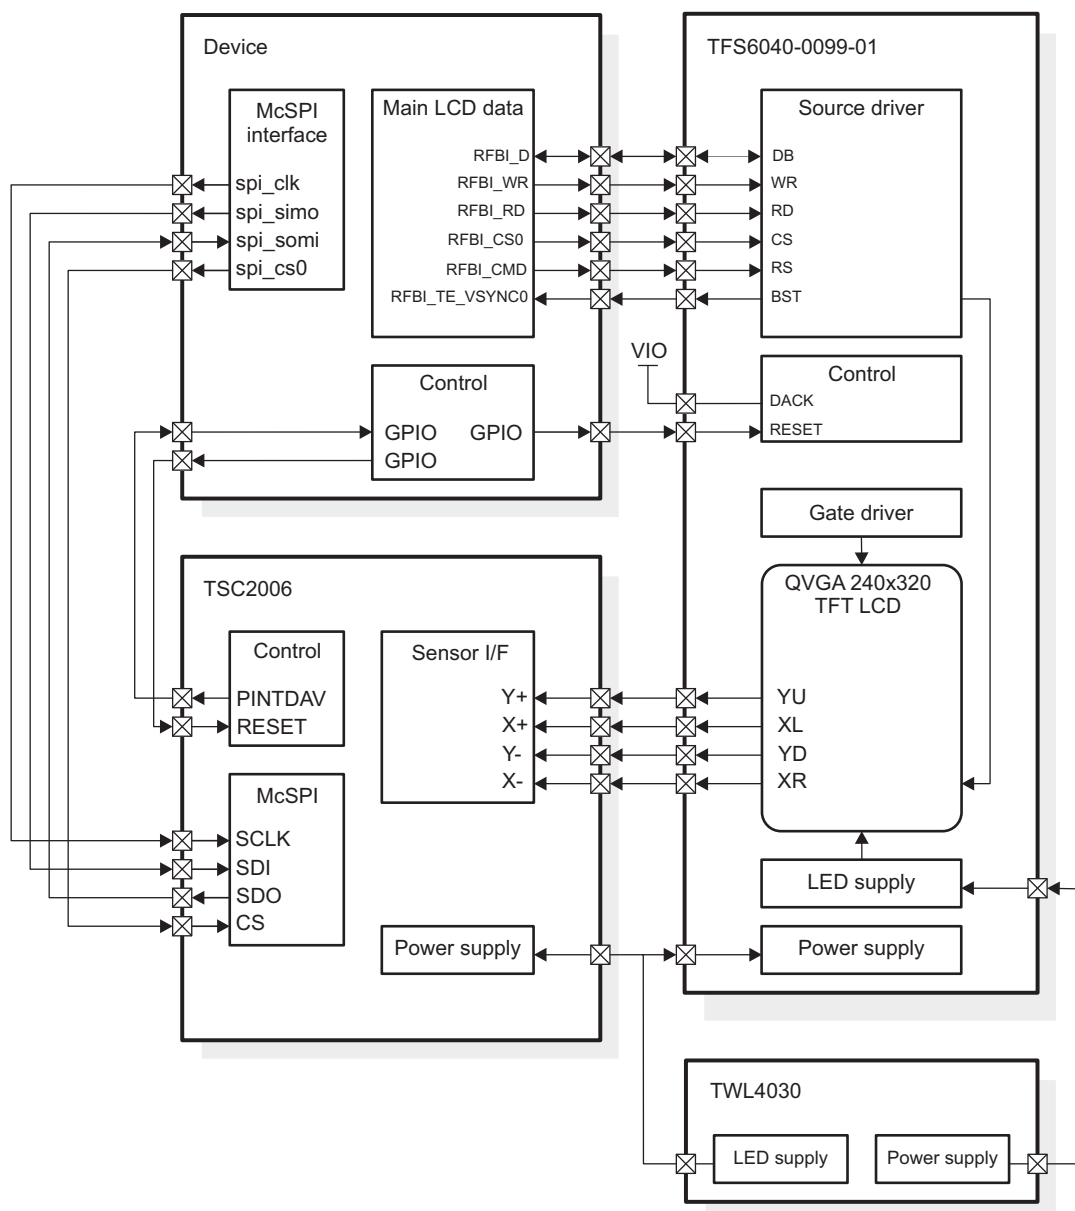

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Up to four master channels or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes

- Flexible I/O port controls per channel
- Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Support start-bit write command
- Support start-bit pause and break sequence
- 64 bytes built-in FIFO available for a single channel
- Force CS mode for continuous transfers

## 19.2 McSPI Environment

Figure 19-2 shows a simplified overview of a typical application system using the McSPI. This example is based on a TFS chipset (TFS6040-0098), including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with the TSC2005 or TSC2006 touch-screen controller, powered by a TWL4030 power-management unit, and driven by the device. The McSPI device interface is set to master mode; the touch-screen McSPI controller interface operates in slave mode.

Figure 19-2. Typical Application Using the McSPI

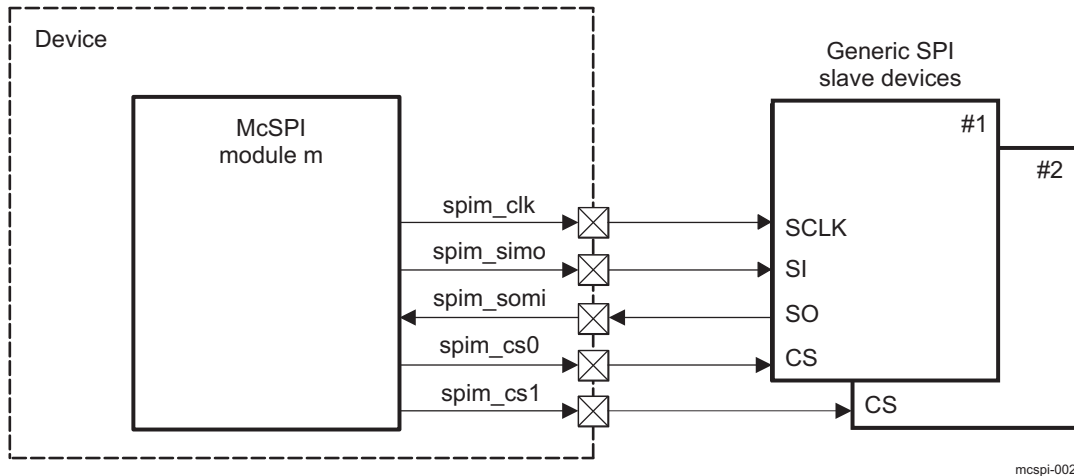

108-034

Figure 19-3 through Figure 19-8 show master mode and slave mode configurations. Each mode can be wired on a single-duplex or full-duplex configuration.

### 19.2.1 SPI Interface in Master Mode

Figure 19-3 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

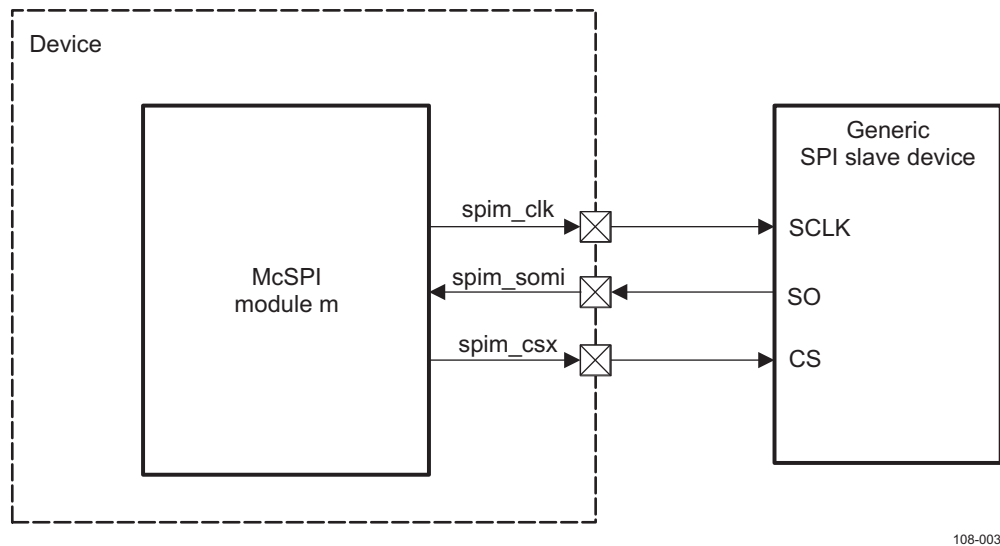

**Figure 19-3. McSPI Master Mode (Full-Duplex)**

**Note:** In this case  $m=[1,3]$ .

Figure 19-4 shows the master single mode, which can also be configured in receive-only mode.

**Figure 19-4. McSPI Master Single Mode (Receive-Only)**

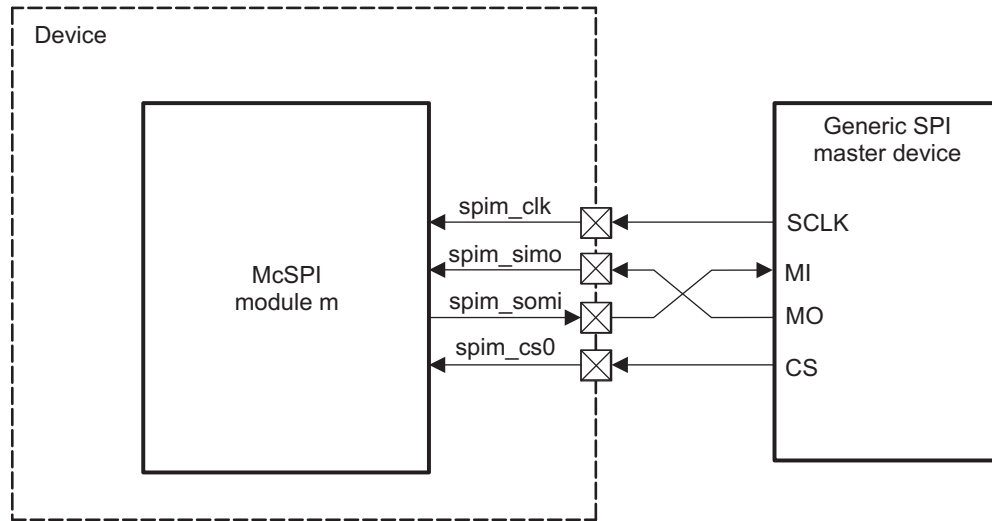

### 19.2.2 SPI Interface in Slave Mode

Figure 19-5 shows a case in slave mode (full-duplex).

**Note:** Only channel 0 can be configured as slave, and only `spin_cs0` can be used as a chip-enable in slave mode.

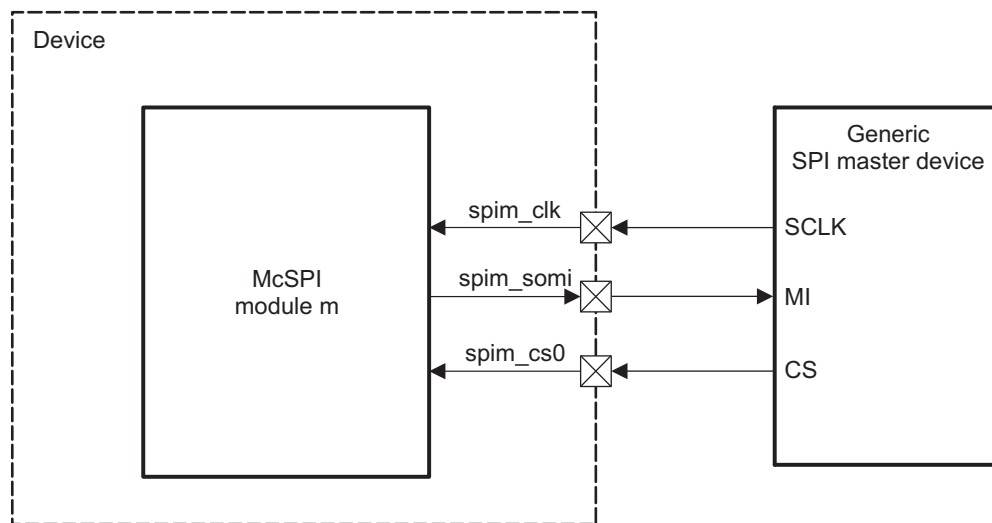

**Figure 19-5. McSPI Slave Mode (Full Duplex)**

108-004

Figure 19-6 shows the slave single mode, which can also be configured in transmit-only mode.

**Figure 19-6. McSPI Slave Single Mode (Transmit Only)**

108-005

## 19.3 McSPI Functional Interface

### 19.3.1 Basic McSPI Pins for Master Mode

Figure 19-7 shows all of the McSPI interface signals in master mode.

**Figure 19-7. McSPI Interface Signals in Master Mode**

Table 19-1 describes the McSPI I/O in master mode.

**Table 19-1. McSPI I/O Description (Master Mode)**

Signal Name	I/O	Description	Reset <sup>(1)</sup>
spim_clk	O	SPIm module serial clock <sup>(2)</sup>	Unknown
spim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	I	SPIm module serial data master input (slave output, master input)	—
spim_csx	O	SPIm module chip-select x output	Low

(1) After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPIm\_MODULCTRL[2] MS bit in the module control register [MCSPIm\_MODULCTRL]).

(2) This output signal is also used as re-timing input.

### 19.3.2 Basic McSPI Pins for Slave Mode

Figure 19-8 shows all of the McSPI interface signals in slave mode.

**Figure 19-8. McSPI Interface Signals in Slave Mode**

Table 19-2 describes the McSPI I/O in slave mode.

**Table 19-2. McSPI I/O Description (Slave Mode)**

Signal Name	I/O	Description	Reset <sup>(1)</sup>
spim_clk	I	SPIm module serial clock	Unknown
spim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	O	SPIm module serial data master input (slave output, master input)	–
spim_cs0	I/O	SPIm module chip-select 0 input	HiZ
spim_cs1/2/3	O	SPIm module chip-select 1/2/3 output	Low

<sup>(1)</sup> After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI\_MODULCTRL[2] MS bit in Module Control Register (MCSPI\_MODULCTRL).)

### 19.3.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (spim\_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length  
McSPI supports any SPI word ranging from 4 bits to 32 bits long (SPIm.MCSPI\_CHxCONF[11:7] WL field).  
SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (spim\_csx, for channel x of instance m)  
The polarity of the SPI enable signals is programmable (SPIm.MCSPI\_CHxCONF[6] EPOL bit). spim\_csx signals can be active high or low.  
The assertion of the spim\_csx signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. spim\_csx can be kept active between words with the SPIm.MCSPI\_CHxCONF[20] FORCE bit.  
Two consecutive words for two different slave devices can go along with active spim\_csx signals with different polarity (see the example in [Section 19.6, McSPI Basic Programming Model](#)).
- Programmable start-bit  
In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPIm.MCSPI\_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI\_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
  - Bit rate  
In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 19-3](#) gives the spim\_clk bit rates obtained for data transfer when programming the clock divider (SPIm.MCSPI\_CHxCONF[5:2] CLKD bit field).

**Table 19-3. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz

**Table 19-3. SPI Master Clock Rates (continued)**

Divider	Clock Rate
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

– Polarity and phase

The polarity (the SPIm.MCSPI\_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPI\_CHxCONF[0] PHA bit) of the SPI serial clock (spim\_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 19-4](#) and [Figure 19-9](#).

**Table 19-4. Phase and Polarity Combinations**

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	spim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	spim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	spim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	spim_clk is active low and sampling occurs on the rising edge.

**Figure 19-9. Phase and Polarity Combinations**

108-009

**19.3.3.1 Transfer Format**

In both master and slave modes, McSPI drives the data lines when spim\_csx is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

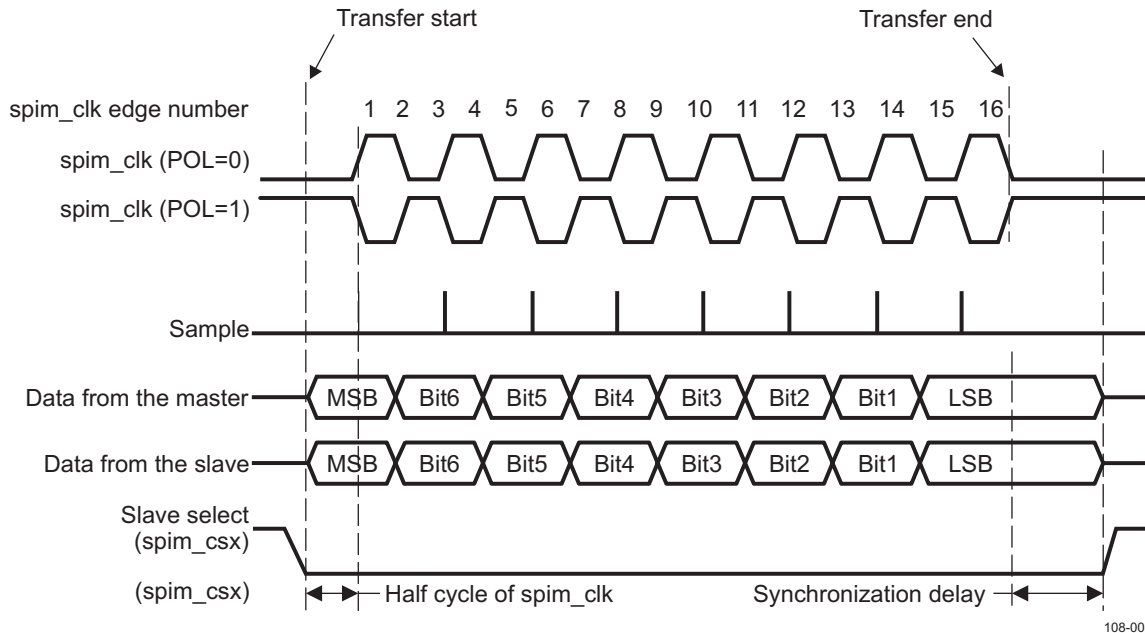

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim\_clk after the spim\_csx assertion.

Therefore, the first edge of the spim\_clk line is used by the master to sample the first data bit sent by

the slave. On the same edge, the first data bit sent by the master is sampled by the slave. On the next `spim_clk` edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line. This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 19-10](#).

**Figure 19-10. Full-Duplex Transfer Format With PHA = 0**

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following `spim_clk` edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the `spim_csx` activation and the first `spim_clk` edge.

The received data bit is shifted into the shift register on the third `spim_clk` edge.

This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

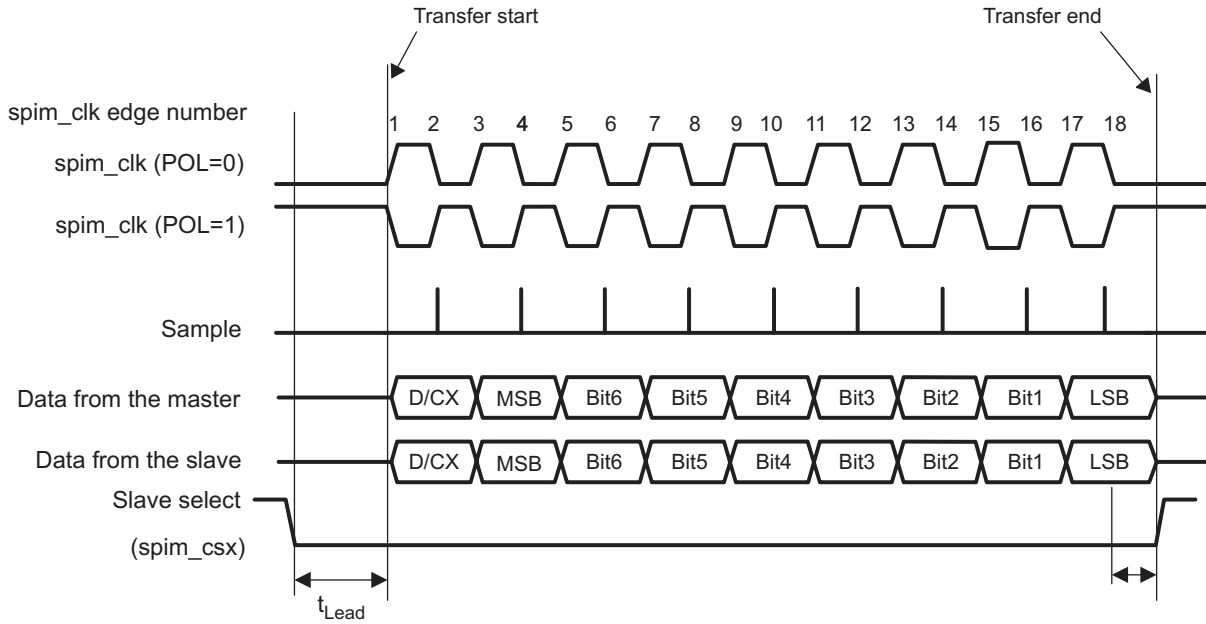

**Note:** The minimum synchronization delay is one cycle of `spim_clk`, if the `spim_clk` frequency equals the `SPI_M_FCLK` (McSPI functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of `spim_clk`, if the `spim_clk` frequency is lower than the `SPI_M_FCLK` frequency in both master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the `SPI_MCSPI_CHXCONF[23]` SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 19-11](#) shows an example of a data transfer with an extra start-bit.

**Figure 19-11. Extended SPI Transfer With a Start-Bit (SBE = 1)**

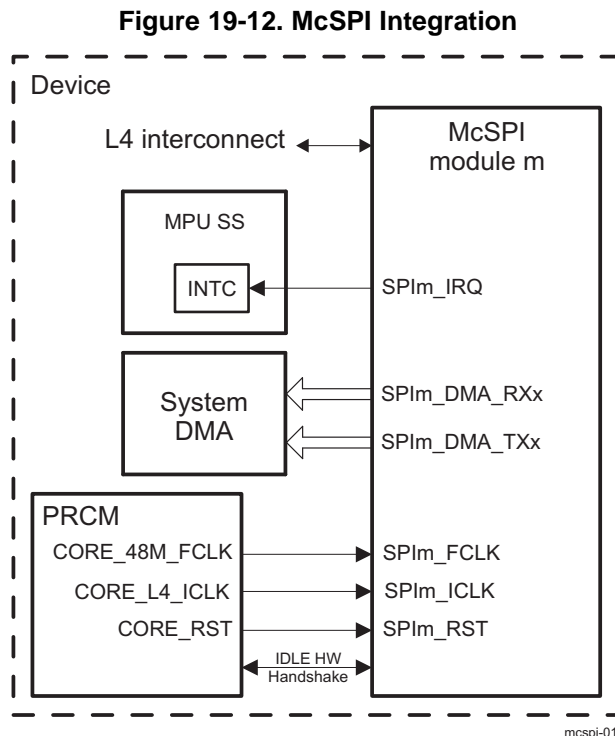

108-010

## 19.4 McSPI Integration

### 19.4.1 McSPI Description

Figure 19-12 highlights the McSPI module integration in the device.

### 19.4.2 Clocking, Reset, and Power-Management Scheme

#### 19.4.2.1 Clocking

Each McSPI module is clocked with an independent functional clock of 48 MHz from the PRCM module (SPIIm\_FCLK with  $m = [1,4]$ ) and with an interface clock, CORE\_L4\_ICLK (L4 interconnect):

- SPIIm\_FCLK is the McSPI module  $m$  functional clock and is used to clock the McSPI internal logic. The source of SPIIm\_FCLK is the PRCM CORE\_48M\_FCLK output clock.
- SPIIm\_ICLK is the McSPI module  $m$  interface clock and is used to synchronize the McSPI L4 port to the L4 interconnect. All accesses from the interconnect are synchronous with SPIIm\_ICLK. The source of SPIIm\_ICLK is the PRCM CORE\_L4\_ICLK output clock.

From a global system power management perspective, when one or both of the McSPI clocks is not required, the McSPI module can be deactivated at the PRCM level in the corresponding registers.

Table 19-5 describes the McSPI module PRCM clock control bits.

**Table 19-5. McSPI Clocks**

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPIIm_FCLK	CORE_48M_FCLK	PRCM.CM_FCLKEN1_CORE.EN_M CSPIIm (with $m=[1,4]$ )	N/A

**Table 19-5. McSPI Clocks (continued)**

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPI <sub>m</sub> _ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE.EN_M CSPI <sub>m</sub> (with m=[1,4])	PRCM.CM_AUTOIDLE1_CORE.AUTO _MCSPIm (with m=[1,4])

**Notes:**

- The PRCM CORE\_48M\_FCLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM CORE\_L4\_ICLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM.CM\_AUTOIDLE1\_CORE bit is used to link/unlink the McSPI module from CORE\_L4\_ICLK-related clock domain transitions.

For more information about source clocks gating and domain transitions, see [Chapter 4, Power, Reset, and Clock Management](#). For more information on power saving management, see [Section 19.5.7](#).

**19.4.2.2 Power Domain**

The McSPI modules belong to the CORE power domain (see [Table 19-6](#)).

**Table 19-6. Power Domain**

Peripherals	Power Domain
McSPI modules	CORE power domain

**19.4.2.3 Hardware Reset**

As part of the CORE power domain, CORE\_RST is issued by the PRCM module (for more information about the CORE power domain implementation and CORE\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#)). The module is reset by hardware when an active-low reset signal is asserted. The hardware reset signal has a global reset effect on the module. All configuration registers and all state-machines are reset in all clock domains (see [Table 19-7](#)).

**Table 19-7. McSPI Hardware Reset**

Peripherals	Name	Comments
McSPI module	CORE_RST	Same as global reset

**19.4.2.4 Software Reset**

The SPI<sub>m</sub>.MCSPI\_SYSCONFIG[1] SOFTRESET bit controls the software reset of the SPI interface. Writing 1 to this bit enables active software reset functionality, which is equivalent to a hardware reset. The bit is automatically reset by hardware.

**Note:** The SPI<sub>m</sub>.MCSPI\_SYSCONFIG register is not sensitive to software reset.

### 19.4.3 Hardware Requests

#### 19.4.3.1 DMA Requests

Each channel includes two DMA requests, one for reception and one for transmission (see [Table 19-8](#)).

**Table 19-8. DMA Requests**

Attributes	DMA Request	Name	Mapping	Comments
<b>SPI1</b>				
	8	SPI1_DMA_TX0	S_DMA_34	Destination is system DMA (sDMA).
		SPI1_DMA_RX0	S_DMA_35	
		SPI1_DMA_TX1	S_DMA_36	
		SPI1_DMA_RX1	S_DMA_37	
		SPI1_DMA_TX2	S_DMA_38	
		SPI1_DMA_RX2	S_DMA_39	
		SPI1_DMA_TX3	S_DMA_40	
		SPI1_DMA_RX3	S_DMA_41	
<b>SPI2</b>				
	4	SPI2_DMA_TX0	S_DMA_42	Destination is sDMA.
		SPI2_DMA_RX0	S_DMA_43	
		SPI2_DMA_TX1	S_DMA_44	
		SPI2_DMA_RX1	S_DMA_45	
<b>SPI3</b>				
	4	SPI3_DMA_TX0	S_DMA_14	Destination is sDMA.
		SPI3_DMA_RX0	S_DMA_15	
		SPI3_DMA_TX1	S_DMA_22	
		SPI3_DMA_RX1	S_DMA_23	
<b>SPI4</b>				
	2	SPI4_DMA_TX0	S_DMA_69	Destination is sDMA.
		SPI4_DMA_RX0	S_DMA_70	

### 19.4.3.2 Interrupt Requests

Each McSPI module handles one interrupt line (see [Table 19-9](#)).

**Table 19-9. Interrupt Requests**

Attributes	Interrupt Request	Name	Mapping	Comments
<b>SPI1</b>	1	SPI1_IRQ	M_IRQ_65	Destination is the microprocessor unit (MPU) interrupt controller.
<b>SPI2</b>	1	SPI2_IRQ	M_IRQ_66	Destination is the MPU interrupt controller.
<b>SPI3</b>	1	SPI3_IRQ	M_IRQ_91	Destination the MPU interrupt controller.
<b>SPI4</b>	1	SPI4_IRQ	M_IRQ_48	Destination is the MPU interrupt controller.

### 19.4.3.3 Wake-Up Requests

[Table 19-10](#) lists the wake-up requests.

**Table 19-10. Wake-Up Requests**

Attributes	Wake Request	Name	Mapping	Comments
<b>SPI1</b>	1	spi1_cs0	SPI1_SWAKEUP	Destination is the PRCM module.
<b>SPI2</b>	1	spi2_cs0	SPI2_SWAKEUP	Destination is the PRCM module.
<b>SPI3</b>	1	spi3_cs0	SPI3_SWAKEUP	Destination is the PRCM module.
<b>SPI4</b>	1	spi4_cs0	SPI4_SWAKEUP	Destination is the PRCM module.

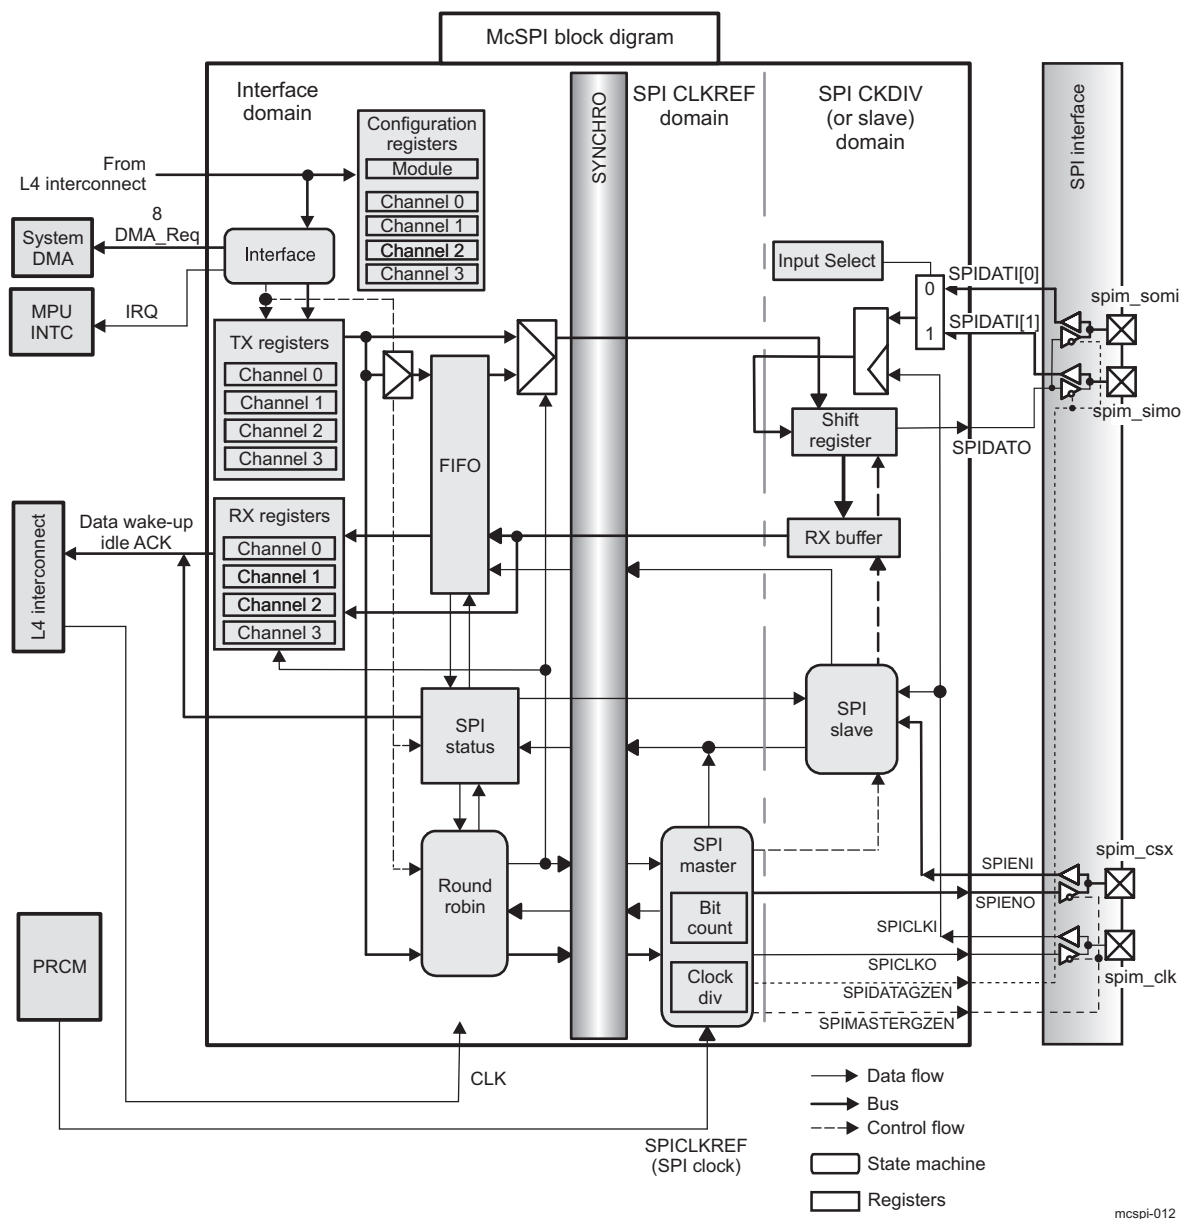

## 19.5 McSPI Functional Description

### 19.5.1 McSPI Block Diagram

Figure 19-13 shows the McSPI module.

Figure 19-13. McSPI Block Diagram

### 19.5.2 Master Mode

#### 19.5.2.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (spim\_simo and spim\_somi) and generates clock (spim\_clk) and control signals (spim\_csx).

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information on interrupts, see [Section 19.5.5.1, Interrupt Events in Master Mode](#)).

### 19.5.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on `spim_simo`) and received (shifted in serially on `spim_somi`) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field).

Channel access to the shift registers for transmission/reception is based on the `MCSPI_TXx` transmitter register state, the `MCSPI_RXx` receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

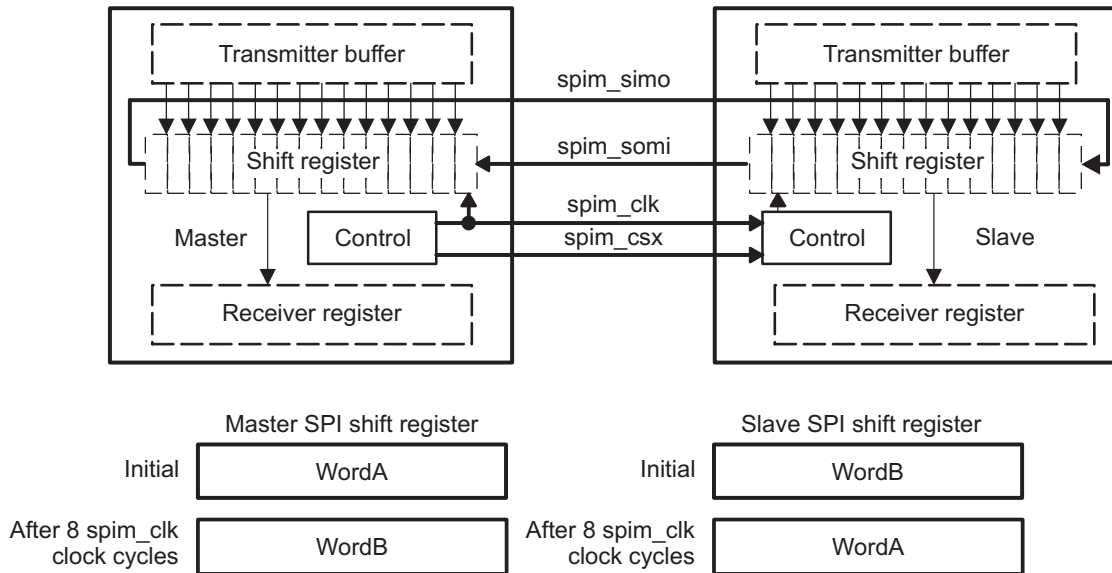

- Rule 1: Only enabled channels (the `SPIm.MCSPI_CHxCTRL[0]` EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its `MCSPI_TXx` transmitter register is not empty (the `SPIm.MCSPI_CHxSTAT[1]` TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the `MCSPI_TXx` register is empty when the shift register is assigned, the `TXx_UNDERFLOW` event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the `SPIm.MCSPI_CHxSTAT[0]` RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the `MCSPI_RXx` register cannot be overwritten. Note that the `SP11.MCSPI_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set to this mode.

When SPI word transfer completes (the `SPIm.MCSPI_CHxSTAT[2]` EOT bit is set), the updated `MCSPI_TXx` register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (`spim_clk`) synchronizes shifting and sampling of the information on the two serial data lines (`spim_simo` and `spim_somi`). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 19-14](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock `spim_clk`, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 19-14. SPI Full-Duplex Transmission (Example)

108-013

### 19.5.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the `MCSPI_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field). Transmission starts only after data is loaded into the `MCSPI_TXx` register.

Rule 1 and Rule 2, defined in Section 19.5.2.2, are applicable in this mode.

Rule 3, defined in Section 19.5.2.2, is not applicable.

In master transmit-only mode, the `MCSPI_RXx` register state FULL does not prevent transmission and the `MCSPI_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `SPIm.MCSPI_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `SPIm.MCSPI_CHxSTAT[2]` EOT bit.

### 19.5.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPI_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPI_RXx` register.

Rule 1 and Rule 3, defined in Section 19.5.2.2, are applicable in this mode.

Rule 2, defined in Section 19.5.2.2, is not applicable.

In the master receive-only mode, software must write dummy data to the `MCSPI_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the `MCSPI_TXx` register is always full (the `TXx_EMPTY` bits of `SPIm.MCSPI_IRQSTATUS`) when receiving. The content of the `MCSPI_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPI_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `SPIm.MCSPI_IRQSTATUS` register are never set in receive-only mode.

The SPIm.MCSPI\_CHxSTAT[2] EOT bit gives the status of serialization. The RXx\_FULL bits of the SPIm.MCSPI\_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI\_RXx register. The SPIm.MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

### 19.5.2.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel, the assertion of the spim\_csx signal can be controlled in two different ways:

- If the MCSPI\_MODULCTRL[0] SINGLE bit is set to 0, spim\_csx assertion/deassertion after each SPI word is automatically controlled by the McSPI module (see subsections of Section 19.5.2.1, *Master Mode Features*).
- If the MCSPI\_MODULCTRL[0] SINGLE bit and the MCSPI\_CHxCONF[20] FORCE bit are set to 1: spim\_csx assertion/deassertion is controlled by software (see Section 19.5.2.5.1, *Programming Tips When Switching to Another Channel*).

#### 19.5.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.MCSPI\_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

#### 19.5.2.5.2 Force spim\_csx Mode

Continuous transfers are manually allowed by keeping the spim\_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the spim\_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the spim\_csx active mode is supported when:

- A single channel is used (with the SPIm.MCSPI\_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.MCSPI\_CHxCONF).

The state of the spim\_csx signal is programmable.

- Writing 1 to the SPIm.MCSPI\_CHxCONF[20] FORCE bit drives the spim\_csx line high when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 0. spim\_csx is driven low when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 1.
- Writing 0 to the SPIm.MCSPI\_CHxCONF[20] FORCE bit drives the spim\_csx line low when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 0. spim\_csx is driven high when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the SPIm.MCSPI\_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the spim\_csx line.

When the channel is enabled, the spim\_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI\_TXx register (the SPIm.MCSPI\_CHxSTAT[1] TXS bit), the status of the MCSPI\_RXx register (the SPIm.MCSPI\_CHxSTAT[1] RXS bit), and the defined mode (the SPIm.MCSPI\_CHxCONF[13:12] TRM field) of the channel enabled.

The SPIm.MCSPI\_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx\_FULL bit in the SPIm.MCSPI\_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI\_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the spim\_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

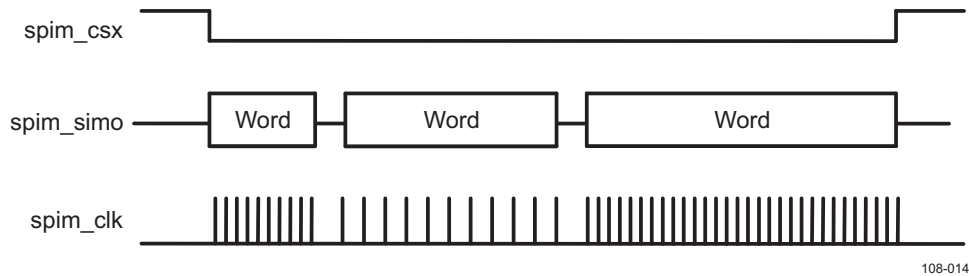

**Note:** To avoid data corruption, spim\_csx polarity and spim\_clk phase and spim\_clk polarity must not be modified when the spim\_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI\_CHxCTRL[0] EN bit set to 0) and spim\_csx can be forced to its inactive state using the SPIm.MCSPI\_CHxCONF[20] FORCE bit.

Figure 19-15 and Figure 19-16 show successive transfers with spim\_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 19-15. Continuous Transfers With spim\_csx Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 19-16. Continuous Transfers With spim\_csx Maintained Active (Dual-Data-Pin Interface Mode)**

**Note:** The turbo mode described in Section 19.5.2.5.3, *Turbo Mode*, maintains spim\_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI\_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The SPIm.MCSPI\_CHxCONF[19] TURBO bit is set to 1.)

### 19.5.2.5.3 Turbo Mode

The turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI\_RXx register are full. The turbo mode is useful (time savings) when a transfer exceeds two words. This mode is programmable per channel (via the SPI1.MCSPI\_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 applies, but Rule 3 does not (see [Section 19.5.2.2](#)). An enabled channel can be scheduled if its receive register is full (the SPIm.MCSPI\_CHxSTAT[0]) RXS bit) at the time of the shift-register assignment until the shift register is full.

The MCSPI\_RXx register cannot be overwritten in turbo mode. Consequently, the SPIm.MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

### 19.5.2.6 Start Bit Mode

In start bit mode, an extended bit is added before the SPI word in order to indicate whether the next SPI word must be handled as a command or as data. This feature is only available in master mode. The start bit mode cannot be used at the same time as turbo mode and/or force spim\_csx mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPIm.MCSPI\_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPIm.MCSPI\_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPIm.MCSPI\_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPIm.MCSPI\_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

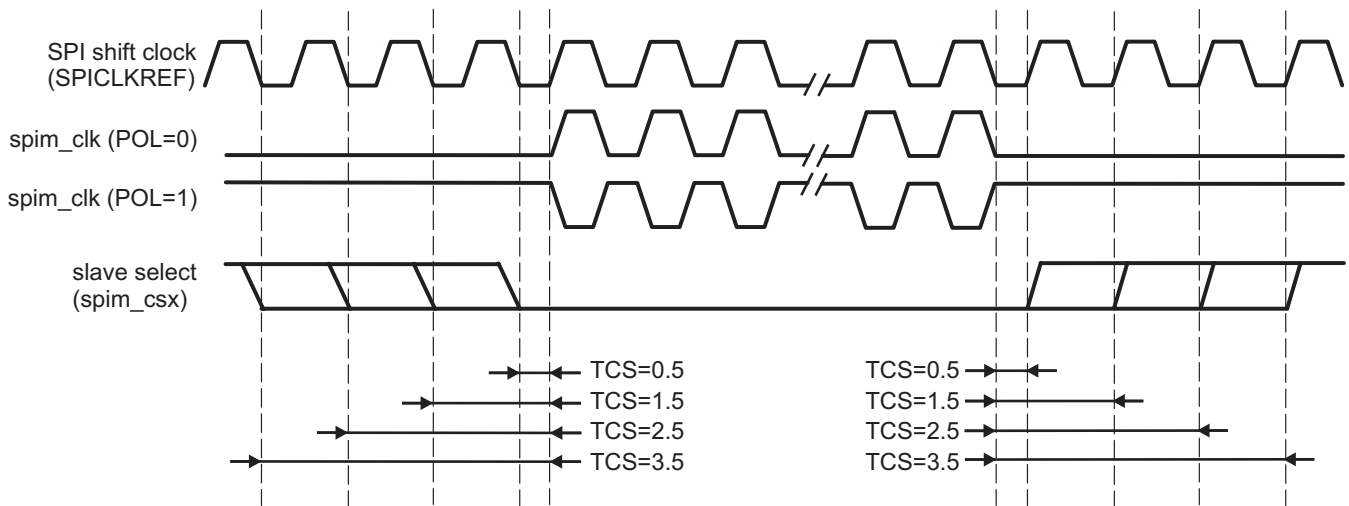

### 19.5.2.7 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (MCSPI\_MODULCTRL[0] SINGLE bit field set to 0), to add a programmable delay between chip select assertion and first clock edge, or chip select removal and last clock edge.

This mode is programmable per channel (the TCS bit of the SPIm.MCSPI\_CHxCONF register).

[Figure 19-17](#) shows the chip-select SPIEN timing control.

**Figure 19-17. Chip-Select SPIEN Timing Controls**

108-016

**Note:** Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

### 19.5.2.8 Programmable SPI Clock (spim\_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPI<sub>m</sub>\_FCLK, is used as input of a programmable divider (the SPI<sub>m</sub>.MCSPI\_CHxCONF[5:2] CLKD field) to generate the bit rate of the serial output clock spim\_clk. [Table 19-11](#) summarizes the supported divisor values.

**Table 19-11. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: division not supported	-

#### 19.5.2.8.1 Clock Ratio Granularity

By default the clock division ratio is defined by the SPI<sub>m</sub>.MCSPI\_CHxCONF[5:2] CLKD bit field with power of two granularity leading to a clock division in range 1 to 4096, in this case the duty cycle is always 50%. With the SPI<sub>m</sub>.MCSPI\_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle, in that case the SPI<sub>m</sub>.MCSPI\_CHxCTRL[15:8] EXTCLK bit field is concatenated with SPI<sub>m</sub>.MCSPI\_CHxCONF[5:2] CLKD bit field to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for odd value of clock ratio the clock high level lasts one clock cycle more than low level depending on SPI<sub>m</sub>.MCSPI\_CHxCONF[1] POL bit and SPI<sub>m</sub>.MCSPI\_CHxCONF[0] PHA bit refer to [Table 19-12](#).

**Table 19-12. CLKSPIO High/Low Time Computation**

Clock ratio Fratio	CLKSPIO High Time	CLKSPIO Low Time
1	T <sub>high_ref</sub>	T <sub>low_ref</sub>
Even ≥ 2	T <sub>ref</sub> * (Fratio/2)	T <sub>ref</sub> * (Fratio/2)
Odd ≥ 3 (POL=PHA)	T <sub>ref</sub> * (Fratio-1) / 2	T <sub>ref</sub> * (Fratio+1) / 2
Odd ≥ 3 (POL≠PHA)	T <sub>ref</sub> * (Fratio+1) / 2	T <sub>ref</sub> * (Fratio-1) / 2

**Note:** Fratio = spi1\_clk frequency (Fout) division ratio.  
 Thigh = spi1\_clk High Time period.  
 Tlow = spi1\_clk Low Time period.  
 T\_ref = SPI1\_FCLK period.  
 Thigh\_ref = SPI1\_FCLK high Time period.  
 Tlow\_ref = SPI1\_FCLK low Time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1 as shown below:

Fratio - 1											
11	10	9	8	7	6	5	4	3	2	1	0
SPI1.[15:8] EXTCLK bit field								SPI1.[5:2] CLKD bit field			
15	14	13	12	11	10	9	8	5	4	3	2

For odd ratio values, the duty cycle is calculated as below:

$$\text{Duty\_cycle} = (1 - 1/\text{Fratio})/2$$

Table 19-13 shows clock granularity examples with a clock source frequency of 48 MHz.

**Table 19-13. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50-50	48
X	1	0	2	X	X	20.8	20.8	41.6	50-50	24
X	2	0	4	X	X	41.6	41.6	83.2	50-50	12
X	3	0	8	X	X	83.2	83.2	166.4	50-50	6
0	0	1	1	X	X	10.4	10.4	20.8	50-50	48
0	1	1	2	X	X	20.8	20.8	41.6	50-50	24
0	2	1	3	1	0	41.6	20.8	62.4	66-33	16
0	2	1	3	1	1	20.8	41.6	62.4	33-66	16
0	3	1	4	X	X	41.6	41.6	83.2	50-50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6-49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50-50	0.545

### 19.5.3 Slave Mode

To select the McSPI slave mode, set the SPI1.MCSPI\_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (spim\_simo and spim\_somi) when it is selected by an active control signal (spim\_csx) and receives an SPI clock (spim\_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the McSPI uses the edge of spim\_csx to detect word length. For this reason, spim\_csx must become inactive between each word.

The McSPI does not support spim\_csx active between SPI words. It uses the edge to detect word length.

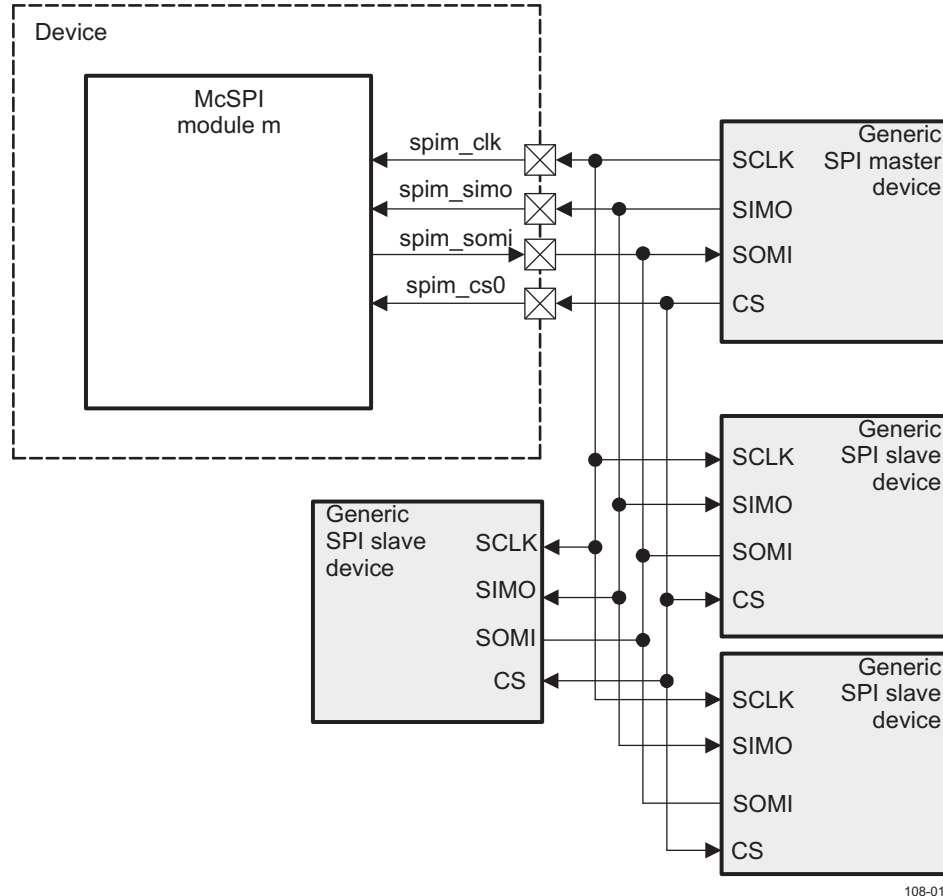

#### 19.5.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section registers name such as SPI1.MCSPI\_CHxCTRL stand for SPI1.MCSPI\_CH0CTRL where x=0 (channel 0 control register).

Figure 19-18 shows an example of four slaves wired on a single master device.

Figure 19-18. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

108-017

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI\_CHxCTRL[0] EN bit (with x=0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected only on spin\_cs0.
- Its own transmitter register, SPIm.MCSPI\_TXx (with x=0), on top of the common transmit shift register. If the MCSPI\_TXx register is empty, the SPIm.MCSPI\_CHxSTAT[1] TXS bit (with x=0) is set. If McSPI is selected by an external master (the active signal on the spim\_csx port assigned to channel 0), the MCSPI\_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI\_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI\_RXx (with x=0), on top of the common receive shift register. If the MCSPI\_RXx register is full, the SPIm.MCSPI\_CHxSTAT[0] RXS bit (with x=0) is set.

**Note:** The MCSPI\_TXx register and MCSPI\_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm.MCSPI\_CHxCONF register (with x=0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
  - SPI word length, programmable with the WL bit
  - spim\_csx polarity, programmable with the EPOL bit
  - spim\_clk polarity, programmable with the POL bit

- spim\_clk phase, programmable with the PHA bit

The spim\_clk frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The SPIm.MCSPI\_CHxCONF[5:2] CLKD field (with x=0) is not used in slave mode.

---

**Note:** The configuration of the channel can be loaded in the SPIm.MCSPI\_CHxCONF register (with x=0) only when the channel is disabled.

---

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the SPIm.MCSPI\_CHxCONF[15] DMAR bit (with x=0) for reading and the SPIm.MCSPI\_CHxCONF[14] DMAW bit (with x=0) for writing.
- Four interrupt events (see [Section 19.5.5.2, Interrupt Events in Slave Mode](#))

### 19.5.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI\_CHxCONF[13:12] TRM field (with x=0) to 0x0).

In slave transmit-and-receive mode, the MCSPI\_Tx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI\_Tx register content is always loaded in the shift register whether it is updated or not. The event TXx\_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI\_CHxSTAT0[2] EOT bit (with x=0) set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the Rx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI\_Rx register state (see [Section 19.5.5.2, Interrupt Events in Slave Mode](#)).

### 19.5.3.3 Slave Transmit-Only Mode

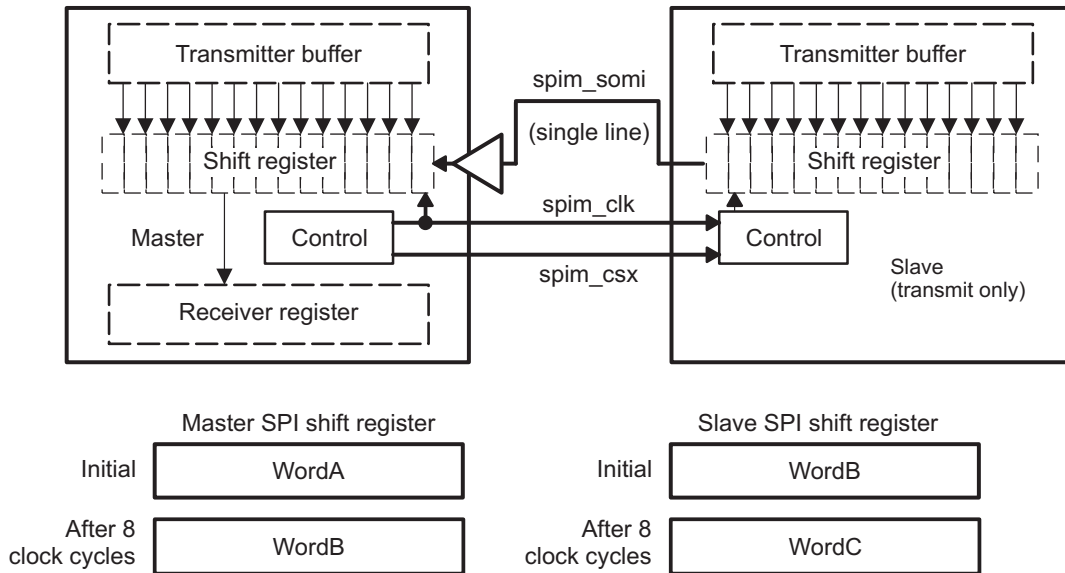

The slave transmit-only mode is programmable (set the SPIm.MCSPI\_CHxCONF[13:12] TRM field (with x=0) to 0x2) and avoids the requirement for the MPU to read the MCSPI\_Rx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the Rx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled because of the MCSPI\_Rx register state.

When the SPI word transfer completes, the SPIm.MCSPI\_CHxSTAT[2] EOT bit is set (with x=0).

[Figure 19-19](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim\_clk, WordB transfers from the slave to the master.

**Figure 19-19. SPI Half-Duplex Transmission (Transmit-Only Slave)**

108-031

#### 19.5.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `SPIm.MCSPI_CHxCONF[13:12]` TRM field (with `x=0`) to `0x1`).

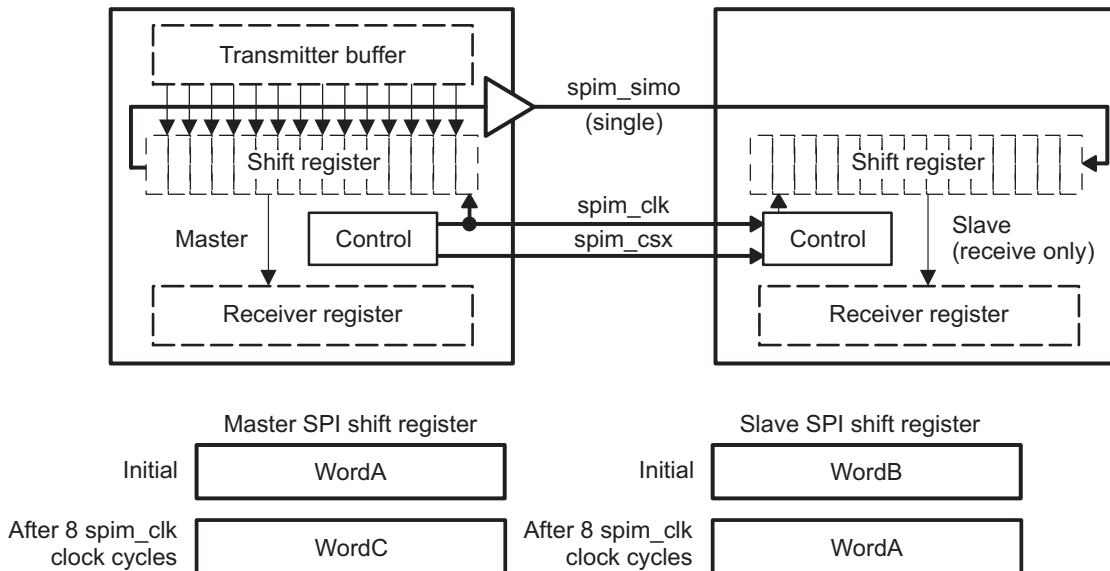

In receive-only mode, the `MCSPI_TXx` register must be loaded before the McSPI is selected by an external SPI master device. The `MCSPI_TXx` register content is always loaded into the shift register whether it is updated or not. The `TXx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the `SPIm.MCSPI_CHxSTAT0[2]` EOT bit (with `x=0`) is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the `TXx_EMPTY` and `TXx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the `MCSPI_TXx` register state.

For a full-duplex transmission, the serial clock (`spim_clk`) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If `spim_clk` synchronizes on a single serial data line, the data line should be half-duplex.

Figure 19-20 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock `spim_clk`, Word A transfers from the master to the slave.

**Figure 19-20. SPI Half-Duplex Transmission (Receive-Only Slave)**

108-032

### 19.5.4 FIFO Buffer Management

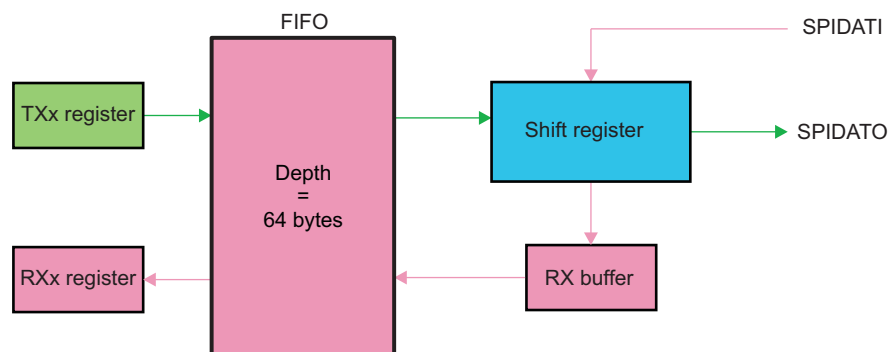

The McSPI controller has a built-in 64 bytes buffer to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at once and is selected by setting `SPI.MCSPI_CHxCONF[28]` FFER bit or `SPI.MCSPI_CHxCONF[27]` FFEW bit to 1. If several channels are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined below:

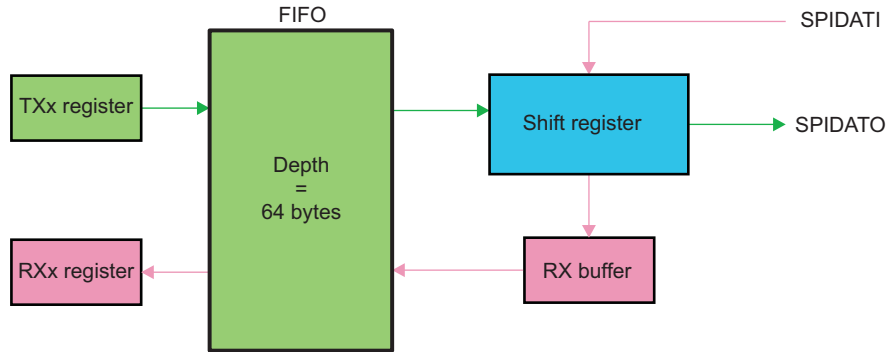

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length `SPI.MCSPI_CHxCONF[11:7]` WL are supported.

In transmit/receive mode, the buffer can be used in transmit (see [Figure 19-21](#)) or receive (see [Figure 19-22](#)) directions, or in both directions. If only one direction is chosen in transmit/receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction. See [Figure 19-23](#).

**Figure 19-21. Buffer Use in Transmit Direction Only**

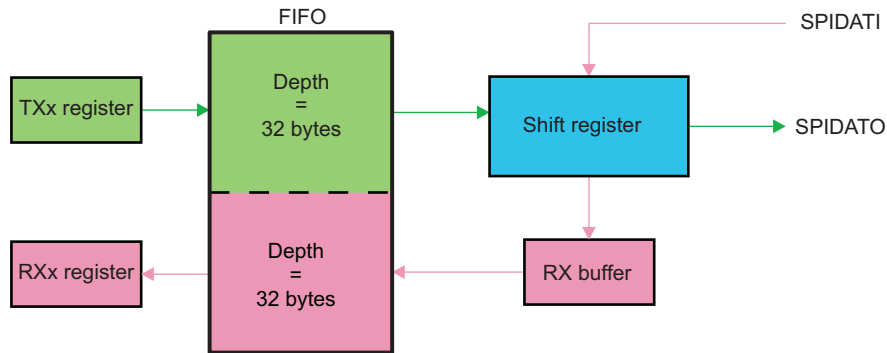

mcspi-102

Figure 19-22. Buffer Use in Receive Direction Only

mcspi-103

Figure 19-23. Buffer Used For Both Transmit/Receive Directions

mcspi-101

Two levels SPIm.MCSPI\_XFERLEVEL[5:0] AEL and SPIm.MCSPI\_XFERLEVEL[13:8] AFL rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in WL. Table 19-14 shows the number of byte written in the FIFO depending on the word length.

Table 19-14. FIFO Writes, Word Length Relationship

SPI Word Length WL	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

#### 19.5.4.1 Buffer Almost Full

The MCSPI\_XFERLEVEL[13:8] AFL bit field is needed when the buffer is used to receive SPI word from a slave (MCSPI\_CHxCONF[28] FFER bit must be set to 1). It defines the Almost Full buffer status. See Figure 19-24.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable system to read AFL+1 bytes from Receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI\_CHxCONF[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

**Figure 19-24. Buffer Almost Full Level (AFL)**

**Note:** [MCSPi\\_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm\\_DMA\\_RXx](#) request is asserted on the same conditions than the [MCSPi\\_IRQSTATUS](#) [RXx\\_FULL](#) flag.

#### 19.5.4.2 Buffer Almost Empty

The [MCSPi\\_XFERLEVEL](#)[5:0] AEL bit field is needed when the buffer is used to transmit SPI word to a slave ([MCSPi\\_CHxCONF](#)[27] FFEW bit must be set to 1). It defines the Almost Empty buffer status. See [Figure 19-25](#).

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the MPU to enable system to write AEL+1 bytes to Transmit register. Be careful AEL+1 must correspond to a multiple value of [MCSPi\\_CHxCONF](#)[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

**Figure 19-25. Buffer Almost Empty Level (AEL)**

**Note:** [MCSPi\\_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm\\_DMA\\_TXx](#) request is asserted on the same conditions than the [MCSPi\\_IRQSTATUS](#) [TXx\\_EMPTY](#) flag.

### 19.5.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure in the [MCSPI\\_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPI\\_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user does not know how many SPI transfers have been done. For received words, software shall poll the CHxSTAT[5] RXFFE bit and read the [MCSPI\\_RXx](#) Receive register to empty the FIFO buffer.

When the End Of Word count interrupt is generated ([MCSPI\\_IRQSTATUS\[17\]](#) EOW bit set), the user can disable the channel and poll the [MCSPI\\_CHxSTAT\[5\]](#) RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted again as long as system has not performed the right number of write accesses.

## 19.5.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.[MCSPI\\_IRQSTATUS](#) register (RXx\_FULL, TXx\_UNDERFLOW, TXx\_EMPTY, ...) with x = [0,3] that indicate if service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.[MCSPI\\_IRQENABLE](#) register (RXx\_FULL\_ENABLE, TXx\_UNDERFLOW\_ENABLE, TXx\_EMPTY\_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

### 19.5.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the [MCSPI\\_TXx](#) register state are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt event related to the [MCSPI\\_RXx](#) register state is RXx\_FULL.

#### 19.5.5.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its [MCSPI\\_TXx](#) register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see [Section 19.5.2.4, Master Receive-Only Mode](#)). When the FIFO buffer is enabled ([MCSPI\\_CHxCONF\[27\]](#) FFEW bit set to 1), the [MCSPI\\_IRQSTATUS](#) TXx\_EMPTY bit is set as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI\\_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPI\\_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI\\_IRQSTATUS](#) TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI\\_TXx](#) register defined by [MCSPI\\_XFERLEVEL\[5:0\]](#) AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

#### 19.5.5.1.2 TXx\_UNDERFLOW

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the [MCSPI\\_TXx](#) register or if the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx\_UNDERFLOW is a harmless warning in master mode.

To avoid having TXx\_UNDERFLOW event at the beginning of a transmission, the event TXx\_UNDERFLOW is not activated when no data has been loaded into the MCSPI\_TXx register since channel has been enabled. To avoid having TXx\_UNDERFLOW event, the MCSPI\_TXx register must be loaded seldom.

The SPI.MCSPi\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

### 19.5.5.1.3 RXx\_FULL

The RXx\_FULL event is activated when channel is enabled and MCSPI\_RXx register becomes filled (transient event). When FIFO buffer is enabled (MCSPI\_CHxCONF[28] FFER bit set to 1), the RXx\_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13:8] AFL threshold.

The MCSPI\_RXx register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into MCSPI\_RXx. It is the responsibility of MPU to perform the right number of reads.

### 19.5.5.1.4 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the MCSPI\_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enable and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

## 19.5.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the MCSPI\_TXx register state are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt events related to the MCSPI\_RXx register state are RXx\_FULL and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI\_IRQSTATUS register.

### 19.5.5.2.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (MCSPI\_CHxCONF[27] FFEW bit set to 1), the TXx\_EMPTY event is asserted as soon as there is enough space in buffer to write a number of byte defined by the MCSPI\_XFERLEVEL[5:0] AEL bit field.

The MCSPI\_TXx register must be loaded with data to remove the source of the interrupt; the SPI.MCSPi\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI\_TXx register defined by MCSPI\_XFERLEVEL[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

### 19.5.5.2.2 TXx\_UNDERFLOW

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the MCSPI\_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data if the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when data is not loaded into the [MCSPI\\_TXx](#) register because the channel is enabled.

The SPIm.[MCSPI\\_IRQSTATUS](#) TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

### 19.5.5.2.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the [MCSPI\\_RXx](#) register is being filled (transient event). When FIFO buffer is enabled ([MCSPI\\_CHxCONF](#)[28] FFER bit set to 1), RXx\_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by the [MCSPI\\_XFERLEVEL](#)[13:8] AFL bit field.

The [MCSPI\\_RXx](#) register must be read to remove the source of the interrupt; the SPIm.[MCSPI\\_IRQSTATUS](#) RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI\\_RXx](#). It is the responsibility of MPU to perform the right number of reads.

### 19.5.5.2.4 RX0\_OVERFLOW

The RX0\_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the [MCSPI\\_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI\\_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0\_OVERFLOW indicates an error (data loss) in slave mode.

The [MCSPI\\_IRQSTATUS](#)[3] RX0\_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

### 19.5.5.2.5 End Of Word Count

The [MCSPI\\_IRQSTATUS](#)[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI\\_XFERLEVEL](#)[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The [MCSPI\\_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

## 19.5.5.3 Interrupt-Driven Operation

An interrupt enable bit, in SPIm.[MCSPI\\_IRQENABLE](#) register, can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

- Read the SPIm.[MCSPI\\_IRQSTATUS](#) register to identify which event occurred.

- Read the [MCSPI\\_RXx](#) register that corresponds to the event to remove the source of an RXx\_FULL event or write into the [MCSPI\\_TXx](#) register that corresponds to the event to remove the source of a TXx\_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx\_UNDERFLOW, and RX0\_OVERFLOW events.
- Write 1 into the corresponding bit of the SPIm.[MCSPI\\_IRQSTATUS](#) register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 19.5.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.[MCSPI\\_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the SPIm.[MCSPI\\_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx\_FULL: To remove the source of the event, the MPU must read the corresponding [MCSPI\\_RXx](#) register.
- TXx\_EMPTY: To remove the source of the event, the MPU must write into the corresponding [MCSPI\\_TXx](#) register.
- WKS (wake-up), TXx\_UNDERFLOW, and RX0\_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.[MCSPI\\_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

#### 19.5.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each McSPI channel can issue DMA requests if they are enabled. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.[MCSPI\\_CHxCONF](#)[15] DMAR bit. The DMA read request line is deasserted on read completion of the [MCSPI\\_RXx](#) register of the McSPI channel.

The DMA write request line is asserted when the McSPI channel is enabled and the [MCSPI\\_TXx](#) register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.[MCSPI\\_CHxCONF](#)[14] DMAW bit. The DMA write request line is deasserted on load completion of the [MCSPI\\_TXx](#) register of the channel.

#### 19.5.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

##### 19.5.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.[MCSPI\\_SYSCONFIG](#)[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

### 19.5.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE\_48M\_FCLK or CORE\_L4\_ICLK output clocks (see [Chapter 4, Power, Reset, and Clock Management](#), for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM idle request is configurable through the McSPI.SYSCONFIG[4:3] SIDLEMODE bit.

The following list details the settings of the SIDLEMODE bit and the related acknowledgment modes:

- Force-idle mode (the SPIm.MCSPI\_SYSCONFIG[4:3] SIDLEMODE bit set to 0x0): the McSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit set to 0x1): The McSPI module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The McSPI module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the McSPI module also offers an additional granularity on the CORE\_48M\_FCLK and CORE\_L4\_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE\_48M\_FCLK, the CORE\_L4\_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to McSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE\_48M\_FCLK is not shut down on a PRCM idle request, McSPI considers only CORE\_L4\_ICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with CORE\_L4\_ICLK and others with CORE\_48M\_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if McSPI acknowledges an idle request.

The following list details CLOCKACTIVITY settings and the associated features:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, both ICLK and FCLK are taken into account for generating the acknowledge. This setting also means that both FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means McSPI can potentially acknowledge the idle request without checking the internal functionalities linked to its clocks.

**CAUTION**

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, the software must ensure consistent programming between the CLOCKACTIVITY and the PRCM CORE\_48M\_FCLK and CORE\_L4\_ICLK control bits. If the McSPI is disabled in both the CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

**19.5.7.2.1 Wake-Up Event in Smart-Idle Mode**

The module wake-up feature is enabled when both the SPIm.MCSPY\_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPY\_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch the interface clock and the functional clock back. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the spim.csx port associated with channel 0 (see the definition for the SPIm.MCSPY\_CHxCONF SPIENSLV field (with x=0) in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- *Before the beginning* of the second SPI word serialization when McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- *Before the end* of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPY\_RXx register (with x=0) before the completion of the second SPI word serialization.

Table 19-15 lists the supported cases in wake-up mode.

**Table 19-15. Smart-Idle Mode and Wake-Up Capabilities**

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode.	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the spim.csx port associated to channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

**19.5.7.2.2 Transitions From Smart-Idle Mode to Normal Mode**

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPY\_IRQSTATUS[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPY\_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SPIm.MCSPi\_IRQENABLE and SPIm.MCSPi\_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPi\_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

### 19.5.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPi\_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0. In force-idle mode, McSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if both the SPIm.MCSPi\_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPi\_WAKEUPENABLE[0] WKEN bits are set.

The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPi\_IRQSTATUS register.

In force-idle mode, the module must be disabled so the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. The software must avoid such a request.

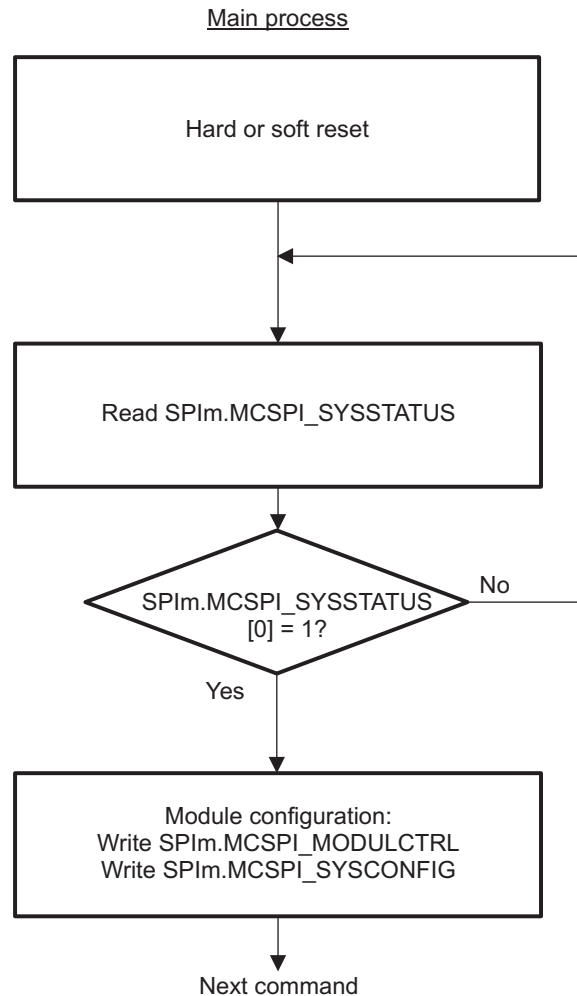

- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

## 19.6 McSPI Basic Programming Model

### 19.6.1 Initialization of Modules

Figure 19-26 shows the overview of the module initialization flow process. Section 19.6.2 and Section 19.6.3 show the steps required to configure McSPI modes.

**Figure 19-26. Module Initialization Flow**

**Note:** Before the SPIm.MCSPI\_SYSSTATUS[0] RESETDONE bit is set, the CLK and CLKSPIREF clocks must be provided to the module.

To avoid unpredictable behavior, reset the module before changing from master mode to slave mode, or vice versa.

### 19.6.2 Transfer Procedures without FIFO

In the subsections below, the transfer procedures are described without FIFO using (MCSPI\_CHxCONF[27:28] FFER and FFEW = 0).

The McSPI allows the transfer of one or more words based on the different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

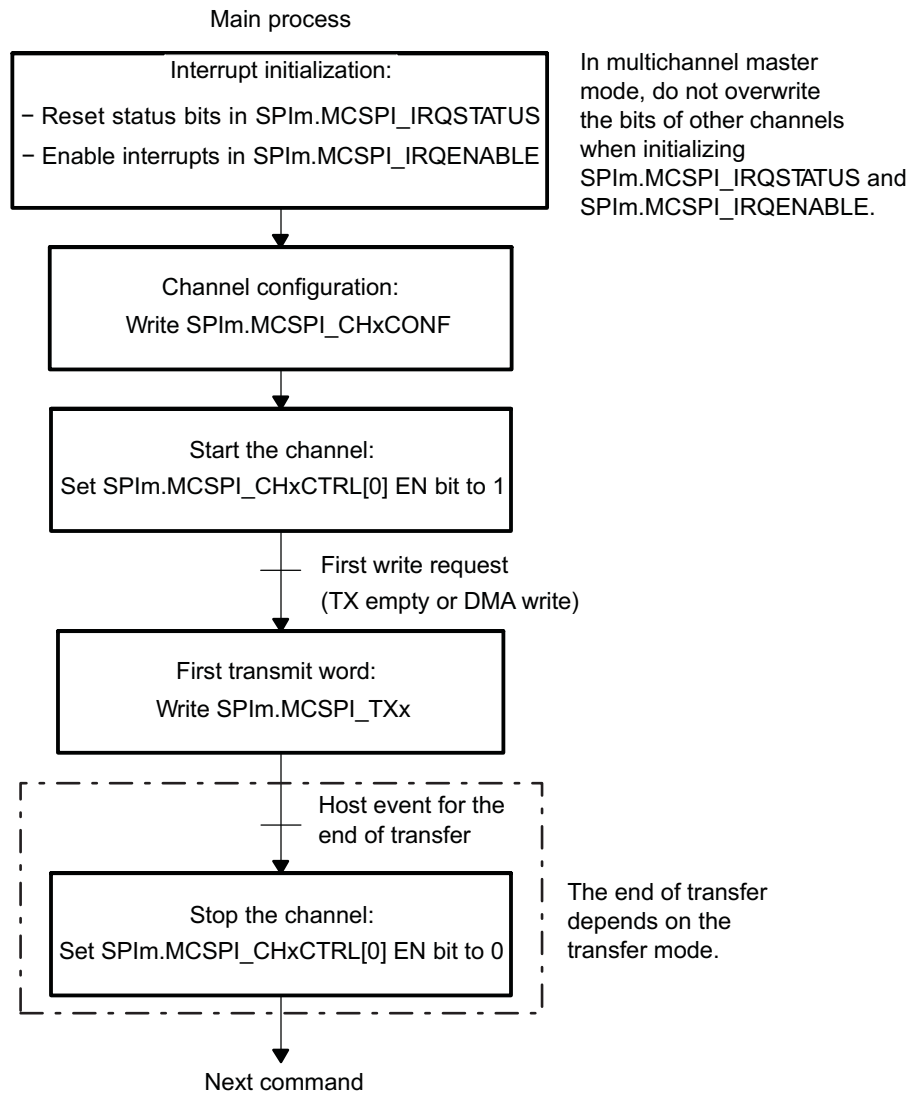

- spi1\_csx line assertion/deassertion: Automatic, manual

For these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

### 19.6.2.1 Common Transfer Procedure

Figure 19-27 shows the main sequence common to all transfers. In multichannel master mode, the flows of different channels can be run simultaneously.

**Figure 19-27. Common Transfer Sequence: Main Process**

108-030

### 19.6.2.2 End-of-Transfer Procedure

For transfers carried out with DMA or interrupt mode, the end of transfer must be achieved by following the steps shown in the flowcharts corresponding to Table 19-16, which summarizes the end-of-transfer types per transfer mode and provides cross-references for further information.

**Table 19-16. End-of-Transfer Sequences**

		Transmit Receive		Transmit Only		Receive Only	
		Interrupt	DMA	Interrupt	DMA	Interrupt	DMA
Master normal	End of transfer sequence	See <a href="#">Section 19.6.2.3</a>		See <a href="#">Section 19.6.2.4</a>		See <a href="#">Section 19.6.2.5.1</a>	See <a href="#">Section 19.6.2.5.1</a>
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size <sup>(1)</sup>		w		w		w - 1
Master turbo	End of transfer sequence	See <a href="#">Section 19.6.2.3</a>		See <a href="#">Section 19.6.2.4</a>		See <a href="#">Section 19.6.2.5.2</a>	See <a href="#">Section 19.6.2.5.2</a>
	Minimum number of words	1	1	1	1	2	3
	DMA transfer size <sup>(1)</sup>		w		w		w - 2
Slave	End of transfer sequence	See <a href="#">Section 19.6.2.3</a>		See <a href="#">Section 19.6.2.4</a>		See <a href="#">Section 19.6.2.5.3</a>	
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size <sup>(1)</sup>		w		w	w	w

<sup>(1)</sup> w = number of words to transfer

The different sequences can be merged in one process to manage transfers of several types. The end-of-transfer sequences are described from the start of the channel.

In these sequences and in later sections of this chapter, some software variables are used:

- WRITE\_COUNT (= 0 at initialization): Contains the number of words to transfer
- READ\_COUNT (= 0 at initialization): Contains the number of words to receive
- CHANNEL\_ENABLE (= false at initialization)
- LAST\_TRANSFER (= false at initialization): Indicates that the last word is in transmission
- LAST\_REQUEST (= false at initialization): Indicates that the last request is in progress

All variables are initialized before starting the channel.

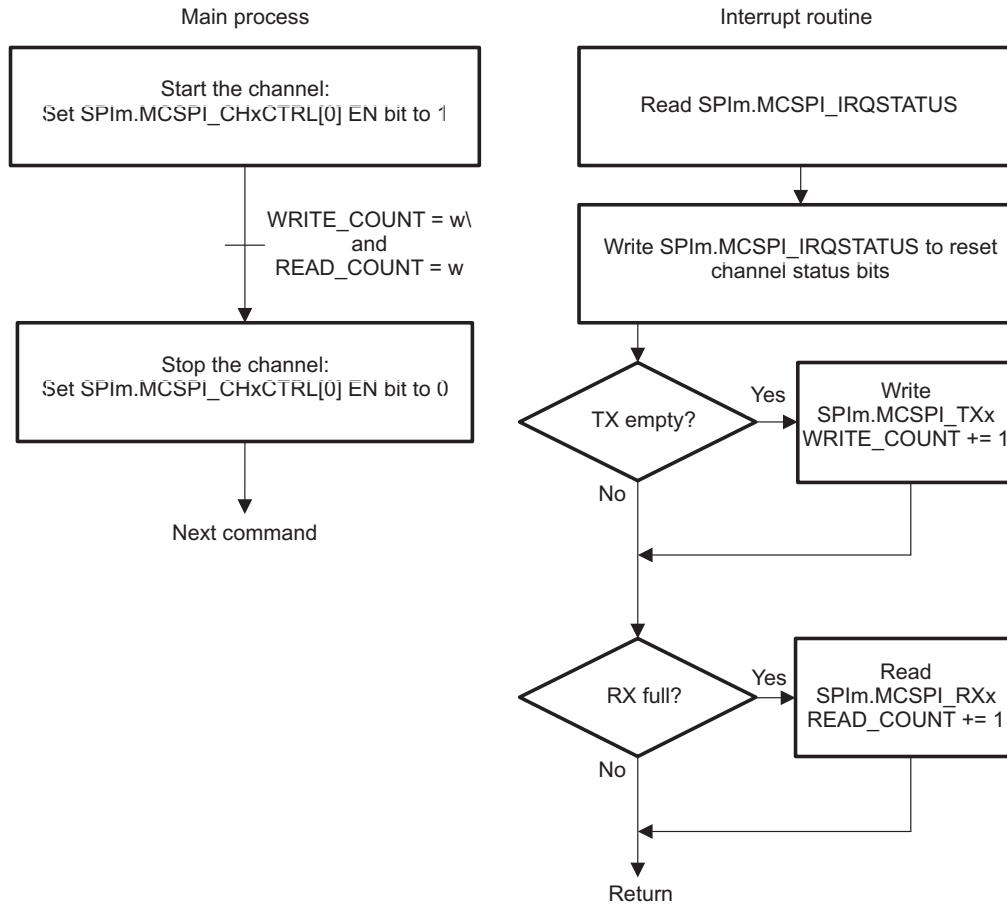

19.6.2.3 Transmit and Receive Procedure

Figure 19-28 shows the handling procedure for words received and transmitted by interrupt in master and slave modes. The main process flow shows how the end of the transfer must be done after all words are received for this mode.

If the requests are configured in DMA, WRITE\_COUNT and READ\_COUNT are assigned with the value w when the DMA handler completes w interface accesses.

Figure 19-28. Transmit and Receive (Master and Slave)

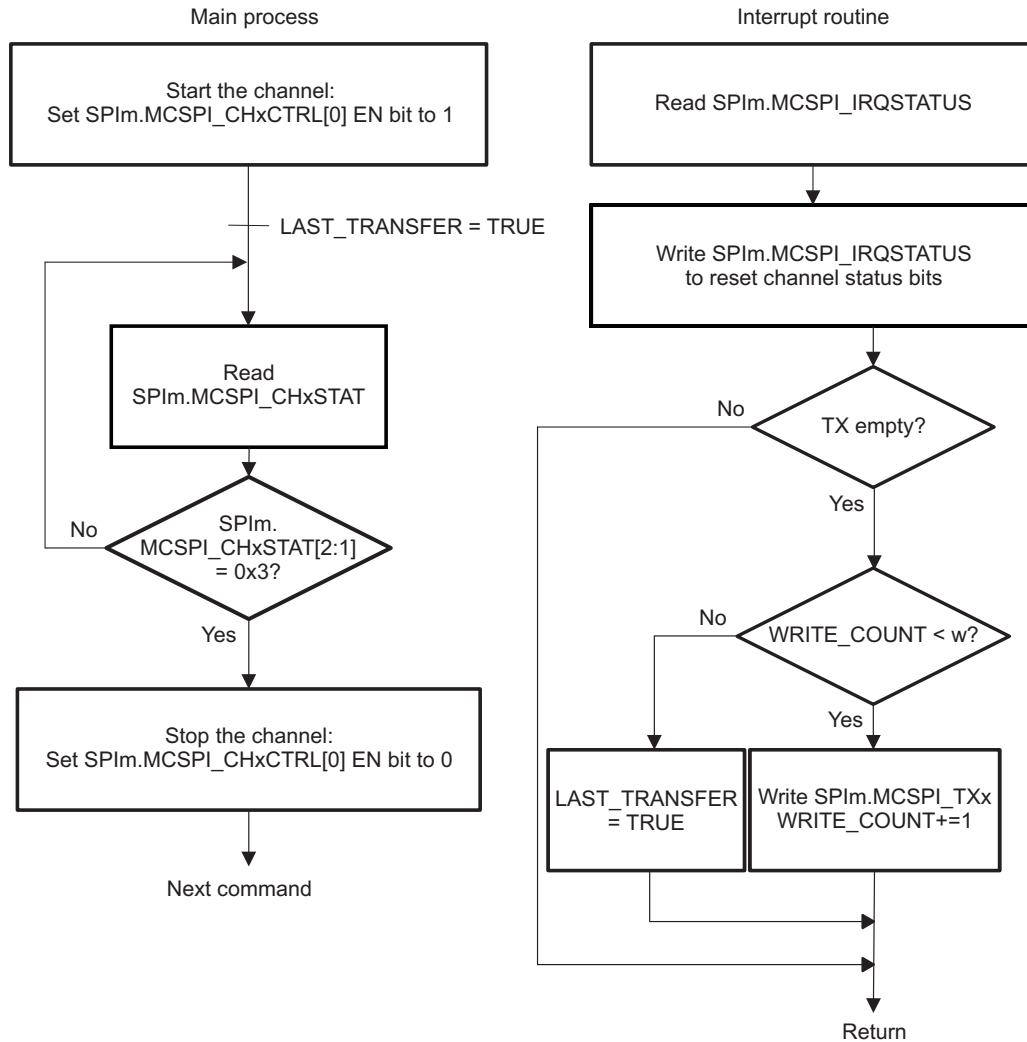

108-033

### 19.6.2.4 Transmit-Only Procedure

#### 19.6.2.4.1 Based on Interrupt Requests

Figure 19-29 shows the handling procedure for words transmitted by interrupt in transmit-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

**Figure 19-29. Transmit-Only With Interrupts (Master and Slave)**

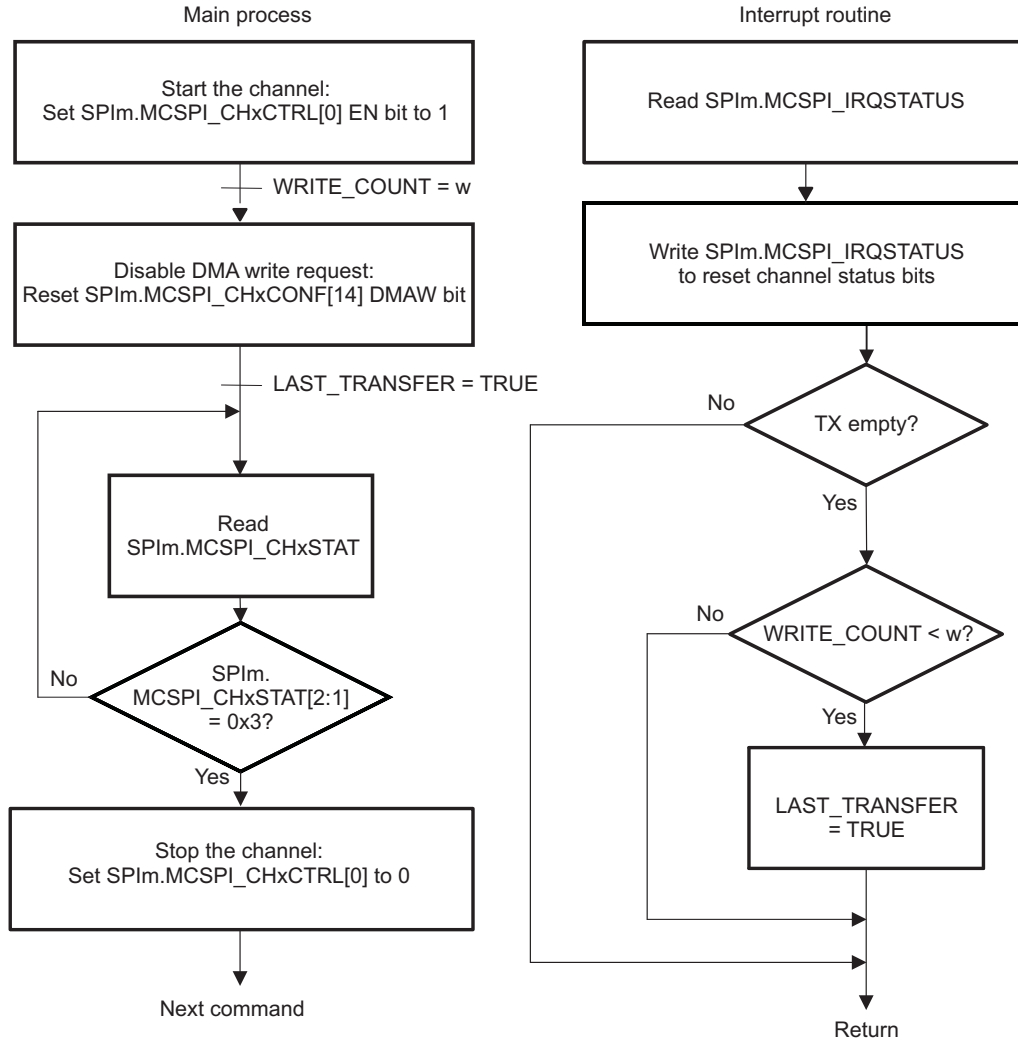

108-023

#### 19.6.2.4.2 Transmit-Only Based on DMA Write Requests

In Figure 19-30, the main process shows completion of the transfer of words in transmit-only mode with DMA write requests.

When the DMA handler completes  $w$  interface accesses, WRITE\_COUNT is assigned the value  $w$ .

**Figure 19-30. Transmit-Only With DMA (Master and Slave)**

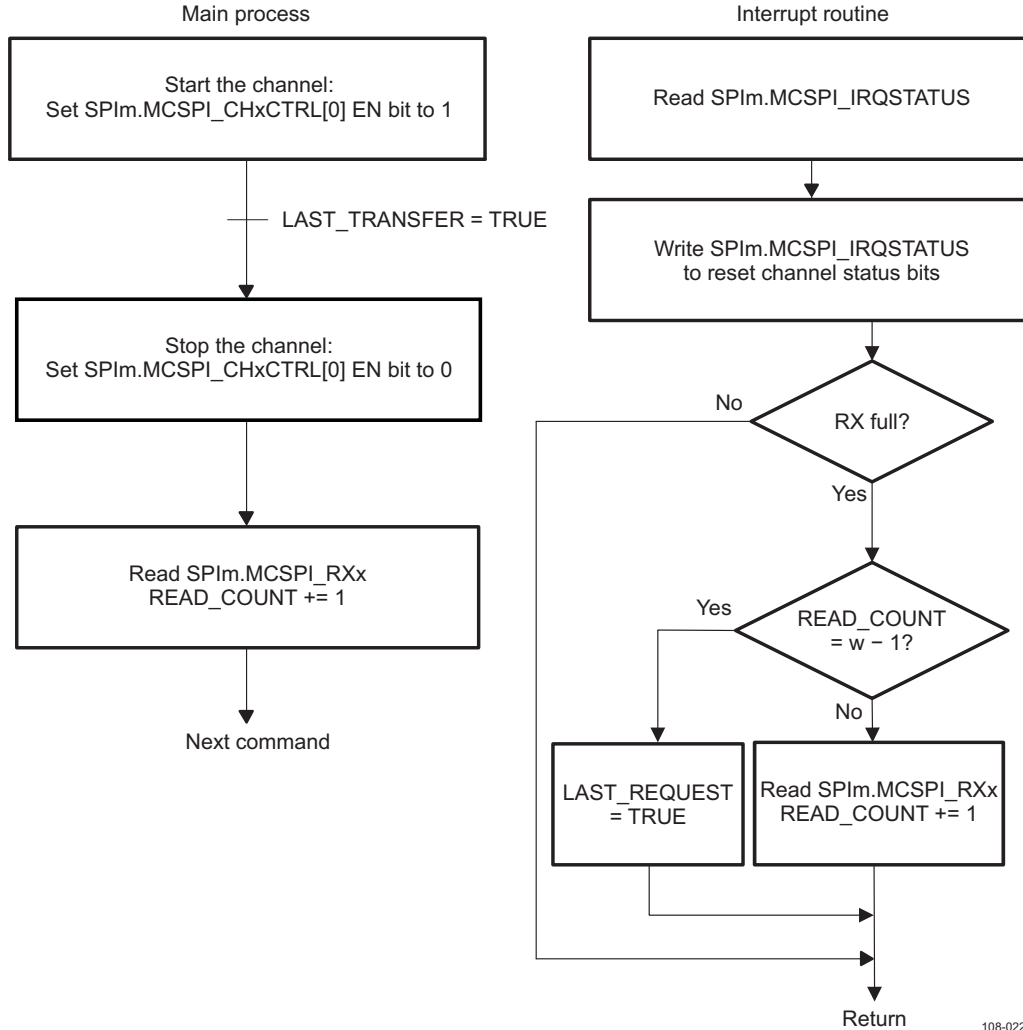

108-024

### 19.6.2.5 Receive-Only Procedure

#### 19.6.2.5.1 Master Normal Receive-Only Procedure

##### 19.6.2.5.1.1 Based on Interrupt Requests

Figure 19-31 shows the handling procedure for words received by interrupt in master normal receive-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

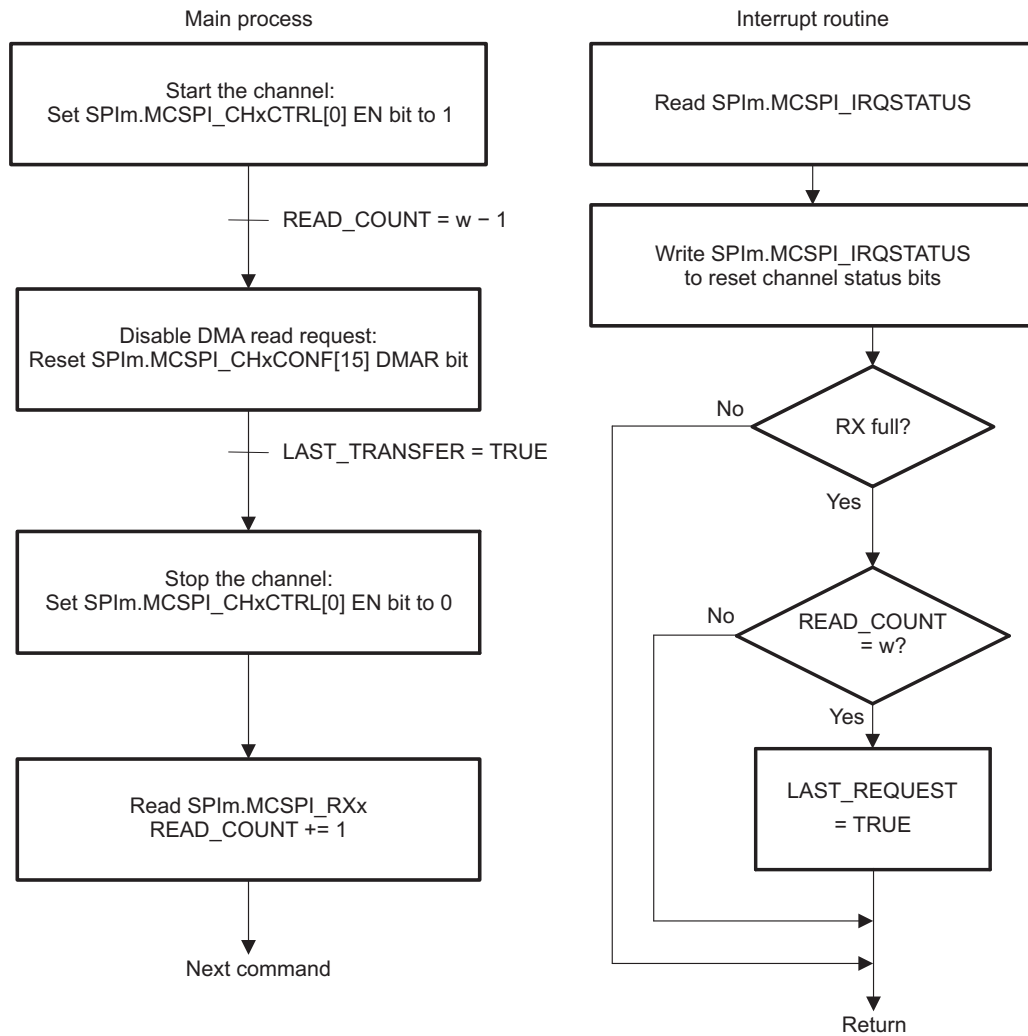

**Figure 19-31. Receive Only With Interrupt (Master Normal)**

#### 19.6.2.5.1.2 Receive-Only Based on DMA Read Requests

In [Figure 19-32](#), the main process shows the completion of a word transfer in receive-only mode with DMA read requests.

When the DMA handler completes  $w - 1$  interface accesses, READ\_COUNT is assigned the value  $w - 1$ .

**Figure 19-32. Receive-Only With DMA (Master Normal)**

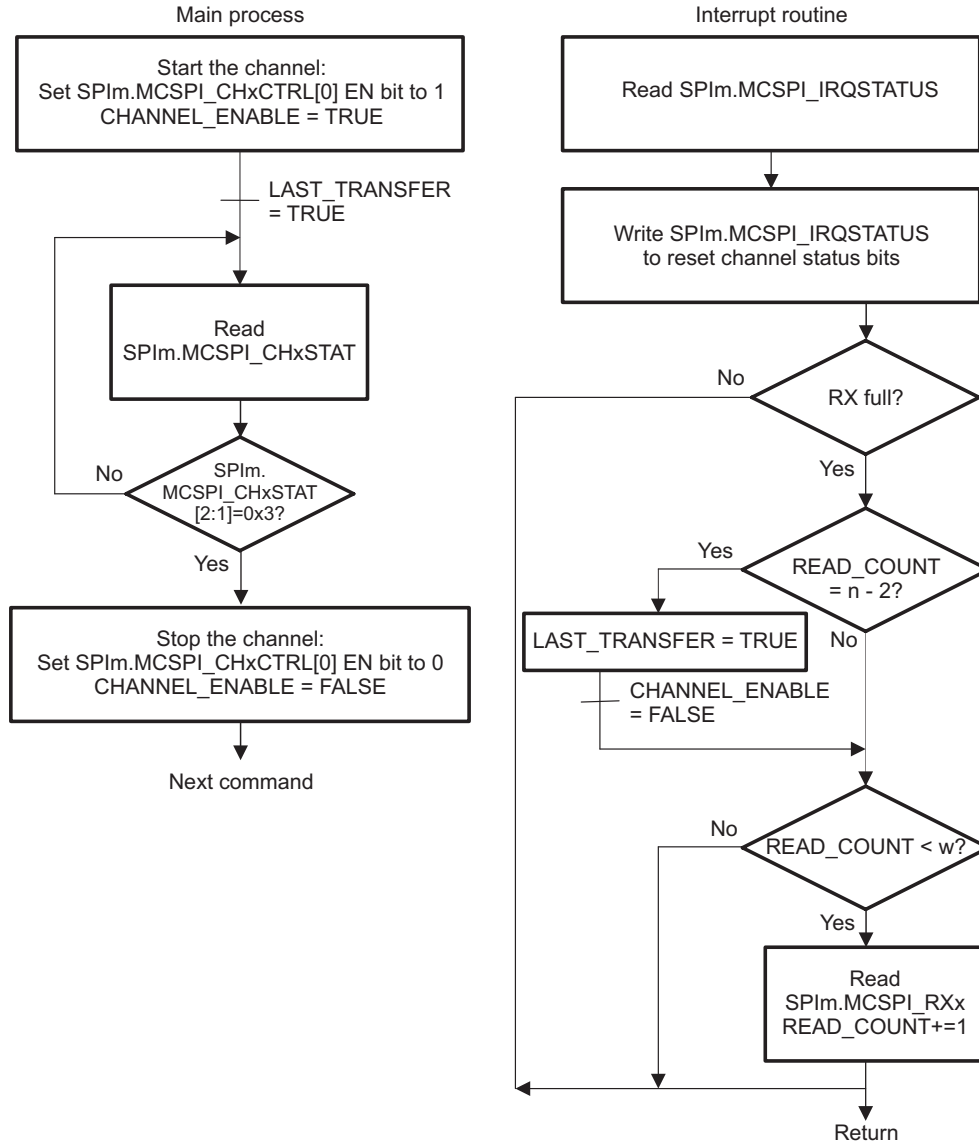

mspi-025

### 19.6.2.5.2 Master Turbo Receive-Only Procedure

#### 19.6.2.5.2.1 Based on Interrupt Requests

Figure 19-33 shows the handling procedure for words received by interrupt in master turbo receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

**Figure 19-33. Receive-Only With Interrupt (Master Turbo)**

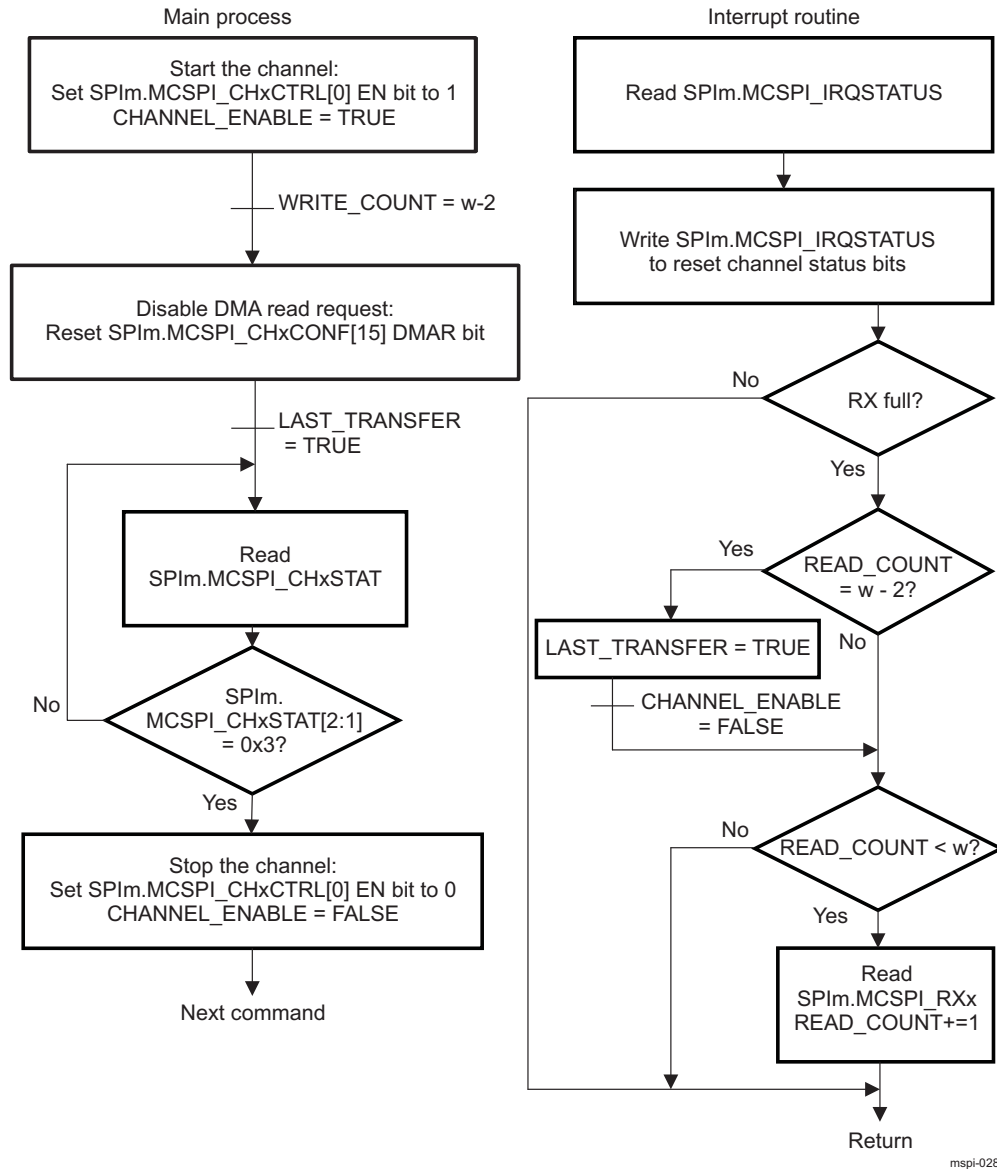

108-027

**19.6.2.5.2.2 Based on DMA Read Requests**

In [Figure 19-34](#), the main process shows the completion of a word reception in master turbo receive-only mode with DMA write requests.

When the DMA handler completes  $w - 2$  interface accesses, READ\_COUNT is assigned the value  $w - 2$ .

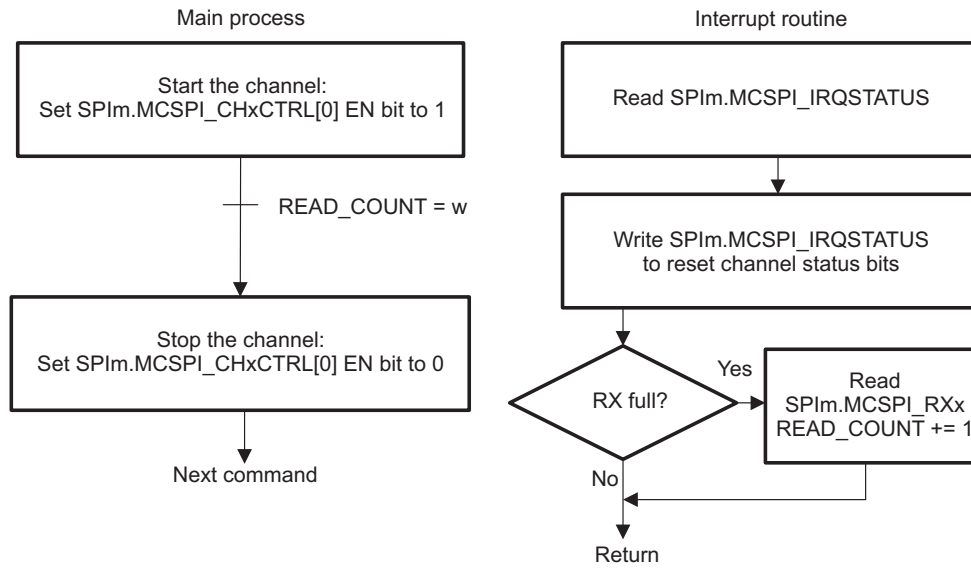

**Figure 19-34. Receive-Only With DMA (Master Turbo)**

### 19.6.2.5.3 Slave Receive-Only Procedure

Figure 19-35 shows the handling procedure for words received by interrupt in slave receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

If the requests are configured in DMA, READ\_COUNT is assigned the value w when the DMA handler completes w interface processes.

**Figure 19-35. Receive Only (Slave)**

108-035

### 19.6.2.6 McSPI Configuration and Operations Example

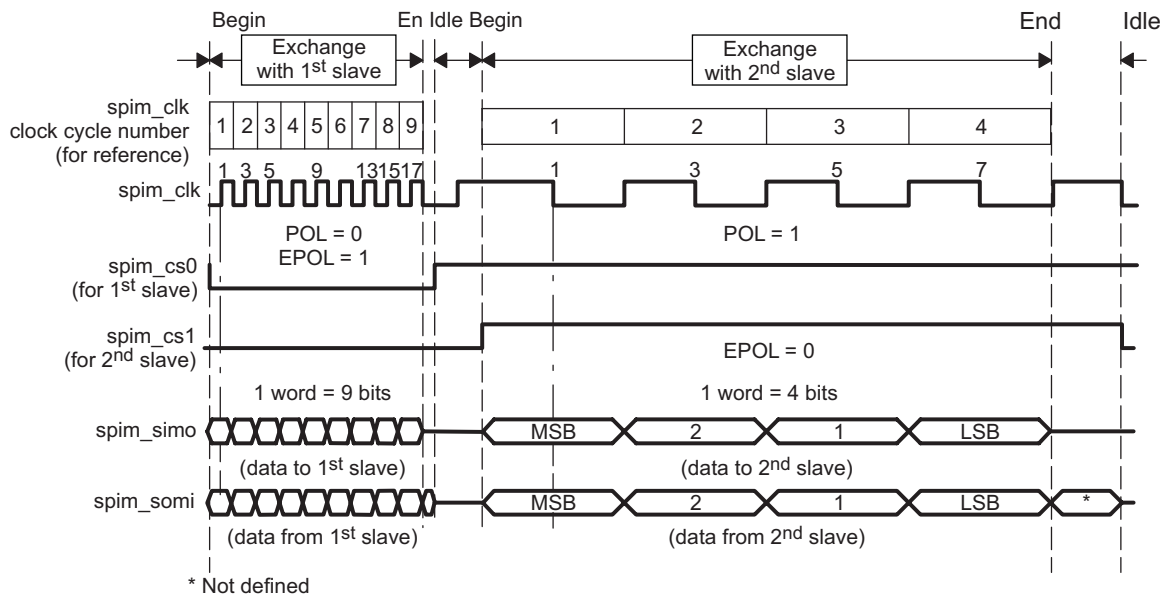

This section details an example of a typical configuration.

Figure 19-36 shows an implementation of successive transfers between two devices (slave) and the McSPI1 (master) in transmit-and-receive mode.

McSPI1 is the master, and spi1\_simo shifts out the data to the external slaves. spi1\_somi is connected to the data output port of two slave devices. The McSPI1 controls the first device with the spi1\_cs0 signal (active low) for the exchange of 9-bit words synchronized with an active-high SPI clock.

The second device is controlled by the spi1\_cs1 control signal (active high) for the exchange of 4-bit words synchronized with a SPI clock (active low) with a slower frequency than used with the first slave device.

Figure 19-36. Two SPI Transfers With PHA = 0 (Flexibility of McSPI)

mcspi-036

This section details the steps required for this type of transmission.

#### 19.6.2.6.1 McSPI Initialization Sequence

As shown in Figure 19-26, the McSPI module must first reset all registers and all state-machines.

For a software reset:

1. Set the SPI1.MCSPI\_SYSCONFIG[1] SOFTRESET bit to 1.
2. Read the SPI1.MCSPI\_SYSSTATUS[0] RESETDONE bit and check that it is set to 1.

#### 19.6.2.6.2 Operations for the First Slave (On Channel 0)

##### 19.6.2.6.2.1 Programming in Polling Mode

###### 19.6.2.6.2.1.1 Mode Selection

The SPI1.MCSPI\_CHxCONF register (with x = 0) allows configuration of the operating mode:

1. Set the SPI1.MCSPI\_CHxCONF[18] IS bit to 0 for the spi1\_somi pin in receive mode.
2. Set the SPI1.MCSPI\_CHxCONF[17] DPE1 bit to 0 and the SPI1.MCSPI\_CHxCONF[16] DPE0 bit to 1 for the spi1.simo pin in transmit mode.
3. Set the SPI1.MCSPI\_CHxCONF[13:12] TRM field to 0x0 for transmit and receive mode.
4. Write 0x8 in the SPI1.MCSPI\_CHxCONF[11:7] WL field for 9-bit word length.

5. Set the SPI1.MCSPI\_CHxCONF[6] EPOL bit to 1 for spi1\_cs0 activated low during active state.
6. Set the SPI1.MCSPI\_CHxCONF[1] POL bit to 0 for spi1\_clk held high during active state.
7. Set the SPI1.MCSPI\_CHxCONF[0] PHA bit to 0 for data latched on odd-numbered edges of the SPI clock.

#### **Clock Initialization and spi1\_cs0 Enable**

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI\_MODULCTRL[2] MS bit to 0 to provide the clock.
9. Set the SPI1.MCSPI\_CHxCTRL[0] EN bit to 1 (where x = 0) to enable channel 0.

#### **19.6.2.6.2.1.2 Write Operation**

1. Write 1 to the SPI1.MCSPI\_IRQSTATUS[0] TX0\_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI\_TX0 register to transmit the value.
3. If the SPI1.MCSPI\_IRQSTATUS[0] TX0\_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

#### **19.6.2.6.2.1.3 Read Operation**

1. Read the SPI1.MCSPI\_IRQSTATUS[2] RX0\_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI\_IRQSTATUS[2] RX0\_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

---

**Note:** Write and read operations can be performed simultaneously.

---

#### **19.6.2.6.3 Programming in Interrupt Mode**

This section follows the flow of [Figure 19-26](#).

1. Initialize software variables: WRITE\_COUNT = 0 and READ\_COUNT = 0.
2. Initialize interrupts: Write 0x7 in the SPI1.MCSPI\_IRQSTATUS[3:0] field and set the SPI1.MCSPI\_IRQENABLE[3:0] field to 0x7.
3. Follow the steps described in [Section 19.6.2.6.2.1.1, Mode Selection](#).
4. If WRITE\_COUNT = w and READ\_COUNT = w, write SPI1.MCSPI\_CHxCTRL[0] = 0x0 (x = 0) to stop the channel.

This interrupt routine follows the flow of [Table 19-16](#) and [Figure 19-28](#).

1. Read the SPI1.MCSPI\_IRQSTATUS[3:0] field.
2. If the SPI1.MCSPI\_IRQSTATUS[0] TX0\_EMPTY bit is set to 1:
  - a. Write the command/address or data value in SPI1.MCSPI\_TXx (where x = 0).
  - b. WRITE\_COUNT += 1
  - c. Write SPI1.MCSPI\_IRQSTATUS[0] = 0x1.
3. If the SPI1.MCSPI\_IRQSTATUS[2] RX0\_FULL bit is set to 1:
  - a. Read SPI1.MCSPI\_RXx (where x = 0)
  - b. READ\_COUNT += 1
  - c. Write SPI1.MCSPI\_IRQSTATUS[2] = 0x1

#### **19.6.2.6.4 Operations for the Second Slave (on Channel 1) in Polling Mode**

##### **19.6.2.6.4.1 Mode Selection**

The SPI1.MCSPI\_CHxCONF register (with x = 1) allows configuration of the operating mode:

1. Set the SPI1.MCSPI\_CH1CONF[18] IS bit to 0 for the spi1\_somi pin in receive mode.
2. Set the SPI1.MCSPI\_CH1CONF[17] DPE1 bit to 0 and the SPI1.MCSPI\_CH1CONF[16] DPE0 bit to 1 for the spi1\_somi pin in transmit mode.
3. Set the SPI1.MCSPI\_CH1CONF[13:12] TRM field to 0x0 for transmit-and-receive mode.

4. Write 0x3 in the SPI1.MCSPI\_CH1CONF[11:7] WL field.
5. Set the SPI1.MCSPI\_CH1CONF[6] EPOL bit to 0 for spi1\_cs1 activated high during the active state.
6. Set the SPI1.MCSPI\_CH1CONF[1] POL bit to 1 for spi1\_clk held low during the active state.
7. Set the SPI1.MCSPI\_CH1CONF[0] PHA bit to 1 for data latched on even numbered edges of spi1\_clk.

#### **Clock Initialization and spi1\_cs1 Enable**

The SPI1.MCSPI\_MODULCTRL[2] MS bit was set to 0 (providing the clock).

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI\_CH0CTRL[0] EN bit to 0 to disable channel 0, and set the SPI1.MCSPI\_CH1CTRL[0] EN bit to 1 to enable channel 1.

---

**Note:** Read and write operations for the second slave are identical to those for the first slave.

---

#### **19.6.2.6.4.2 Write Operation**

1. Write 1 to the SPI1.MCSPI\_IRQSTATUS[4] TX1\_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI\_TX1 register to transmit the value.
3. If the SPI1.MCSPI\_IRQSTATUS[4] TX1\_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

#### **19.6.2.6.4.3 Read Operation**

1. Read the SPI1.MCSPI\_IRQSTATUS[6] RX1\_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI\_IRQSTATUS[6] RX1\_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

---

**Note:** Write and read operations can be performed simultaneously.

---

### **19.6.3 Transfer Procedures with FIFO**

In the subsections below, the transfer procedures are described with FIFO using (MCSPI\_CHxCONF[27:28] FFER or/and FFEW = 1).

The MCSPI module allows the transfer of one or more words, according to different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

For these flows, the host process contains the main process and the interrupt routine, which is called on the IRQ signals or by an internal call if the module is used in polling mode.

#### **19.6.3.1 Common Transfer Procedure**

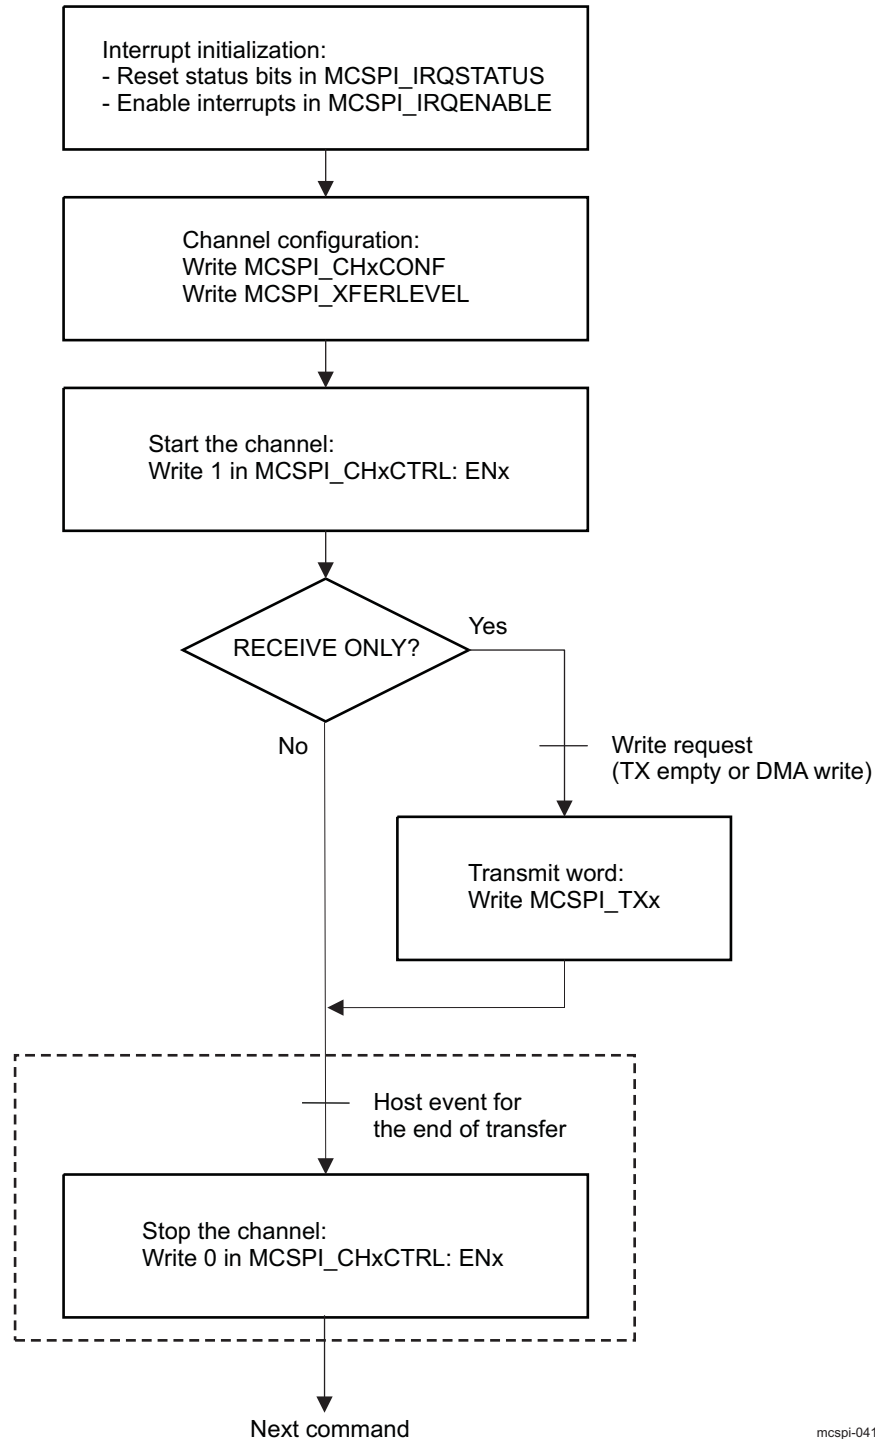

The common transfer sequence is the host sequence for a transfer of any type defined above.

In multichannel, only one channel can use the FIFO. Before enabling the FIFO for a channel (FFExW and FFExR bits in the MCSPI\_CHx\_CONF register), the host must ensure that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit/receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In slave mode, only channel 0 only can be activated. The correct spim\_csx line is chosen in the MCSPI\_CH0CONF register with the SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request is released by writing the MCSPI\_TXx register, even in receive-only mode (only one write request occurs in this case). [Figure 19-37](#) shows the main process of the common transfer sequence.

**Figure 19-37. Common Transfer Sequence/Main Process**

mcspi-041

The MCSPI module can start the transfer only after the first write request is released by writing the [MCSPI\\_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

This first write request can be managed by the IRQ routine or DMA handler, as are as other requests. It appears in [Figure 19-37](#) to show this point.

The end of the transfer (dotted line in [Figure 19-37](#)) is more complex and depends on the transfer type. [Table 19-17](#) describes the different types of end-of-transfer and the transfer types to which they are applicable.

**Table 19-17. End-of-Transfer Types**

Word Count	Transmit/Receive	Transmit Only	Receive Only
Yes	See <a href="#">Section 19.6.3.2</a> , <i>Transmit-Receive With Word Count.</i>	See <a href="#">Section 19.6.3.4</a> , <i>Transmit-Only.</i>	See <a href="#">Section 19.6.3.5</a> , <i>Receive-Only With Word Count.</i>
No	See <a href="#">Section 19.6.3.3</a> , <i>Transmit-Receive Without Word Count.</i>	See <a href="#">Section 19.6.3.4</a> , <i>Transmit-Only.</i>	See <a href="#">Section 19.6.3.6</a> , <i>Receive-Only Without Word Count.</i>

The sequence differs depending on whether word count is used ([MCSPI\\_XFERLEVEL](#): WCNT is set or not). The AEL and/or AFL values can be different, but they must be multiples of the word size in the FIFO: 1, 2, or 4 bytes, according to word length.

In these sequences, the transfer to execute has a size of N words.

When accessing the FIFO, only one word is written or read for each OCP access.

In these sequences, the number of words written or read for each write or read FIFO request is:

- write\_request\_size
- read\_request\_size

If they are not submultiples of N, the last request sizes are:

- last\_write\_request\_size (< write\_request\_size)
- last\_read\_request\_size. (< read\_request\_size)

The different sequences can be merged in one process to manage transfers of several types.

The end-of-transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

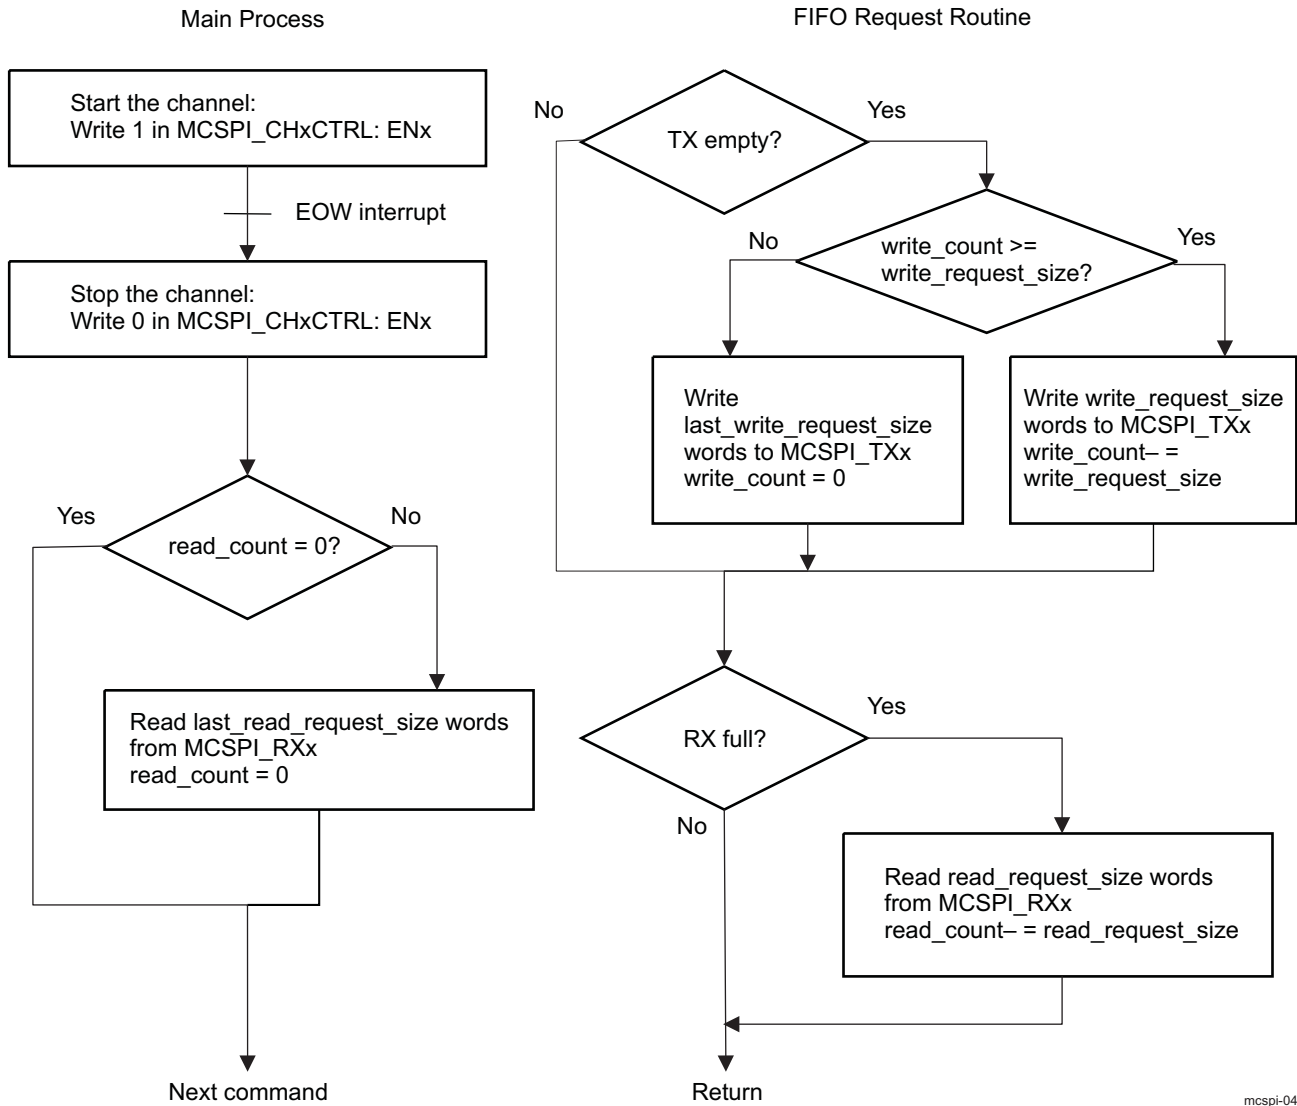

- write\_count = N
- read\_count = N
- last\_request = FALSE

They are initialized before starting the channel.

### 19.6.3.2 Transmit-Receive Procedure With Word Count (WCNT≠0)

Figure 19-38 shows the flow of a transfer in transmit-receive mode, with word count.

**Figure 19-38. Transmit-Receive With Word Count**

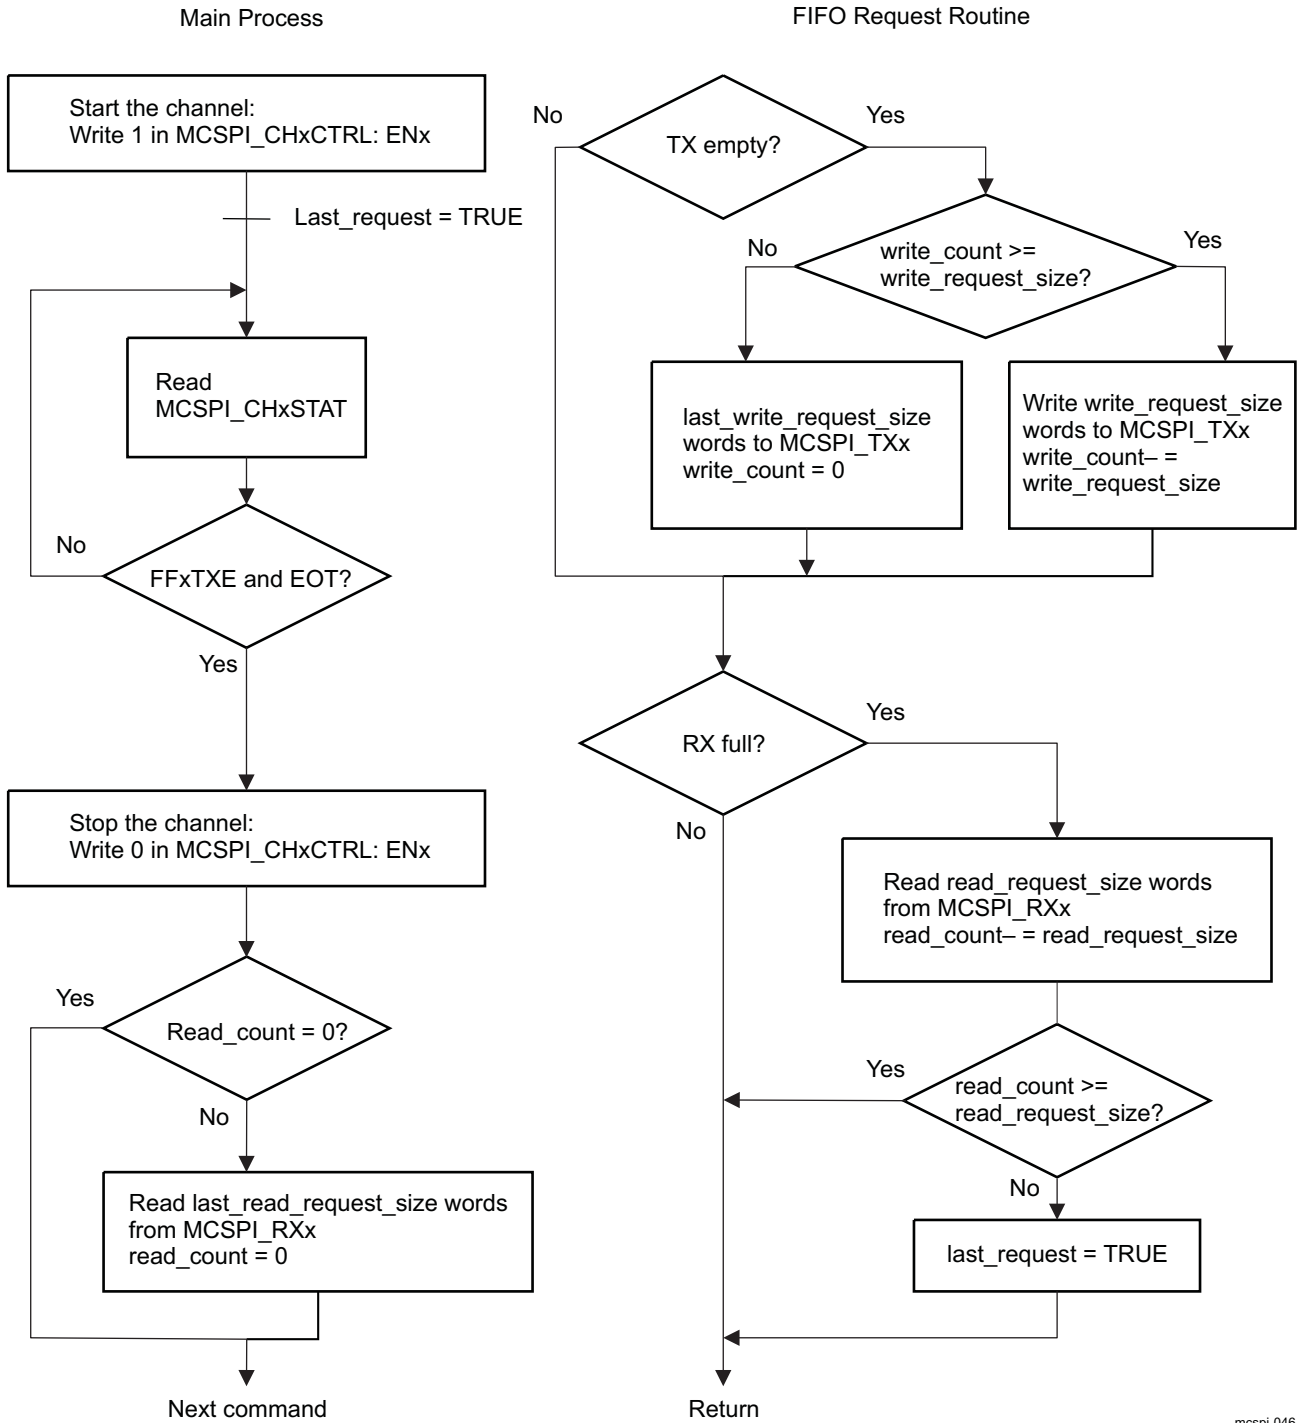

mcspi-042

19.6.3.3 Transmit-Receive Procedure Without Word Count (WCNT=0)

Figure 19-39 shows the flow of a transfer in transmit-receive mode, without word count.

Figure 19-39. Transmit-Receive Without Word Count

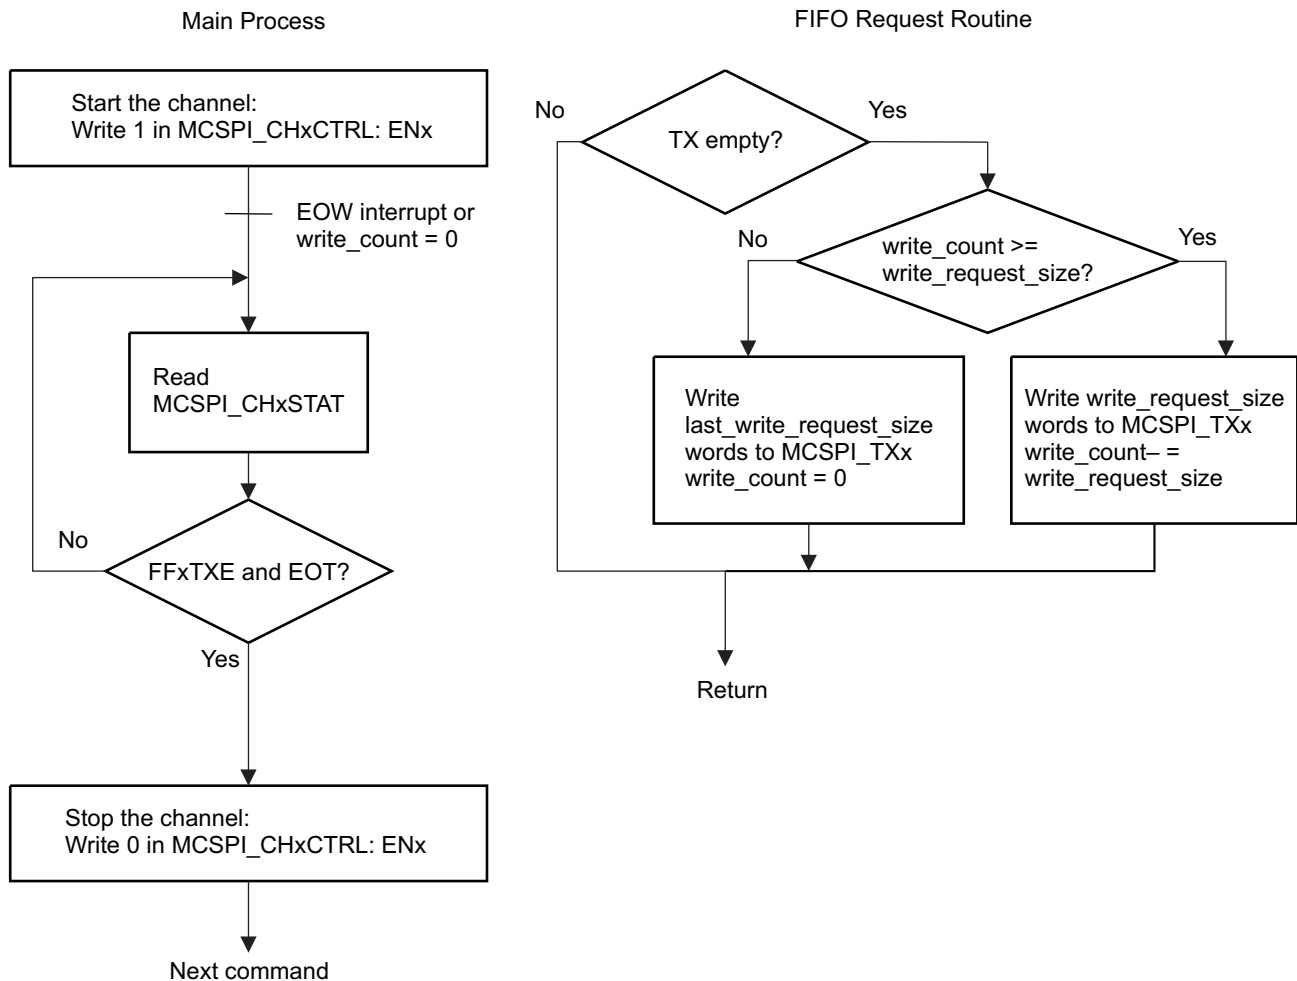

mcspl-046

### 19.6.3.4 Transmit-Only Procedure

Figure 19-40 shows the flow of a transfer in transmit only mode, with or without word count.

**Figure 19-40. Transmit-Only**

mcspi-047

The difference between word count enabled or not is the condition after starting the channel:

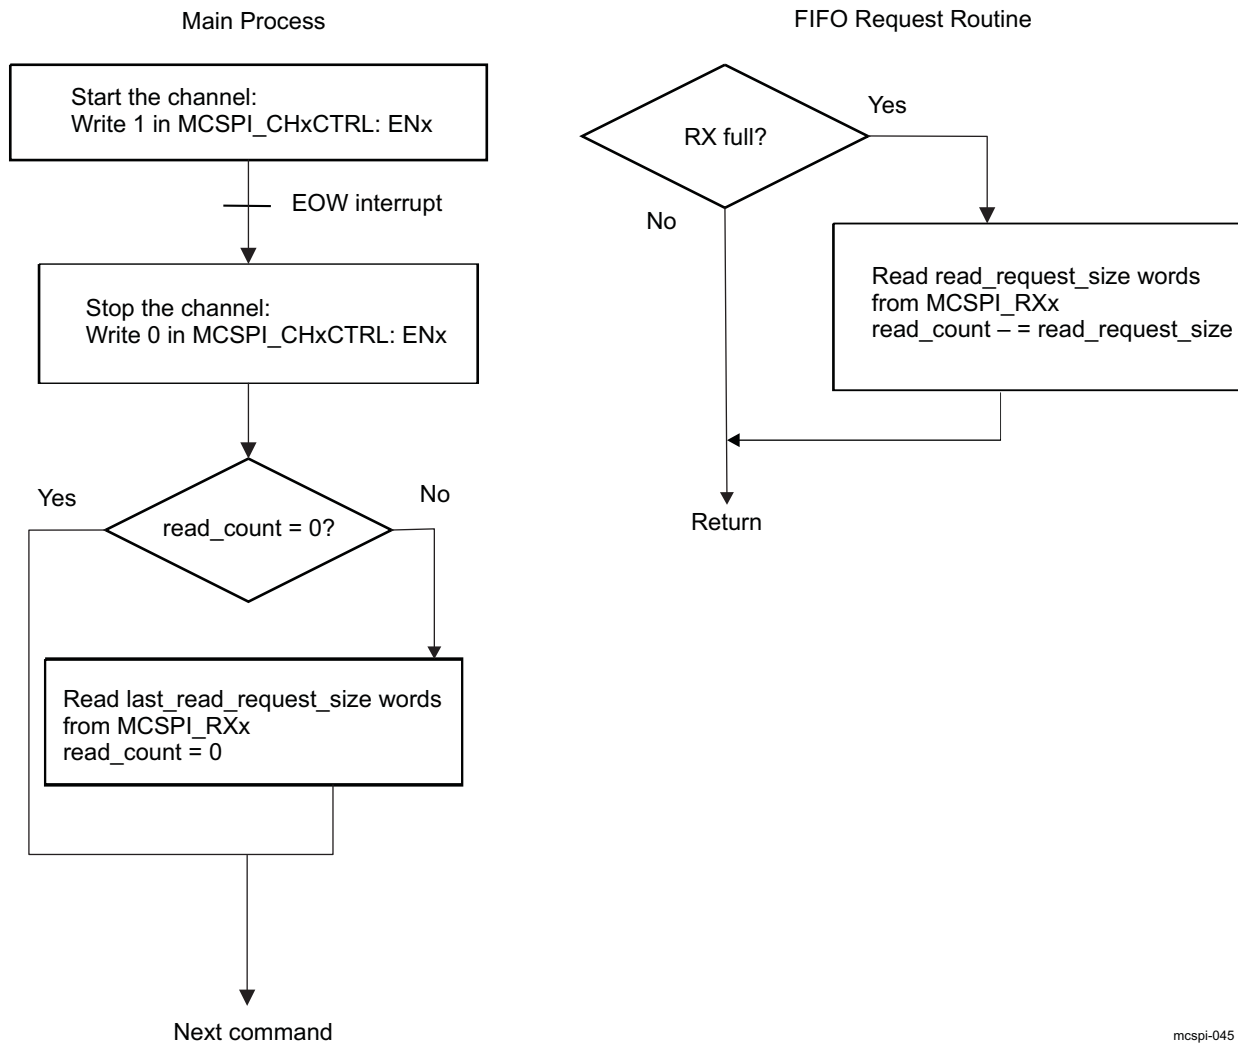

- Word count enable: Wait for EOW interrupt.
- Word count disable: Wait for write\_count = 0.

19.6.3.5 Receive-Only Procedure With Word Count (WCNT≠0)

Figure 19-41 shows the flow of a transfer in receive-only mode, with word count.

Figure 19-41. Receive-Only With Word Count

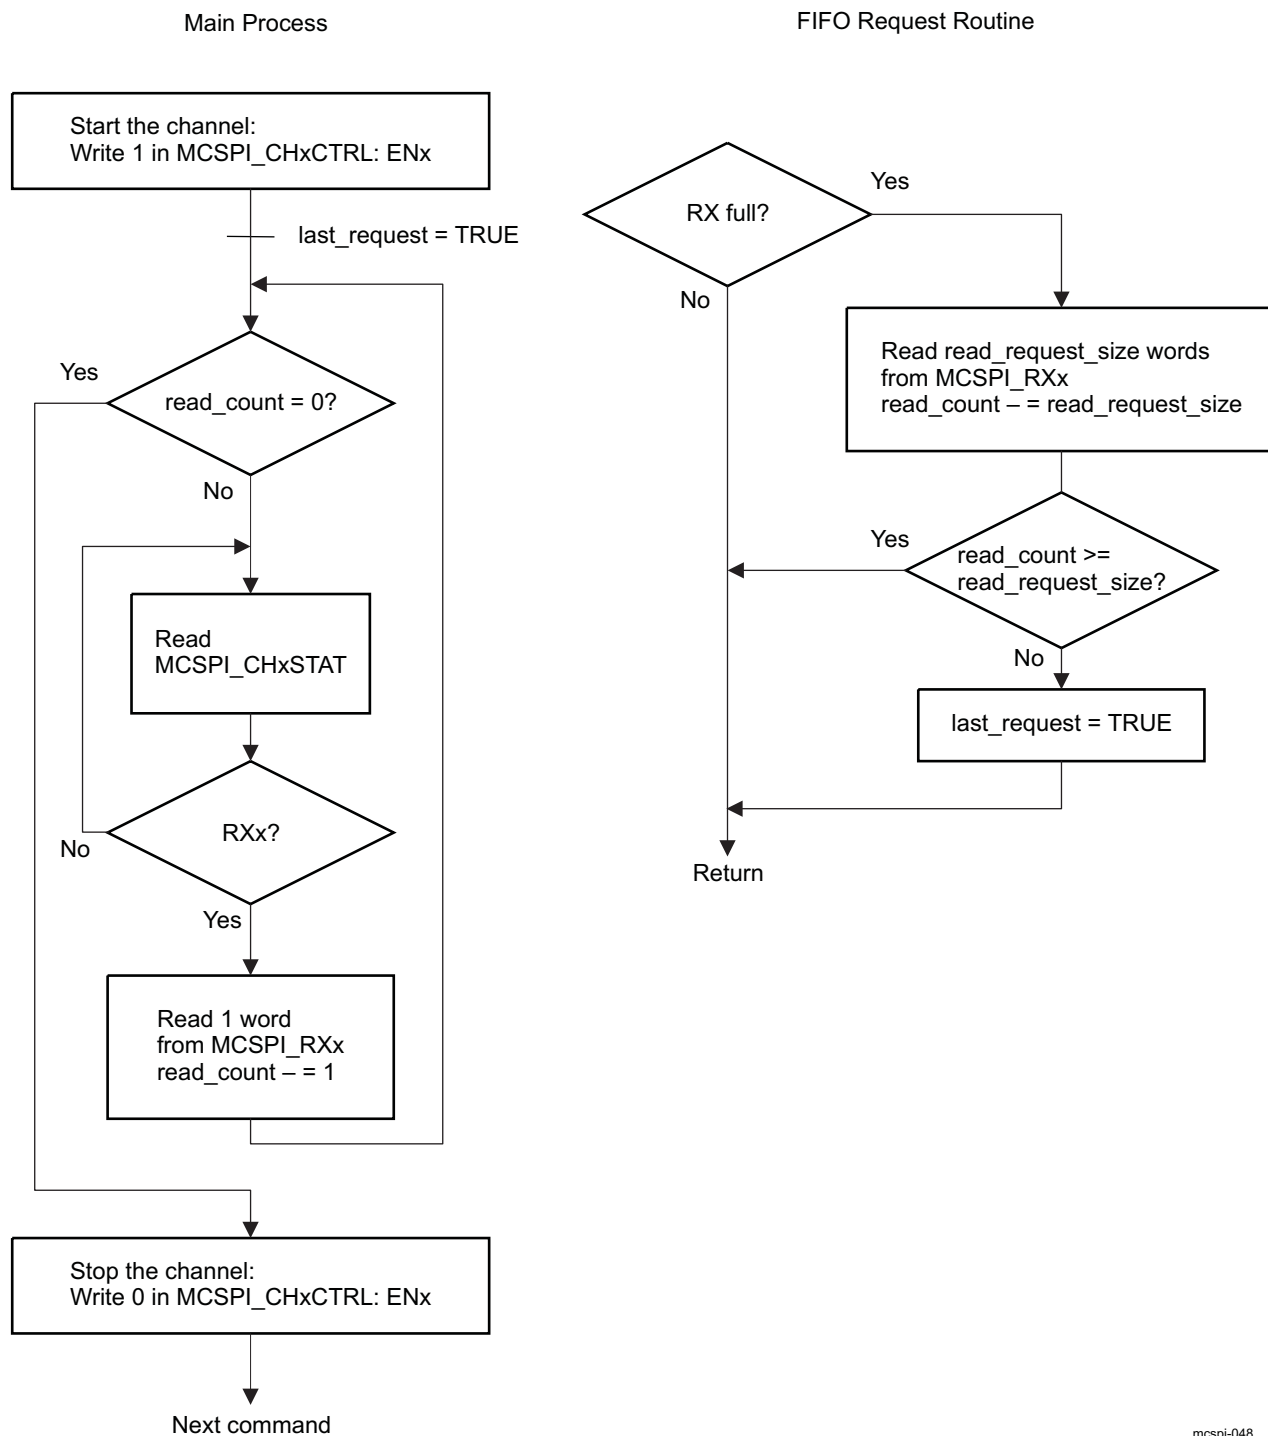

mcspi-045

### 19.6.3.6 Receive-Only Procedure Without Word Count (WCNT=0)

Figure 19-42 shows the flow of a transfer in receive-only mode, without word count.

**Figure 19-42. Receive-Only Without Word Count**

mcspi-048

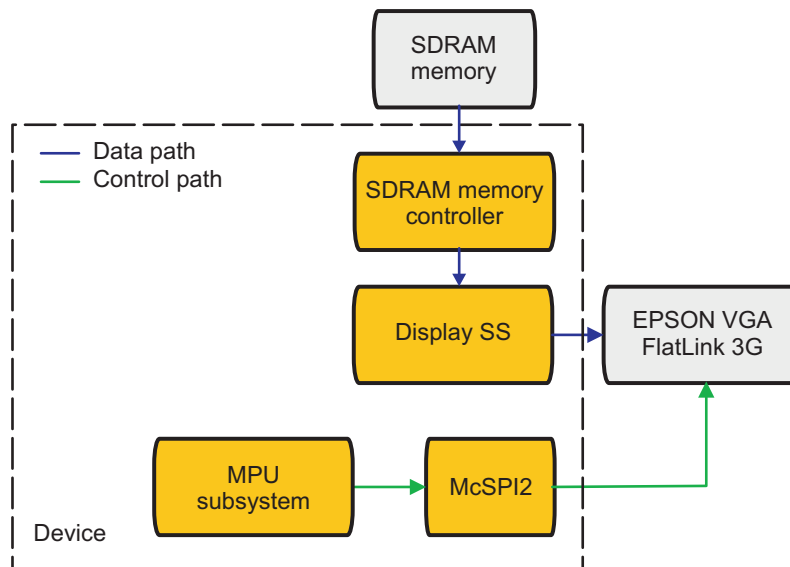

## 19.7 McSPI Use Cases and Tips

### 19.7.1 How to Configure the McSPI Interface When Connected with an EPSON VGA FlatLink™ 3G Device

#### 19.7.1.1 Overview

This section deals with configuring an EPSON VGA FlatLink™3G device through the McSPI interface. Before transferring data from the external SDRAM memory to the external EPSON VGA display (Figure 19-43), the display subsystem must be set up via the McSPI interface. Several commands must be sent to the EPSON VGA for its configuration.

Figure 19-43. Overview

108-037

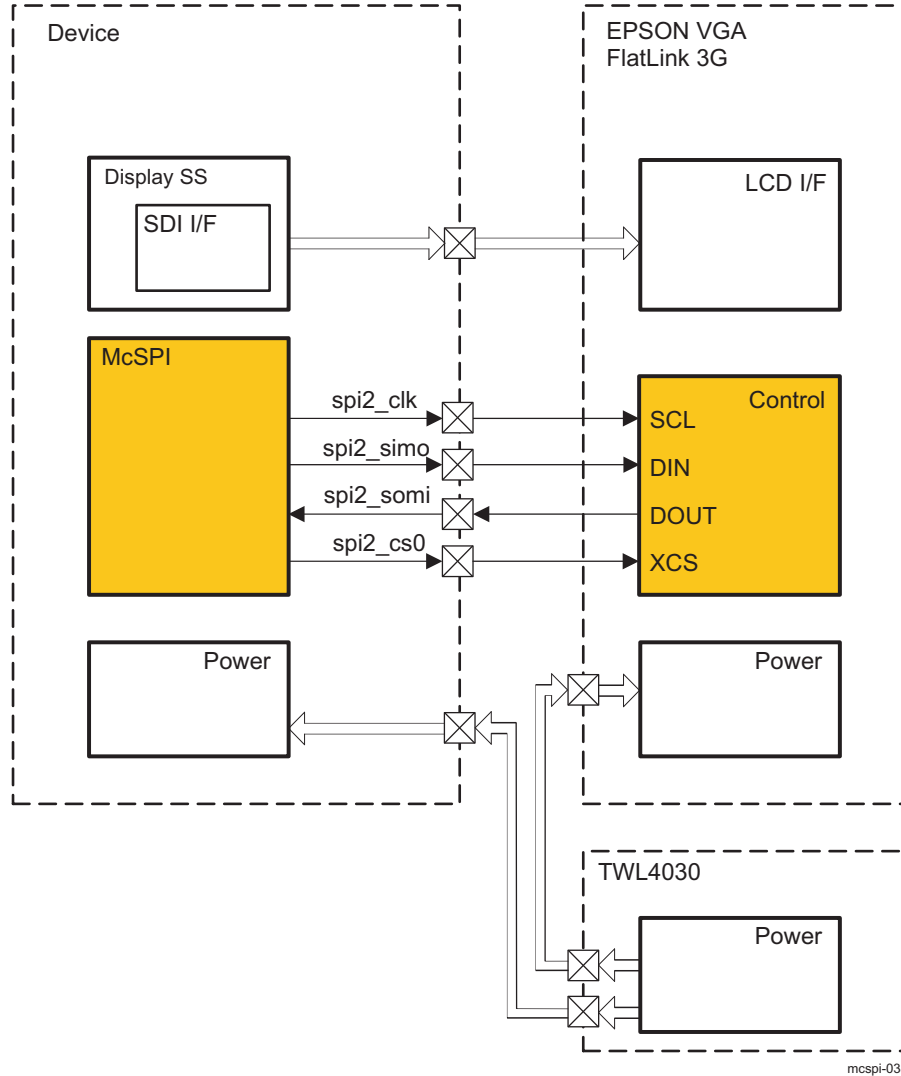

In this use case the configuration is the following:

- McSPI2 channel 0 in master mode, EPSON VGA display in slave mode
- Transmit-only and receive-only modes
- No DMA requests and no interrupts used: transmit and receive flag polling

#### 19.7.1.2 Environment

In this use case, the EPSON VGA is connected to the device through channel 0 of the McSPI instance 2 as shown in Figure 19-44 (through `mcspi2_somi`, `mcspi2_simo`, `mcspi2_cs0`).

The display clocks are provided to the EPSON VGA by the device display subsystem. The display configuration clock comes from the McSPI interface (`mcspi2_clk`).

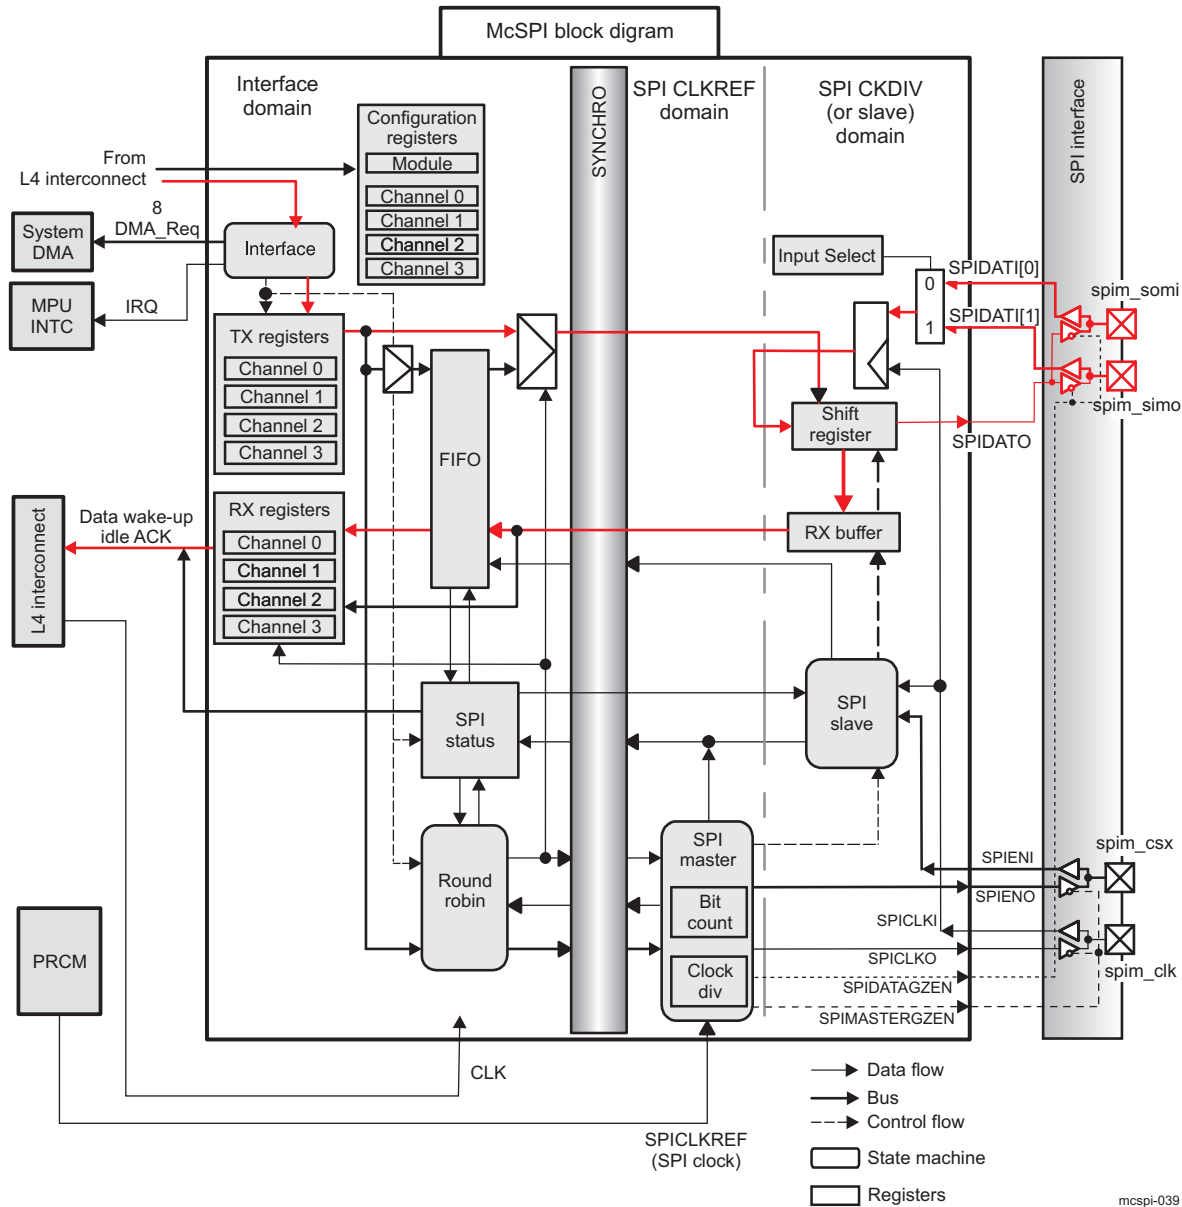

**Figure 19-44. Environment**

### 19.7.1.3 Data Path

In this use case, the McSPI2 manages the control path between the MPU subsystem and the EPSON VGA FlatLink™ 3G.

- Display configuration commands are transmitted via the channel 0 transmit register (TX Registers) and the shift register.
- A display status is read via the shift register, the receive buffer, and the channel 0 receive register (RX Registers).

Figure 19-45. McSPI Data Flow

mcspi-039

### 19.7.1.4 Programming Flow

The initialization of the EPSON VGA is done in five steps:

1. McSPI module configuration
2. Send a 'SOFT RESET' command to the EPSON VGA
3. Send a 'SLEEP OUT' command
4. Send a 'DISPLAY ON' command
5. Send a 'READ DISPLAY STATUS' command and receive status data.

The four EPSON VGA commands needed in the EPSON VGA configuration are described in [Table 19-18](#).

**Table 19-18. EPSON VGA Configuration Commands**

	D/CX	D7	D6	D5	D4	D3	D2	D1	D0	Dummy bit
SOFT RESET (001h)	0	0	0	0	0	0	0	0	1	n/a
SLEEP OUT (011h)	0	0	0	0	1	0	0	0	1	n/a
DISPLAY ON (029h)	0	0	0	1	0	1	0	0	1	n/a
READ DISPLAY STATUS (009h and dummy bit '0')	0	0	0	0	0	1	0	0	1	0

The following subsections describe each of these initialization steps.

#### 19.7.1.4.1 McSPI Module Configuration

Before configuring the external display VGA, the multi-channel serial port interface must be initialized as detailed in the following steps:

1. Enable the McSPI2 functional and interface clocks through the PRCM.CM\_FCLKEN1\_CORE[18] EN\_MCSPi2 and PRCM.CM\_ICLKEN1\_CORE[18] EN\_MCSPi2 fields.
2. Proceed to a McSPI software reset through the [MCSPI\\_SYSCONFIG\[1\]](#) SOFTRESET field. The SOFTRESET bit is automatically reset by hardware.
3. Poll the [MCSPI\\_SYSSTATUS\[0\]](#) RESETDONE field to check the software reset status.
4. Disable channel 0 through the [MCSPI\\_CHXCTRL\[0\]](#) EN field (with x=0).
5. Disable all interrupts ([MCSPI\\_IRQENABLE](#) register) then clear interrupt status register ([MCSPI\\_IRQSTATUS](#)). Interrupts are disabled once at this stage. Even if some interrupts of the [MCSPI\\_IRQSTATUS](#) register are set, no interrupt can go out to the MPU subsystem.
6. Set the module in Master mode and multichannel mode through the [MCSPI\\_MODULCTRL](#) register.
7. Configure channel 0 in transmit-only mode, with a word length of 9-bit through the [MCSPI\\_CHXCONF](#) register (with x=0). A word length of 9 bits is required to transmit the required command (SOFT RESET, SLEEP OUT, or DISPLAY ON) to the EPSON display, as detailed in [Table 19-18](#). Those 9 bits are serially transmitted on spi2\_simo in the sequence D/CX, D7 to D0.

[Table 19-19](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

**Table 19-19. McSPI Configuration Registers Print**

Register Name (with x=0)	Physical Address	Value	Value Description
PRCM.CM_FCLKEN1_CORE[18]	0x4800 4A00	0x1	Enable McSPI2 functional clock
PRCM.CM_ICLKEN1_CORE[18]	0x4800 4A10	0x1	Enable McSPI2 interface clock
<a href="#">MCSPI_SYSCONFIG[1]</a>	0x4809 A010	0x1	Initiate a software reset
<a href="#">MCSPI_SYSSTATUS</a>	0x4809 A014	0x0000 0001	The RESETDONE field is set at 1 when the reset is complete
<a href="#">MCSPI_CHXCTRL</a>	0x4809 A034	0x0000 0000	Disable channel 0
<a href="#">MCSPI_IRQENABLE</a>	0x4809 A01C	0x0000 0000	Disable all interrupts
<a href="#">MCSPI_IRQSTATUS</a>	0x4809 A018	0x0001 777F	Clear all interrupts
<a href="#">MCSPI_MODULCTRL</a>	0x4809 A028	0x0000 0000	Master mode, multichannel

**Table 19-19. McSPI Configuration Registers Print (continued)**

<a href="#">MCSPI_CHxCONF</a>	0x4809 A02C	0x0001 2453	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 9-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo
-------------------------------	-------------	-------------	---

#### 19.7.1.4.2 'SOFT RESET', 'SLEEP OUT' and 'DISPLAY ON' Commands

Once the McSPI interface is configured, three commands must be send to the external display VGA: a software reset to reinitiate the external display, a 'SLEEP OUT' command to wake it up, and a 'DISPLAY ON' to turn on the display. Those three commands follow the same procedure, described here below, only the command opcode changes.

1. Enable channel 0 through the [MCSPI\\_CHxCTRL\[0\]](#) EN field (with x=0).
2. Write the command opcode to the [MCSPI\\_TXx](#) (with x=0) register so that it could be transmitted to the external display VGA. To transmit the SOFT RESET command, write 001h in the [MCSPI\\_TXx](#) (with x=0) register. To transmit a SLEEP OUT command write 011h and to transmit a DISPLAY ON command write 029h.
3. Poll the [MCSPI\\_CHxSTAT\[1\]](#) TXS field (with x=0) to check for transmit status. When the word has been transmitted, TXS is automatically set to 1.
4. Disable channel 0 through the [MCSPI\\_CHxCTRL\[0\]](#) EN field (with x=0).

[Table 19-20](#) shows all registers to be configured with the required value for the those commands and the use case values.

**Table 19-20. Display Configuration Registers Print**

Register Name (with x=0)	Physical Address	Value	Value Description
<a href="#">MCSPI_CHxCTRL</a>	0x4809 A034	0x0000 0001	Enable channel 0
<a href="#">MCSPI_TXx</a>	0x4809 A038	0x001 0x011 0x029	Transmit a 'SOFT RESET' command to the EPSON VGA display Transmit a 'SLEEP OUT' command Transmit a 'DISPLAY ON' command
<a href="#">MCSPI_CHxSTAT[1]</a>	0x4809 A030	0x1	The word in <a href="#">MCSPI_TXx</a> has been transmitted when the TXS flag is set to 1
<a href="#">MCSPI_CHxCTRL</a>	0x4809 A034	0x0000 0000	Disable channel 0

#### 19.7.1.4.3 'READ DISPLAY STATUS' Command

Once the EPSON VGA display is initialized, a 'READ DISPLAY STATUS' command is sent to the external display VGA to read and check the status of the component, such as Partial mode, Sleep In mode, Display status, Horizontal and Vertical Synchronization On or Off states.

The 'READ DISPLAY STATUS' command is not 9- but 10-bit long because the EPSON VGA display requires a dummy cycle between the transmission of the last command bit (D0 in [Table 19-18](#)) and the reception of the first data bit (the display status data is 32-bit long). In other words, a dummy bit is added as less significant bit of the command. Hence, those 10 bits are serially transmitted on spi2\_simo in the sequence D/CX, D7 to D0, dummy bit.

1. Set the module in Master mode and single channel mode through the [MCSPI\\_MODULCTRL](#) register.
2. Configure channel 0 in transmit-only mode, with a word length of 10-bit through the [MCSPI\\_CHxCONF](#) register (with x=0).
3. Enable channel 0 through the [MCSPI\\_CHxCTRL\[0\]](#) EN field.

4. Shift left of one bit the command opcode 009h so that the required dummy bit ('0') can be sent after the D/CX and D7 to D0 bits to the EPSON VGA display. Refer to [Table 19-18](#) for more information. Then, write this command (012h) to the [MCSPI\\_TXx](#) (with x=0) register so that it could be transmitted to the EPSON VGA display.
5. Poll the [MCSPI\\_CHxSTAT\[1\]](#) TXS bit (with x=0) to check transmit status. When the word has been transmitted, TXS is automatically set to 1.
6. Read the [MCSPI\\_CHxSTAT\[1\]](#) RXS bit to check receive status. If data has already been received (RXS is set to 1) read the [MCSPI\\_RXx](#) (with x=0) receive register; this will automatically deactivate the RXS flag (RXS is automatically cleared).
7. Configure channel 0 in receive-only mode, with a word length of 32-bit through the [MCSPI\\_CHxCONF](#) register.
8. Poll the [MCSPI\\_CHxSTAT\[1\]](#) RXS bit to check receive status. When data has been received, RXS is automatically set to 1. The 32-bit display status information is available in the McSPI2 channel 0 receive register: [MCSPI\\_RXx](#) (with x=0).
9. Set channel 0 in transmit-only mode through the [MCSPI\\_CHxCONF](#) register.

[Table 19-21](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

**Table 19-21. Display Status Check Registers Print**

Register Name (with x=0)	Physical Address	Value	Value Description
<a href="#">MCSPI_MODULCTRL</a>	0x4809 A028	0x0000 0001	Master mode, single channel
<a href="#">MCSPI_CHxCONF</a>	0x4809 A02C	0x0011 24D3	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 10-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo
<a href="#">MCSPI_CHxCTRL</a>	0x4809 A034	0x0000 0001	Enable channel 0
<a href="#">MCSPI_TXx</a>	0x4809 A038	0x0000 0012	Send a 'READ DISPLAY STATUS' command. See <a href="#">Table 19-18</a> .
<a href="#">MCSPI_CHxSTAT[1]</a> TXS	0x4809 A030	0x1	The word in <a href="#">MCSPI_TXx</a> has been transmitted if the TXS flag is set to 1
<a href="#">MCSPI_CHxSTAT[0]</a> RXS	0x4809 A030	-	Read RXS flag. Data has been received in <a href="#">MCSPI_RXx</a> if the RXS flag is set to 1
<a href="#">MCSPI_RXx</a>	0x4809 A03C	-	Read <a href="#">MCSPI_RXx</a> only if the RXS bit is equal to 1 (this is a dummy read that will automatically clear the RXS flag)
<a href="#">MCSPI_CHxCONF</a>	0x4809 A02C	0x0011 1FD0	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 32-bit Receive-only Receive on spi2_somi Transmit on spi2_simo
<a href="#">MCSPI_CHxSTAT[0]</a> RXS	0x4809 A030	0x0	Data has been received in <a href="#">MCSPI_RXx</a> when the RXS flag is set to 1.
<a href="#">MCSPI_CHxCONF</a>	0x4809 A02C	0x0011 2453	Back in transmit-only mode Receive on spi2_somi Transmit on spi2_simo

## 19.8 McSPI Register Manual

### 19.8.1 McSPI Instance Summary

Table 19-22 lists the McSPI instances.

**Table 19-22. McSPI Instance Summary**

Module Name	Base Address	Size
MCSP11	0x4809 8000	4Kbytes
MCSP12	0x4809 A000	4Kbytes
MCSP13	0x480B 8000	4Kbytes
MCSP14	0x480B A000	4Kbytes

### 19.8.2 McSPI Register Summary

Table 19-23 lists the McSPI registers. Each register has a 32-bit width. Table 19-24 through Table 19-50 describe the register bits.

**Table 19-23. McSPI Register Summary**

**Table 19-28. MCSPI\_SYSSTATUS**

<b>Address Offset</b>	0x14	
<b>Physical Address</b>	0x4809 8014	<b>Instance</b> MCSPI1
	0x4809 A014	MCSPI2
	0x480B 8014	MCSPI3
	0x480B A014	MCSPI4
<b>Description</b>	This register provides status information about the module excluding the interrupt status information	
<b>Type</b>	R	
<b>Write Latency</b>	Immediate	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																RESETDONE															

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Reserved for module specific status information. Read returns 0	R	0x00000000
0	RESETDONE	Internal Reset Monitoring 0x0: Internal module reset is on-going 0x1: Reset completed	R	0

**Table 19-30. MCSPI\_IRQSTATUS**

<b>Address Offset</b>	0x18	
<b>Physical Address</b>	0x4809 8018	<b>Instance</b> MCSPI1
	0x4809 A018	MCSPI2
	0x480B 8018	MCSPI3
	0x480B A018	MCSPI4
<b>Description</b>	The interrupt status regroups all the status of the module internal events that can generate an interrupt	
<b>Type</b>	RW	
<b>Write Latency</b>	Immediate	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
Reserved																EOW	WKS	Reserved	RX3_FULL	TX3_UNDERFLOW	TX3_EMPTY	Reserved	RX2_FULL	TX2_UNDERFLOW	TX2_EMPTY	Reserved	RX1_FULL	TX1_UNDERFLOW	TX1_EMPTY	RX0_OVERFLOW	RX0_FULL	TX0_UNDERFLOW	TX0_EMPTY

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Reads returns 0	RW	0x0000
17	EOW	End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by <b>MCSPI_XFERLEVEL</b> [31:16] WCNT bit field.  Write 0x0: Event status bit unchanged. Read 0x0: Event false. Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
16	WKS	Wake-up event in slave mode when an active control signal is detected on the <code>spim_csx</code> line programmed in the <b>MCSPI_CHxCONF</b> [SPIENSLV] field (where x=0 only)  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
15	Reserved	Reads returns 0.	RW	0x0
14	RX3_FULL	MCSPI_RX3 register is full (only when channel 3 is enabled)  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
13	TX3_UNDERFLOW	MCSPI_TX3 register underflow (only when channel 3 is enabled) <sup>(1)</sup>  Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
